HISTORICAL CLIMATOLOGY emerged as a discipline in the late nineteenth and early twentieth century, the first major work of synthesis being by Brooks[1]. The subject's existence was at first fitful, but in the 1940s, 50s and 60s, the enthusiasm of men like Flohn, Manley, Schove, and above all, Lamb, successfully demonstrated the interest and importance of this field of study. In recent years, interest in historical climatology has grown considerably, and significant contributions have been made not only by natural scientists but also by historians (especially Ladurie[2]). This interest has arisen through an increased awareness of man's susceptibility to the vagaries of climate (the Russian wheat failure of 1972, and the Sahelian drought come readily to mind), through the realisation that climatic conditions very different from today have occurred in the recent past, and through the maxim of the acturial approach to climatic forecasting, "the past is the key to the future". In spite of this progress, no comprehensive methodology of historical climatology has been established, with the result that there exists no ready means for assessing the significance of individual contributions and, thus, of what has been achieved in the field as a whole. In view of this fact, we believe that the most useful method of reviewing the subject is to examine the problems which need to be universally recognised and overcome before historical climatology may be said to rest on a firm methodological and factual footing. In so doing, we shall as far as space permits criticise and evaluate past and current work in the field.

Fig. 1 Flow chart showing data useful for reconstructing past climates and delineating the contribution of historical climatology. The separate categories often overlap, and some of the more important interactions are shown.

Scope of historical climatology

The task of reconstructing the climates of the past involves the use of many different types of evidence (Fig. 1). The successful exploitation of this material demands a varied range of skills and techniques which effectively define specialised subdisciplines of climatology. Historical climatology is best thought of as one such subdiscipline, which focuses on the study of written materials (excluding records of modern standardised instrumental observations) which bear on past climate. These materials include, not only meteorological information, but also data on such phenomena as glacier movements, phenological events and other more or less indirect indicators of climatic change.

The distinctive contribution of historical climatology ends with the advent of instrumental observations, embracing pressure and temperature measurements, which effectively began in the mid-seventeenth century. The earliest series relate to Europe. In most other parts of the world, instrumental data extend back no further than the late eighteenth century, and in many locations span less than 100 years. The earliest instrumental series, moreover, pose many problems of interpretation, and the precise dates from which they may be regarded as acceptably accurate and standardised are debatable. The elucidation of early instrumental data may be regarded as within the scope of historical climatology, but the techniques involved[3–5] are specialised ones and will not be discussed here.

Apart from early instrumental records, the written sources of climatic data are legion. They include: (1) ancient inscriptions; (2) annals, chronicles, and so on); (3) records of public administration and government, whether imperial, national, provincial or local; (4) private estate records; (5) maritime and commercial records; (6) personal papers (diaries, correspondence, and so on); (7) scientific and proto-scientific writings (including journals of non-instrumental weather observations).

How far back into the past can the historical climatologist penetrate with the aid of these records? The answer varies with location. It is impossible to give a comprehensive guide to the earliest dates from which materials exist in different areas, because much essential exploratory work to discover possible sources has not yet been carried out. For example, it seems likely that the written remains of the brilliant and complex cultures of the Middle East and India would provide rich materials for the historical climatologist, but at present they remain almost totally unexploited. However, Table 1 provides enough information to indicate the main patterns of distribution. It can be seen that in certain areas the vision of the historical climatologist is limited to only a few decades preceding the establishment of standardised instrument observations. But for considerable areas of the world there are materials extending over centuries, and in favoured locations over thousands of years.

Even in areas for which early materials survive, the distribution of sources is by no means uniform over time. For example, the European evidence for the period before about AD 1000 is very scanty. It is appreciably richer, but still very

0028-0836/78/0276—0329$01 00

Table 1 Earliest dates from which written evidence of climatic phenomena survives in selected areas

Area	Earliest written evidence (approximate dates)
Egypt	3000 BC
China	2500 BC
Southern Europe	500 BC
Northern Europe	0
Japan	AD 500
Iceland	AD 1000
North America	AD 1500
South America	AD 1550
Australia	AD 1800

imperfect, for the period AD 1000–1600. Thereafter many more materials are available, but it is only in the late seventeenth and eighteenth centuries that sources become really abundant. Equally, there are great differences in quality between different types of materials, with nearly all the best sources relating to the most recent periods.

As the sources are of such variable quality and quantity, a rigorous methodology is required to reject unsuitable and inadequate material and to extract the maximum amount of information from what remains. In the following, a methodology is discussed with particular reference to data verification and analysis of information.

Data verification

Written statements about the past are not equally reliable, and indeed much material which purports to record historical events is seriously misleading. Historians have developed a sophisticated methodology for evaluating sources and rejecting unreliable information. Plainly, historical climatologists need to be similarly aware, both of the need for source criticism, and of the available critical techniques. Scientists attempting to reconstruct past climates have, in fact, often been ignorant on one or both of these counts (see, for example, criticisms in the works of Gottschalk[6-8], Alexandre[9], and Bell and Ogilvie[10]).

A critical discussion of the sources of data available to historical climatologists will reveal the significance of this fact. There exist many eighteenth-, nineteenth-, and twentieth-century compilations and syntheses of historical climatic information (the most important are listed by Bell and Ogilvie[10]). At first sight, these works seem to provide a conveniently ready-made data bank, and it is therefore not surprising that they have formed the basis of numerous attempts at climatic reconstruction. In reality many of these compilations and syntheses are highly defective as data sources, and work founded on them is liable to be inaccurate. Their deficiencies may be summarised as follows. First, their transmission of the original data is often inaccurate and incomplete. Compilations and syntheses often consist of abridged, translated, paraphrased, or condensed material. Second, many of the works under discussion include errors introduced by the author or compiler, the most common mistake being misdating. Third and most fundamentally, most compilations fail to distinguish adequately (if at all) between reliable and unreliable sources. It is true that some very recent works[6-8,11,12] are models of critical awareness. As a whole, however, the available compilations and syntheses comprise a mishmash of valuable and worthless data, and to use them uncritically for the purposes of climatic reconstruction is unacceptable. An illustration of the amount of valueless material contained in two widely used compilations is given in Table 2. In constructing this Table we have subjected the compilations of Hennig[13] and Weikinn[14] to a critical historical analysis (see below) and counted the number of items which survive this criticism. Such items are described as 'verified'.

When scientists attempt to penetrate beyond compilations and modern syntheses to the materials on which they are based, or if they seek new data, they are faced with the problem of distinguishing between reliable and unreliable sources. Various criteria may be applied to test reliability. The tests are numerous and complex, and here only the basic principles are indicated. Most fundamentally, it is necessary to examine the nature of the source to assess whether, or how far, the writer was actually interested in recording real events, for not everything which looks like history as we understand it was intended as such. Of further tests, the most important are those based on the principles of contemporaneity, propinquity, and faithful transmission. Recorded statements cannot be regarded as reliable unless it can be shown either (1) that the writer lived close in time and space to the events he purports to describe, and recorded his observations either immediately or within a very short time after these events had taken place, or (2) that he had access to first-hand oral or written reports and accurately transmitted the information derived from them.

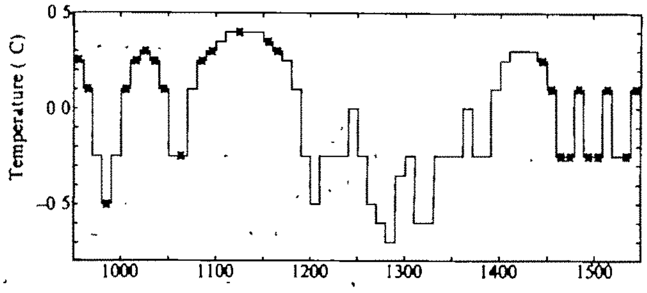

Fig. 2 Bergthórsson's original decadal estimates of temperature in Iceland showing the sparseness of data which remain after a critical examination of the historical evidence. The decades for which there is no historically acceptable information are marked with crosses (Information supplied by Astrid Ogilvie.)

Many materials, especially narrative sources such as chronicles which were often subject to constant addition and revision, emerge badly from such tests. It is frequently found that sources are in whole or in part either (1) slavishly derivative and therefore of no independent value; (2) inaccurately and corruptly derivative; (3) spurious, fabricated for some particular

Table 2 Historical reliability of two European weather compilations for the period AD 0–1000

Century (AD)	Hennig[13] Total no. of seasons described	Hennig[13] % Of seasons verified	Hennig[13] Additional information by season	Weikinn[14] Total no of seasons described	Weikinn[14] % Of seasons verified	Weikinn[14] Additional information by season	Total no of reliable seasonal descriptions available
0–99	20	50	2	8	88	5	12

Total	272	28	49	89	79	55	125

The additional information' refers to reliable material which we have extracted from other primary sources purpose such as to assert the rights and claims of the author's monastery; or (4) of literary, philosophical, or religious significance but of no value as records of events.

Much of the data which historical climatologists have hitherto used have been drawn, either directly or more often by way of compilations, from such unreliable sources, and are therefore subject to error. The most important errors are: (1) inaccurate or uncertain dating of particular events; (2) spurious multiplication of events through failure to recognise that accounts recorded under different dates in various sources in fact relate to a single event; (3) acceptance of accounts which are distortions or amplifications of original observations (for example, purely local events may appear through the distortions of later writers as major catastrophes covering a large area); (4) inclusion of events for which there is no reliable evidence whatsoever (such 'non-events', moreover, tend to be artificially multiplied through being assigned to different dates in subsequent derivative accounts).

These errors are not randomly distributed and are therefore not self-correcting. On the contrary, the problem of unreliable data is so great that decadal or even 50-yr series are liable to be grossly inaccurate if unverified material is used. These points may be illustrated by reference to the work of Bergthórsson[15-17] and Lamb[18,19], although it must be stressed that the studies in question were only presented as tentative preliminary analyses. Figure 2 shows the shortcomings of the early part of Bergthórsson's decadal temperature series for Iceland, itself based on the work of Thoroddsen[19]. The decades marked with a cross are those for which, as critical analysis reveals, no reliable climatic information is available. Only eight of the first 22 decades of the record have any reliable climatic information, and many of these decades have only one or two items. For the period AD 1431–1560 only one item of reliable climatic information is available. Clearly it is quite impossible to construct decadal temperature estimates for much of the period, and even 50-yr averages cannot be estimated before AD 1100 or between AD 1450 and 1550. Bergthórsson himself may have had misgivings about the decadal series shown here as it has not been published in its original form: nevertheless, it has subsequently been reproduced by other authors[15,16].

Lamb[9] has published decadal indices for England, Central Europe and the Russian Plain for the period AD 1100 onwards (discussed further in the next section). As with the Icelandic reconstruction, these indices are partly based on compilations which are now known to be unreliable, and, on this ground alone, they must be regarded as suspect: they are currently being revised in the Climatic Research Unit. Although the results of this revision are not yet complete, it is instructive to compare Lamb's indices with the work of the historians Titow[21] and Alexandre[11,12].

Fig. 3 Comparison of winter temperatures (December, January, February; °C) from three European sites for the period 1684–1738. Short-term fluctuations have been smoothed out by using a 9-yr Binomial filter. The Zürich record[30] is based partly on the observed correlation between Zürich and central England temperatures, but also on records of local snowfall and duration of snow cover. (We have filled some minor gaps in the Zürich record using the Zürich–England correlation.) Part of the central England record[31] (1707–22) is based on instrumental data from Delft.

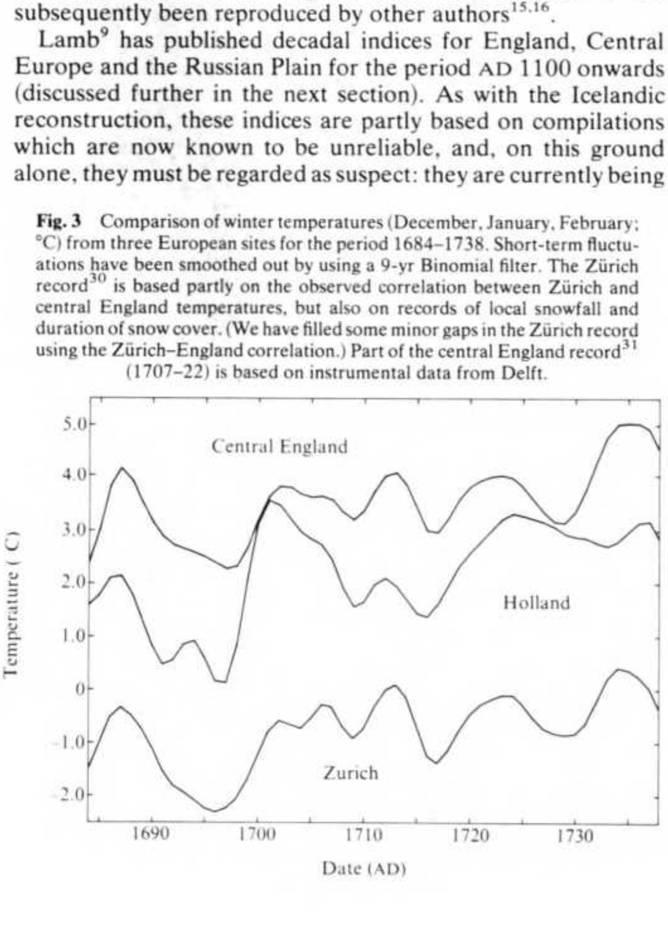

Fig. 4 A frost fair on the River Thames early in 1863.

Consider first the summer wetness indices for England for the period AD 1200–1350. Lamb (ref. 18, page 32) has compared his results for these 15 decades with primary data extracted by Titow[21] from the manorial account rolls of Winchester Cathedral. The two records are well correlated ($r = 0.77$). On the other hand, Lamb's English winter severity indices for the period AD 1100–1400 seem to be less well-founded. Here, there is no independent record for England, but there is a similar record available for Belgium constructed by Alexandre. (Alexandre[11,12] has analysed the compilation of Vanderlinden[22] in detail and found it to be seriously unreliable. In order to fill the data gaps which resulted from his source criticism, Alexandre examined a large number of primary sources which Vanderlinden had not used. From this new body of data he then calculated decadal indices using the method developed by Lamb (see below).) Comparison of Lamb's and Alexandre's indices shows only a low correlation ($r = 0.2$, compared with a correlation coefficient of 0.9 for decadal winter temperatures between AD 1750 and 1940). Although this low correlation may be partly the result of real changes in meteorological factors, it must be largely attributed to the variable, but generally poor quality of the compilations used by Lamb.

These strikingly contrasting results indicate the need for a re-examination of the data which form the basis for the currently accepted historical climate record. It is essential to build up a data bank of historical information of unquestionable reliability.

Analysis and interpretation

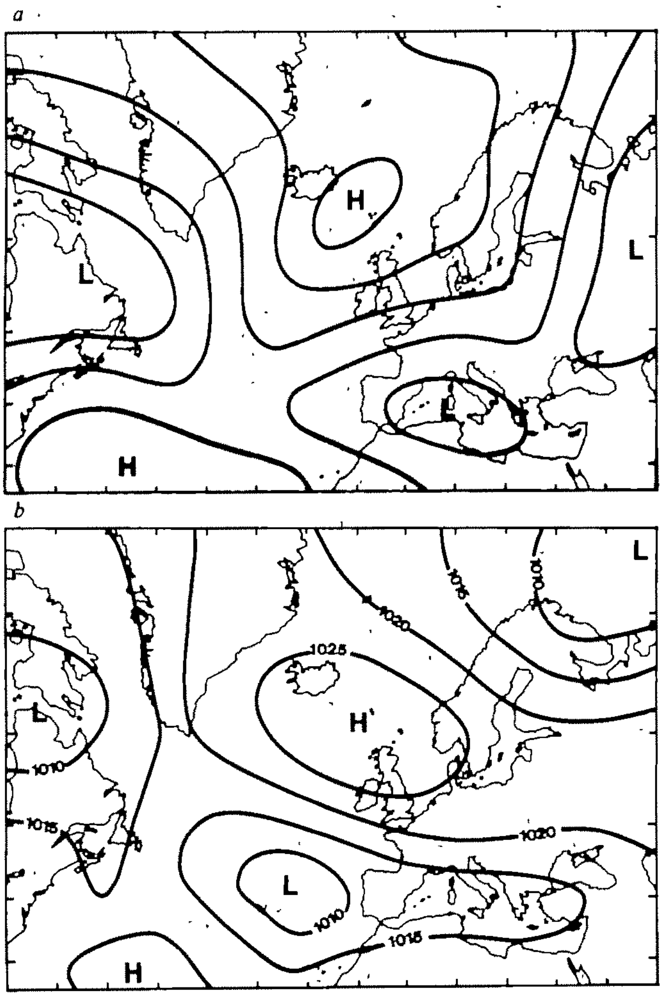
Given reliable data, the next task of the historical climatologist is to use different types of documentary evidence to produce time series which are, as far as possible, comparable with modern meteorological records. Four steps are involved: historical analysis of the material; quantification; transformation into meteorological variables; and the addition of long-term trends where necessary.

Modern instrumental observations provide the nearest approach to an objective and comprehensive record of climatic phenomena. Historical climatic data, on the other hand, embody distortions and omissions reflecting the various personal and cultural biases of past observers. The ways in which phenomena were perceived and categorised varied from period to period, place to place, and observer to observer. So also did the principles by which phenomena were selected for the record. Even the manner of recording—terse or verbose, sparsely or profusely detailed, matter-of-fact or poetically embellished—affects the information content of the record.

In the final analysis, these factors limit the quality and quantity of the information which can be derived from the documents. But they also pose problems of interpretation, in effect obscuring what information the materials do contain. This obscurity must, as far as possible, be removed by subjecting the sources to rigorous textual analysis to establish the meanings of words and categories and to determine the nature of biases. This may be achieved by reference to specialised historical knowledge of the intellectual and social milieux which gave rise to the texts, and by internal analysis of individual sources and comparison between sources relating to the same set of phenomena. Moreover, as Moodie and Catchpole[23,24] have demonstrated, the methods of analysis should be codified and systematised to ensure that individual analysts, faced with the same body of materials, will derive essentially the same information.

Although a universal set of rules cannot be defined, the analyst must ask of the verified data these basic questions: (1) Why was the information recorded? How did the purposes of the writer bias his perception and selection of phenomena? (2) What is the precise significance of such categories as 'frost', 'drought', 'flood', 'sea-ice', and so on? (3) What is the significance of terms of degree? For example, what weight should be attached to expressions like "The greatest . . . that hath been known in the memory of any man living".? (4) When did the event occur, and for how long? Changes in the calendar have occurred at different times in different places, and the precise timing of an event is not always important to the past recorder. Furthermore, the timespan covered by terms like 'summer' and 'winter' varies from record to record. (5) Where did the event occur? Did the recorder distinguish between local and 'foreign' events? The weather diary of Merle[25], kept variously in Lincolnshire or Oxford from 1337–44, is a mild example of the sort of confusion which can arise.

Fig. 5 Preliminary reconstruction of the winter 1683–84 circulation pattern (*a*), and the pressure map for January 1963 (*b*). (1683–84 reconstruction supplied by H H Lamb) Both seasons exhibited strong blocking patterns with persistent E to NE winds over England The normal winter pattern shows a belt of low pressure at the latitude of Iceland, and south-westerly winds over England, and the patterns here are highly anomalous



The next stage in analysis is to quantify the information in terms of standard meteorological variables. In general, two steps are necessary: quantification in terms of a numerical index followed by calibration of the index in terms of a variable such as temperature or precipitation. Certain types of information are already numerical in form, and if they are homogeneous and systematic they can be calibrated directly by correlation between the original record (or a modern-day equivalent) and a meteorological parameter provided there is a sufficient period of overlap between the records. One of the earliest examples of this type of analysis is the winter temperature reconstruction derived by Flohn[26] from the meteorological journals of Tycho Brahe[27] (Hven, Denmark, 1582–97) and Haller[28] (Zürich, 1546–76). Flohn found from modern instrumental observations that the ratio of days of snowfall to days of rainfall in winter was well correlated with winter temperature. Using the snow and rain records of Brahe and Haller, Flohn was able to show that winters in Zürich were about 1.3 °C colder in 1561–76 than in 1546–61; whereas the winters on Hven from 1582–97 were about 1.5 °C below those around the turn of the twentieth century. The implied severity of the latter part of the sixteenth century accords with the wind direction observations given by Brahe and analysed as early as 1876 by La Cour[27].

Similarly, De Vries[29] has calibrated data on freezing of water in Dutch canals in terms of winter temperatures to extend the record of Dutch winter temperatures back to 1634; and Pfister[30] has used data on snow falls and duration of snow cover from various historical sources to estimate winter temperatures near Zürich back to 1683. Figure 3 compares De Vries' and Pfisters' results with Manley's[31] central England temperature record (based on instrumental data) for the period 1684–1738. All three records show the striking cold of the 1690s, a decade without subsequent parallel.

Unfortunately, most historical information is not so readily quantifiable in terms of meteorological variables, as the data are generally discontinuous, non-homogeneous, and show a marked bias towards the recording of extreme events. In such cases the documentary evidence must first be transformed into a numerical index. One of the first to do this was Brooks[1] who derived 50-yr indices of wetness and winter severity for Europe using data from a number of compilations. Lamb[19] refined this work by calculating decadal indices for Europe near 50°N at three longitudes, 0°E (England), 25°E (Central Europe) and 50°E (the Russian Plain), back to AD 1100. Lamb's indices may be defined as follows. For 'winter severity', the index is $C-M$, where C is the number of unmistakably cold winter months in a decade and M the number of unmistakably mild months; and for 'summer wetness', $W-D$, where W is the number of summer months with evidence of frequent rains and D is the number of months with evidence of drought per decade.

One of the underlying assumptions of indexing, and the basis for expecting indices to reflect the meteorological variables, temperature and precipitation, is that there are few, if any, severe seasons for which we have no written record. Previous historical climatologists have tended to believe that there are few such data gaps, mainly because they had no way of knowing the poor quality of their sources. We now know that there are gaps in the record, especially before AD 1500, and that early impressions were false because of the amount of duplicated, fabricated and erroneous information in the widely used compilations.

This raises a question: how many gaps are permissible before decadal index values become unrepresentative? Different types of index show differing sensitivity to missing data. 'Difference' indices, as used by Lamb, are quite sensitive, whereas 'ratio' indices show less sensitivity. (An example of a ratio index for winter severity is $(C-M)/(C+M)$ where C and M are the

INTERNATIONAL CONFERENCE ON CLIMATE AND HISTORY

8-14 July 1979, at the

CLIMATIC RESEARCH UNIT

Director: Prof. H. H. Lamb

UNIVERSITY OF EAST ANGLIA,
NORWICH, U.K.

The conference will take place at the University of East Anglia, Norwich, England, during the five-day period 8-14 July 1979. A social programme and excursions will be arranged for participants and accompanying persons.

The purpose of this conference is to bring together climatologists, historians and archaeologists from throughout the world to discuss climate and its possible impact on past and present societies.

Some financial assistance may become available to the organizing committee to facilitate travel and/or subsistence of a limited number of participants.

Potential contributors and participants are requested to notify as soon as possible and, in any case, not later than 31 December 1978:

The Conference Secretary
(Climate and History Conference),
Climatic Research Unit,
School of Environmental Sciences,
University of East Anglia,
Norwich, NR4 7TJ,
United Kingdom.

Announcing a Major New Journal for 1979

JOURNAL OF THE AUTONOMIC NERVOUS SYSTEM

EDITOR-IN-CHIEF: Chandler McC. Brooks, Distinguished Professor of State University of New York, State University of New York, Downstate Medical Center, Department of Physiology, Box 31, 450 Clarkson Avenue, Brooklyn, New York, 11203, U.S.A.

Editorial Policy:
The objective of this journal will be to publish new information concerning the structure and function of the autonomic nervous system. Papers will be considered that deal with: the embryology, differentiation, and development of its structures and actions; its central and peripheral components; the interconnections and interactions between its parts; its mechanism of action upon tissues and organ systems; the central control processes which regulate its actions; its integrative function in initiating, organizing and directing behavior; and its role in the determination of emotional and physical states of the body. The involvement of this system in learned or conditioned behavior and the part it plays in determining the nature of responses to situations and stimuli, will also be of interest. Preference will be given to papers which not only describe structural attributes but also relate them to functional potentialities, and also to those papers dealing with actions of parts which include valuable pointers to their significance.

Combining high scientific quality and originality, the JOURNAL OF THE AUTONOMIC NERVOUS SYSTEM will publish mainly primary research papers and occasional reviews, providing an essential source of information for researchers in the field.

First issue scheduled for July 1979.

1979 Volume I (1 volume in 3 issues).

M

ICE AGES
Solving the Mystery
John Imbrie and Katherine Palmer Imbrie

In 1971 the National Science Foundation organised the CLIMAP project to study changes in the climate of the earth over the past 700,000 years. Out of their analytical work came an exciting by-product: confirmation of the correctness of one of the several theories about what causes ice ages to occur.

This book was written by one of the principal scientists of the CLIMAP group and his daughter, a writer. It presents the recent findings and puts them into perspective. It tells the story of ice ages: what they were like, why they occurred, and when the next one is due.

"It is satisfying that at last we have a work which brings us up to date on a scientific mystery whose solution will literally dictate the future of humanity."
Dr. Stephen H. Schneider, deputy head of the climate project of the National Center for Atmospheric Research.

FLOODS
A Geographical Perspective
Roy C. Ward
Focal Problems in Geography series

This study of major flood problems ranges from the hydrological causes of floods, and their prediction and routing, to a survey of man's response when confronted by serious flooding. Each of the world's major flood-areas is considered, and particular reference is made to floods as geomorphological agents.

number of cold and mild months, respectively.) The sensitivity of indices can be tested by a Monte Carlo type of simulation where one starts with an artificially constructed (but realistic) complete record and progressively introduces more and more random gaps until there is a significant change in the average index value for an ensemble of decades. Such simulations show that ratio indices can tolerate small gaps in the record. (Equally important, they indicate that ratio indices are robust to uncertainties in the perception and/or actual frequency of extremes.)

The second step in quantification is to convert from index to meteorological parameter. Here the method is to correlate the index values with instrumental temperature or precipitation data over an overlap period. If a significant correlation cannot be established then the index itself is of doubtful value, but if there is a correlation then it can be used to interpret index values before the overlap period directly in terms of meteorological variables. Lamb[32] found that the correlation coefficient between summer wetness and late summer (July plus August) precipitation was 0.91, and the correlation between winter severity and mean winter temperature (December, January, February) was −0.87. However, neither index shows any significant correlation with summer temperatures. We note again that extrapolation back in time, even using the above high correlations, is suspect because, whereas the index values are reliable for the correlation period, their reliability is increasingly uncertain earlier in the record.

Detail from *A Winter Scene with Skaters near a Castle* (about 1609) by Hendrick Avercamp (Netherlands)

Courtesy Trustees, National Gallery, London

The third step in producing meteorological time series from historical data is to introduce long-term fluctuations. It has already been noted that historical data (excluding the most easily quantifiable items discussed initially) tend to be biased towards the reporting of extreme events. But 'extreme' here is not absolute, and is only relative to the observer's own idea of what is normal, which in turn is largely determined by his own experience. Long-term trends in the norm go unobserved, particularly because they are small relative to year to year fluctuations. As a crude meteorological instrument, man tends to act as a high pass filter and his subjective observations show only short-term fluctuations about an ever-changing norm. The response of this filter is uncertain: for example, a trend may show up as a series of extreme years giving the appearance of a step-function change in climate.

Detail from *The Castle of Muiden in Winter* (1658) by Van Beerstraaten (Netherlands)

Courtesy Trustees, National Gallery, London

This problem has long been realised by climatologists (see, for example, Brooks (ref. 1 pp. 329–330) and the solution suggested by Brooks still applies. This is to use either proxy data, or records which are not subject to filtering, to derive long-term trends independently, and to use these as the background for shorter-term fluctuations. Glacier fluctuations, pollen records, lake levels, tree line changes, vegetation limits and others are suitable. Some of these items may themselves derive from historical documents and so require care in compilation and analysis, whereas others are imperfectly understood as climatic proxies and can only be used after detailed individual studies of their responses to climate.

A more ambitious use of historical data is to construct a time series of maps of seasonal circulation patterns based on qualitative data from different locations. Such maps provide a synthesis of the diverse types of data which are available for Europe and the North Atlantic. Starting with a well distributed set of climatic descriptions pertaining to a particular season (or month), putative isobars can be drawn so that the implied wind pattern and the positions of centres of cyclonic and anticyclonic activity are consistent with the descriptive evidence. The principle involved is the same as that used by twentieth-century meteorologists to extend the surface pressure patterns on synoptic maps outside the region for which pressure data are available. Wind direction data are particularly useful for this type of analysis. The results depend on the experience of the analyst whose performance can be tested by using descriptive material from times when instrumental pressure maps are available. An example of this work is shown in Fig. 5, a reconstruction for the severe winter of 1683–84 (see also Fig. 4), arguably the most severe winter in England since 1659, and one of the most severe for Europe as a whole (possibly surpassed by 1708–09; ref. 33). The pressure map for January 1963 is shown for comparison: the similarity is

Dutch winter scene (seventeenth century engraving)

Mary Evans Picture Library

striking and reinforces earlier comments by Manley[34] on these two winters.

Using the reliable historical information which is now available, it should be possible to reconstruct circulation maps for many of the extreme seasons in Europe back to at least AD 1500, covering the worst period of the 'Little Ice Age'. The Little Ice Age is a period which is unique in the record of the past 3,000 years at least[35]. Most importantly, it has no equal in the period of instrumental meteorology, and may provide information on 'no analogue' situations which might recur in the future. But is this period just one where extreme events similar to those of today occurred more frequently; or were the extremes of the seventeenth century in some way fundamentally different from those of today? This type of analysis may help us to answer this question.

Conclusions

We have tried here to show a few of the shortcomings of existing research in historical climatology, tempered by some of its successes, and its potential for the future. The main defect in previous work is that much of it can now be seen to have been based on the sands of unreliable data. We have demonstrated the significance of this in two ways: by analysing some of the commonly used sources to find out the extent of unreliability (see Table 2), and by comparing some accepted reconstructions with more historically acceptable analyses. We believe that, at the very least, the details of shorter time scale fluctuations are subject to considerable doubt, and that revisions are essential. Nevertheless, although many of the studies published to date are open to criticism, we would emphasise that their authors were the pioneers in a developing science, whose efforts have aroused scientific and public interest. The most appropriate way of appreciating their work is to develop more rigorous methods through the application of established historical techniques and the refinement of current methods of quantification. We believe that this will result in a significant improvement in man's knowledge of past climates.

We thank Astrid Ogilvie for access to her verified data for Iceland, and H. H. Lamb for the 1683–84 reconstruction used in Fig. 5. This work was supported by grants from the Rockefeller Foundation (M. J. I. and T. M. L. W.) and the US Department of Commerce (D. J. Underhill), the latter through the US National Oceanic and Atmospheric Administration. We thank J. Craddock, H. H. Lamb and G. Manley for useful discussions.

Tree-ring evidence of past climatic variability

Valmore C. LaMarche, Jr

Laboratory of Tree-Ring Research, University of Arizona, Tucson, Arizona 85721

The increasingly visible impact of climatic variability on human affairs lends a sense of urgency to the task of better understanding the workings of the Earth's climatic system. Actual instrumental observations of climate are relatively short, and we must therefore turn to other sources for information about past climates to help develop and test the models that may enable us to predict climatic anomalies such as prolonged droughts or a series of severe winters. Tree-rings are one of the best sources of climatic proxy information. They can provide long, accurately dated, year-by-year records at many points around the globe, and bridge the gap between recent instrumental or historical data and the longer but more generalised geological records. Variations in the width of annual rings reflect the influence of climatic factors that limit the biological processes governing ring formation within a tree. Study of reconstructions of long records of a variety of climatic and related variables, such as temperature, precipitation, stream runoff and barometric pressure over periods of several hundred to several thousand years strongly suggests that the climate of the past century or so is not representative of the conditions that have frequently prevailed over long periods. Proxy records are thus a great help in our efforts to anticipate or predict future climate, which may be significantly different from the recent climatic past.

GREATER understanding of the global climatic system has become an increasingly important goal of scientific endeavour in a world that is faced with an expanding population and increasing pressure on energy, water and food resources. Growing awareness of the problem of climatic variability and its impact on human affairs is demonstrated by a series of recent major reports by the US National Academy of Sciences[1–3], the Australian Academy of Science[4], the Science Council of

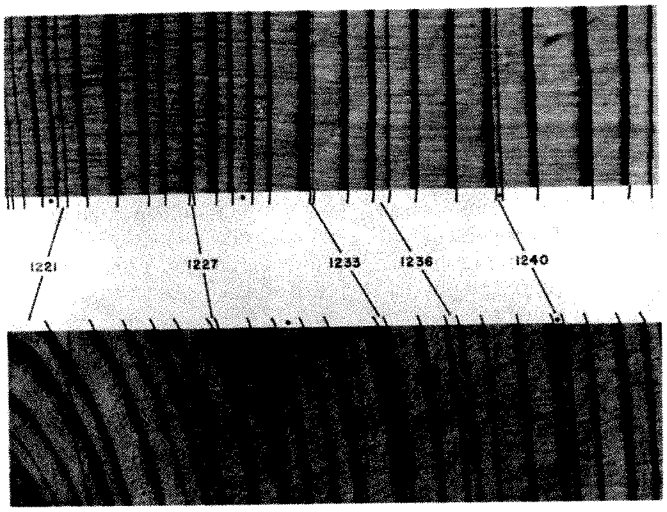

Fig. 1 Climatic sensitivity and crossdating. Douglas fir (*Pseudotsuga menziesii*) beam from a late thirteenth century Indian ruin in northern Arizona shows distinctive sequences of wide and narrow rings reflecting rainfall variations. The narrow rings represent years that were drier than normal.

Canada[5], and by other national and international agencies.

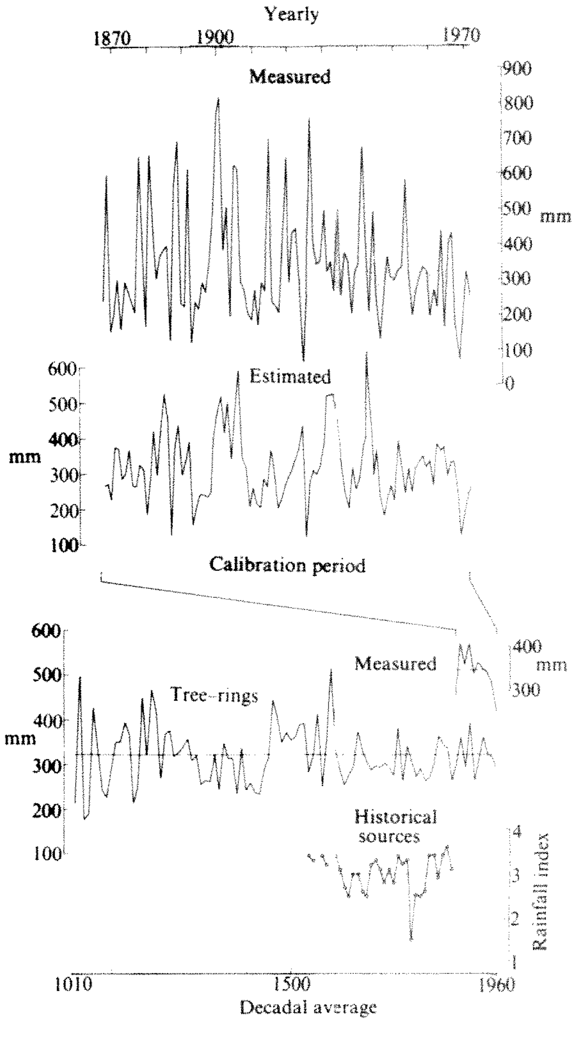
The basic problem is that we do not know enough about the workings of the climatic system, which includes the oceans, land areas, and ice sheets as well as the atmosphere. Because of its complexity, predictions about the future behaviour of the system must ultimately come from physically based numerical models which embody our understanding of the processes involved. However, the existing observational data base may be inadequate for the development and verification of models capable of accurate climatic forecasts. One of the most serious constraints that could emerge is that a model 'tuned' to generate the present climate with adequate precision may not be able to reproduce climatic states that have existed in the geologically recent past, and that could recur in the immediate future. An important step in the verification of a model (with important implications for its use as a forecasting tool) would be to test whether it can generate not only plausible mean conditions, but also time series with variance spectra similar to those of data from the real world. Observational, historical and climatic proxy data for time periods independent of those used in development are thus needed for complete model verification.

Palaeoclimatic records

The records of actual instrumental observations of climate are inadequate for study of climatic variations on time scales of decades to millennia[1]. Continuous records of surface elements such as atmospheric pressure, temperature and precipitation go back 300 yr at most, and then in only a few localities in the Northern Hemisphere. In most areas, reasonably complete surface coverage exists for only the past 50–100 yr. Upper air soundings have been regularly made on a global basis for only the past two or three decades, and satellite observations are an even more recent innovation. Fortunately, information about climate before the beginning of instrumental observations can be obtained from study of a wide variety of physical and biological phenomena that respond in some way to climate. The "unique value of proxy data for studies of climatic change" has been recognised by the US Committee for the Global Atmospheric Research Program[1]. Among its principal recommendations is a programme for the preparation and maintenance of climatic data banks, and of analyses based on both current and palaeoclimatic data. It envisages the use of palaeoclimatic records for setting boundary conditions and for model verification and also views these records as our only documentation of the extreme states of which the Earth's climatic system is capable. The WMO-ICSU Joint Organising Committee[6] also states that "special efforts should be made to locate, make available, and analyze . . . a wide variety of human recordings and natural indicators of climatic conditions in earlier centuries and millennia . . .". Here, the emphasis is on the use of time-series analysis of proxy records to improve understanding of physical processes and to explore the possibilities of empirical prediction, as well as on verification of numerical models. According to the Geophysics Research Board[2], the design of more robust water-resource systems would be helped by palaeoclimatic research which "offers a promising approach to better estimates of past climatic variability and drought probabilities." Palaeoclimatic data thus promise to play an important part in further development of climate theory as well as in more immediate practical applications.

Because climate varies over a large range of time and space scales, it is important to identify the time periods and geographical areas in which data would be most critical in helping to understand the existing climate. The Earth is now, and has been for some 10,000 yr, in an interglacial climatic state, characterised by relatively high sea levels, relative warmth, and largely ice-free conditions in temperate latitudes. However, even the present interglacial can be subdivided into periods of distinctively different climate. The last globally significant change seems to have taken place about 3,000 yr ago. Widespread cooling and associated circulation changes at this time are fairly well documented in the Northern Hemisphere. Smaller but at least locally significant variations have occurred in more recent

Fig. 2 Rainfall estimation from tree-ring data. Total annual precipitation at Santiago, Chile, is calibrated with ring-width indices at a nearby site using simple linear regression methods (correlation coefficient 0.65). This relationship is first used to estimate rainfall for the calibration period of actual meteorological observations (above), and then for the total length of the tree-ring record (below). The dendroclimatic reconstruction compares fairly well with semiquantitative information from historical sources as given by Lamb[30].



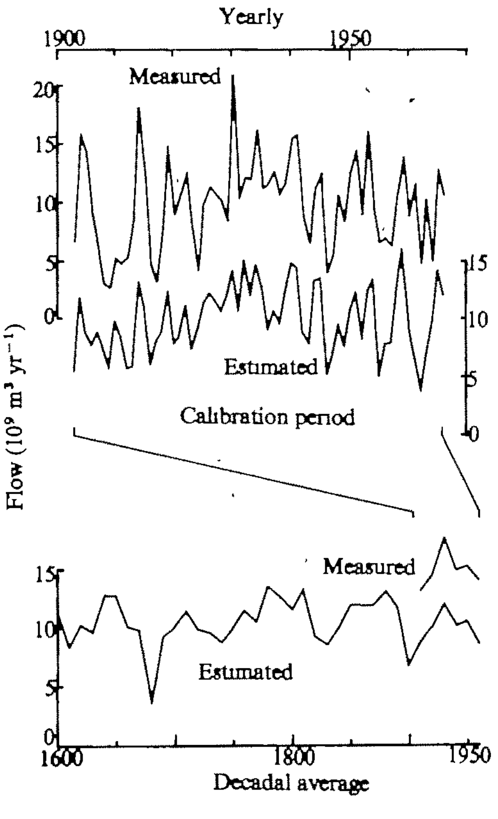
times. As pointed out by Kutzbach[7], palaeoclimatic records of the past several thousand years thus seem most relevant to study of the natural variability of our present climate, and fall within the scope of current planning. The kinds of natural variations we can expect in the near future will very probably be similar to those experienced in the relatively recent past.

Tree rings as climatic proxy data

Within this time framework, the annual rings of trees are one of the most valuable sources of climatic proxy data. Trees are found in most land areas of the Earth, they can reach ages of several hundred to a few thousand years, and under favourable circumstances their growth rings can be dated to the exact year of formation. Dendrochronology can provide long, continuous sequences of accurately dated annual rings, and is a dating tool that has found applications in fields ranging from archaeology to vulcanology. More important here is the potential for detailed palaeoclimatic reconstructions, because the physical and chemical properties of the annual rings can yield records of a broad range of environmental variables that are directly or indirectly linked to climate. Tree rings combine environmental 'sensitivity' and great length of record with the potential for resolution to individual calendar years, or indeed, to individual seasons. Thus, tree-ring-based proxy data series bridge the critical gap between the longer but more generalised geological records of climate, and the shorter and more detailed records of instrumental observations of climatic, geophysical, geochemical and astronomical variables that are critical to understanding the causes of climatic variability and change.

Dendroclimatology, concerned with the reconstruction of past climates through study of the properties of tree rings, has developed rapidly within the past 15 yr. Major factors have been the greatly increased speed of data processing possible using modern computers together with the development and application of powerful multivariate statistical techniques, greater understanding of the biological processes linking climate and tree growth, and the expansion of applications to broad new geographical areas. Exciting results are beginning to emerge from the use of a variety of new methods now being developed for investigation of the physical and chemical properties of the wood itself, such as stable isotopic composition[8-14], density[15,16] and amino acid composition[17]. However, although a large body of understanding and expertise has evolved for dealing with the climatic interpretation of ring-width variability, more recent techniques based on physicochemical properties of tree rings are still in their infancy. Moreover, study of the traditional dendroclimatic variable—the width of the annual ring—has yielded a large body of palaeoclimatic data that serves to illustrate the range of possible applications, the nature of long climatic proxy series, and the implications of past climatic variability for the future.

Fig. 3 Streamflow reconstruction. Tree-ring records from semi-arid sites in the Neuquén River basin in Argentina were incorporated in a canonical regression analysis[35] to estimate annual runoff at Paso de los Indios for the calibration period of gauging station record (above) and for the entire period 1600–1967 (below). Trees and drainage basins integrate fluctuations in temperature and precipitation in similar fashion, as shown by the good correspondence of decadal average values, and a correlation coefficient of 0.73 between measured and estimated annual values.



Ring-width variability

Many of the biological insights, recent technical developments, and palaeoclimatic applications of ring-width data have come through the work of H. C. Fritts and his associates at this laboratory. His book[18] gives a thorough review of the field, develops a methodology, and illustrates its use, primarily through examples from western North America. A good, botanically orientated review of tree rings as a natural data storage system has been published[19] in Great Britain with a lengthy bibliography, and the potential for application of dendroclimatology there is illustrated by recent findings[20-22]. There is also renewed interest in climatic and other applications of tree rings elsewhere in Europe[23,24] and in eastern North America[25], and a major effort is underway in the temperate latitude Southern Hemisphere[26], including Australia[27] and New Zealand[28].

The basic premise underlying the interpretation of ring-width variations in climatic terms is that climatic factors can directly or indirectly limit growth processes in trees[18]. The most suitable trees (with climatically 'sensitive' ring series) are often found in marginal situations, such as at the northern treeline, at the upper treeline in the mountains of temperate latitudes, near the arid forest border in desert regions, or as suppressed understory trees in temperate rain forests. Under such circumstances, in an adverse year, one or more environmental factors, such as soil moisture content, air temperature, or sunlight may frequently limit biological processes such as photosynthesis that are essential for development of an annual ring of normal width. Because all the trees in the same area experience the same general weather conditions, all those in appropriate ecological situations will form a narrower-than-usual ring in a bad year. The resulting synchronous sequences of wide and narrow rings provide the basis for cross-dating of tree-ring series (Fig. 1) as well as for palaeoclimatic inferences.

Data collection

A variety of approaches can be followed in extracting climatic proxy information from tree rings. A general procedure is first to select field collection areas and to identify suitable species, and then obtain tree-ring samples in the form of increment cores and cross-sections. Experience indicates that samples for ring-width analysis should include cores from 10 to 30 trees on each geographically limited and ecologically homogeneous site. After sample preparation, cross-dating of the tree-ring series (Fig. 1) leads to development of a site chronology, ensuring accurate dating of the annual rings. Measurement of ring-widths of selected samples follows. Transformations are then applied to individual radial series of ring-width measurements to remove biological trends. The next step is internal evaluation of the dendroclimatic potential of the site, based on the degree of common variation of tree-ring properties through time. Results of cross-correlation tests and analysis of variance, for example, indicate the degree of correlation between radii on the same tree, and between trees on the same site, and are measures of the

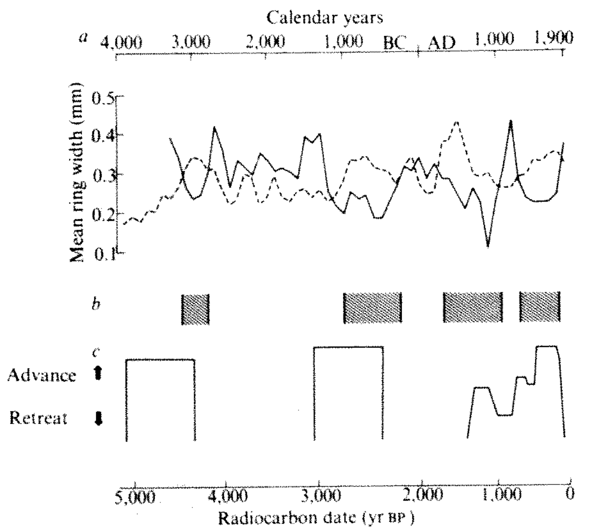


Fig. 4 Long-term fluctuations in temperature and precipitation. Although not explicitly calibrated in terms of climatic parameters, records from bristlecone pine in the White Mountains, California, offer strong evidence for changes in climate spanning centuries to millennia. (*a*), Successive 100-yr means of the average annual ring-width in large samples of trees from two ecologically distinct habitats, with quite different ring growth responses to climate. ——, Upper treeline (temperature-sensitive); ······, lower forest border (drought-sensitive). Inferred periods of relatively cool and moist climate in the White Mountains (*b*) agree well with evidence (*c*) of periods of growth and extension of mountain glaciers, mainly in western North America and northern Europe. Preliminary data for the lower forest border from C. W. Ferguson (personal communication); upper treeline curve from ref. 36; Holocene glacial fluctuations from ref. 37.

common climatic signal present in the data. Finally, a mean value function is computed by averaging annual values of ring-width indices to produce the final index chronology for the site.

The kind and amount of climatic 'information' contained in a tree-ring data series for a particular site can be established by comparison with nearby weather records. Multivariate techniques have been used to develop a transfer function (response function) relating departures of total weekly, monthly, or seasonal precipitation and mean temperature to departures in the tree-ring variable of interest[29]. The weather data may be from individual station records or may represent regional averages. The nature of the response function will, to some extent, determine the kinds of palaeoclimatic reconstruction that can be attempted using a particular tree-ring data series or set of series. It should be emphasised, however, that a diversity in response functions for tree-ring data from a given region is often of real advantage for palaeoclimatic inference. This kind of diversity stems from differences in response between species, and between trees of the same species in different habitats. Thus, an effort is made to maximise the information contained in a regional tree-ring data array by sampling trees on sites representing a range of altitudes and microclimatic situations, and to develop tree-ring chronologies for trees of different species in the same areas. Possible differences in the trees' response, both to different climatic variables and to the same variables in different seasons of the year, can be tested by multivariate response function techniques. The results help in determining the kind of approach to be used in palaeoclimatic reconstruction.

Palaeoclimatic reconstruction

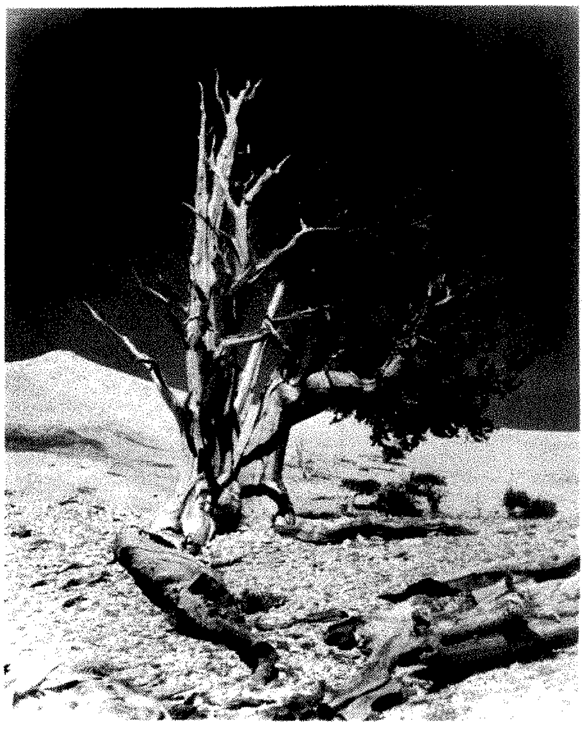
Several kinds of palaeoclimatic indices can be derived from tree-ring data. The kinds of climatic variables analysed, the spatial scale of the analysis, the degree of resolution in space and time, and the accuracy of the reconstruction or estimation will depend mainly on the inherent properties of the tree rings available for study and on the location of the trees. The proximity, quality and length of the available climatic records may also place some constraints on the scope of analysis. The quality of the proxy climatic records obtained from tree-ring data is probably best illustrated by examples of recent (and in some cases, preliminary) findings that range from estimates of a single variable at one point, based on a single tree-ring chronology, to the reconstruction of large-scale spatial anomaly patterns of several climatic parameters derived from analysis of data from a large network of tree-ring stations.

The simplest approach to palaeoclimatic reconstruction with tree-ring data is to use a highly stratified sample from trees responding (to a first approximation) in a simple manner to a single dominant climatic variable, such as precipitation. In this way, one can estimate past precipitation amounts at a point, along a meridional or zonal transect, or over a region. This kind of application is illustrated by a series of estimated annual precipitation amounts since AD 1010 for Santiago, Chile (Fig. 2). Inspection of this proxy record suggests that long periods of above- or below-average rainfall have occurred in the historically recent past, but are not well represented in the brief observational record. The ultimate extension of the single-variable approach is to use a regional array of tree-ring data points to infer past spatial anomalies in some dominant climatic parameter. This has been done successfully for precipitation[31,32] and for temperature[33] in the western US.

Complex, as well as simple, climatic variables can be reconstructed from tree-ring data. For example, stream runoff is often found to be positively related to precipitation, but negatively related to temperature, because warmer-than-usual conditions increase evapotranspirative water losses within the drainage basin. High temperatures can also limit growth processes in drought-sensitive trees directly as well as through depletion of soil moisture. Thus, tree-ring records can yield good proxy records of streamflow[34] as illustrated in Fig. 3, which shows large long-term fluctuations in flow from a major river basin in Argentina.

Past records of two variables can also be inferred at a single point, yielding information of great value for synoptic scale diagnostic analysis[36]. This is illustrated by comparison of very long records from bristlecone pine (*Pinus longaeva*) in the White Mountains of California (Fig. 4). In their lower altitudinal range,

Fig. 5 Biological impact of climatic variability. Bristlecone pines at upper treeline in the White Mountains of California are sensitive to fluctuations in warm-season temperatures. In a cool period (AD 1300–1850) coincident with Europe's historic 'Little Ice Age', the average growth rate dropped to half its former value (Fig. 4) and many trees succumbed to adverse growing conditions[38], leaving the trunks littering the foreground.



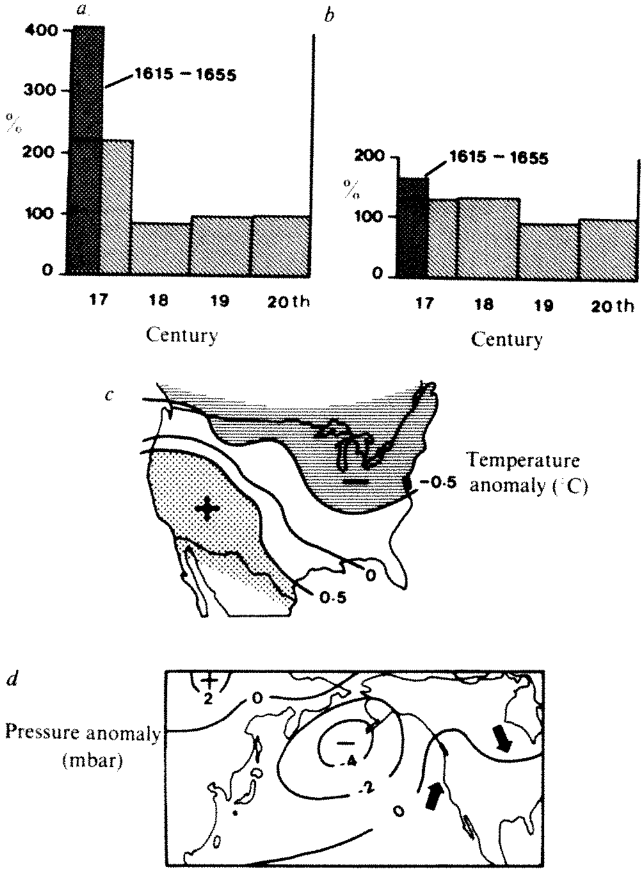


Fig. 6 Past climatic anomalies. Data from a grid of tree-ring sites in western North America have been used to reconstruct surface pressure anomaly patterns over the subhemisphere centred on the North Pacific Ocean for each season of each year, 1602–1962. Correlation analysis permits identification of the past occurrence of winters with pressure anomaly patterns like those of 1976–77 (*a*) and 1977–78 (*b*) over the past four centuries. Their apparent frequencies (above) are expressed as a percentage of their frequency in the twentieth century. Winters like these were especially common in the period 1615–1655. Reconstructed temperature (*c*) and pressure anomaly patterns (*d*) (based on 1901–1970 normal period) are shown below. Arrows indicate anomalous flow directions, bringing cold air to eastern North America. Adapted from Fritts and Lofgren[40].

ring-width is limited by drought conditions, especially low precipitation, whereas at upper treeline (Fig. 5) growth is mainly limited by low temperatures. Therefore, it is possible, by taking advantage of this diversity in climatic responses, to more fully characterise the nature of past climatic variations in this area. The warmth and humidity of the past century seem atypical in the light of the longer record.

Although ring-growth in trees can sometimes be approximated as a function of a single dominant climatic variable, a complex response to several environmental variables that are linked to climate is the more general case. Furthermore, the response to each variable, such as temperature, may change in magnitude or sign depending on the season of the year. For example, higher-than-usual temperatures in the previous autumn may be related to formation of a wider-than-usual ring in the current growing season, whereas high temperatures in the period immediately before and concurrent with the growing season may favour formation of a relatively narrow ring. Such relationships have been determined, and are readily interpretable in terms of the biological processes governing ring-growth[18]. Although comparatively little is yet known about the detailed relationships between climate and densitometric and isotopic variables, similar complex relationships are likely to be found in many cases[14].

Multivariate statistical methods have been successfuly applied to the simultaneous estimation or reconstruction of large scale spatial anomaly patterns of individual climatic variables, using tree-ring data representing a diversity of complex climatic response functions[29]. Techniques such as principal component analysis, stepwise multiple linear regression, and canonical regression analysis are used as tools for palaeoclimatic reconstruction on local to subhemispheric scales. Fritts *et al.* have been successful in using tree-ring data from western North America to estimate past sea-level pressure anomalies over a large area of the Northern Hemisphere[39]. In recent work, they evaluated the unusually cold (in the eastern US) winters of 1976–77 and 1977–78 in the perspective of several hundred years of proxy climatic record provided by tree rings. Their findings, shown in part in Fig. 6, strongly indicate that severe winters similar to these have occurred with great frequency at certain times in the relatively recent past. During part of Europe's historic 'Little Ice Age', the period 1615–1655, 70% of the winters seem to have been characterised by circulation patterns and associated temperatures over North America similar to those of one or the other of the past two winters.

Future directions

The future directions of dendroclimatic research will undoubtedly be strongly influenced by the needs of the climatological research community for specific kinds of proxy data in particular geographical areas. Nonetheless, present trends should lead to further expansion of the geographical data base, increasing contributions of new kinds of palaeoclimatic information from physicochemical analyses, and more intensive investigation of the time-series properties of tree-ring and derived data. The need to improve our ability to anticipate or predict future climate may result in the greater use of dendroclimatic data for actuarial-type analyses of the probability of future recurrence of past climatic episodes, and perhaps even for empirical forecasting.

Mechanisms and models of climatic change

G. J. Shutts & J. S. A. Green
Department of Physics, Imperial College, Exhibition Road, London SW7, UK

Many theories about climate change are essentially untestable, but we can still develop a consistent model based on understandable physics—in fact the data cannot be interpreted without one. Shutts and Green believe that there is some fundamental defect in all present models: it could be something physically improbable, like an unreasonable effect of tiny solar variations. More likely there is a fundamental lack in our appreciation of how very interactive systems behave.

CLIMATE modellers, in attempting to understand climatic an infinite number of mathematical models of physical processes and feedback mechanisms which are believed to be important. Economy of representation is achieved by the parameterisation of many physical processes. For instance, nearly all current models have avoided solving the equations for radiative energy transfer through the atmosphere and have made do with simple empirical schemes. Even though the theory of radiative transfer in the atmosphere is well known, its computation is tedious and parameterisation is simple and effective. Such an approach assumed that an assemblage of empirical processes (each one realistic in isolation) will behave like the real atmosphere, which has an infinite number of degrees of freedom and connections between processes. The art of parameterisation requires a blending of theoretical understanding, observation and physical intuition to achieve this and is a necessary part of modelling most, but especially very complicated, physical systems.

Definitions of climate

Is any useful purpose served by trying to invent a universal definition of climate? From a philosophical point of view, a definition in physics has little value outside the context of a mathematical theory. For example, the concept of heat becomes hopelessly ambiguous and devoid of use without the first law of thermodynamics, even though it retains its intuitive association with fire and physical sensation. Synoptic meteorologists go to some lengths to define 'blocking': a condition observed on maps of pressure patterns intimately related to anomalous weather conditions. Such people are unanimous in their diagnosis of a 'blocking situation' but are hard pressed to agree on a definition.

Over 20,000 years ago, nearly half the Earth was covered with ice to a depth of 1 km. There was a time a few hundred years ago when 'Frost Fairs' used to be held on the Thames River in London, and North West Europe suffered a drought between 1975–76. This is sufficient information to convey the subjective idea of climate change.

Climate is conventionally regarded as the state of the atmosphere averaged over an appropriate interval of time. If we believe that the climate changes in response to changes in 'external' processes, then the time interval can be chosen so that they vary little over its duration. By external processes we would certainly include variations of the intensity of solar radiation, the orography and perhaps also the state of the deep ocean and cryosphere. These definitions imply that the atmosphere is in a state of near-statistical equilibrium and responds to slow changes in the external factors.

The concept of quasi-static changes is a familiar feature of thermodynamics, and it is not surprising that many of the methods of statistical physics are 'borrowed' by the climatologist. Climate is sometimes thought of as an average over a hypothetical ensemble of atmospheric states that are in equilibrium with the slowly changing external factors. But, for instance, if the atmosphere always existed in one of two radically different states (glacial and non-glacial perhaps) this definition would hardly be appropriate. It would be much more useful to describe such a climate as the probability of the two states.

But what if climate changes are completely 'internal' and occur with fixed solar radiation, orography and ocean state (that is, are merely internal 'thermodynamic' fluctuations)? Choice of an averaging time interval is then more arbitrary, but at least should be sufficiently long to filter out 'weather' fluctuations. Definition of climate and its subdivision from medium-range weather should be left to the philosophers.

Hypotheses of climate change

Before launching into an account of the possible causes of climatic change, we will briefly describe the principle aspects of the general circulation of the atmosphere and its cause.

The atmosphere behaves as a heat engine in response to its nonuniform absorption of energy radiated from the Sun. The resulting spatial variation of internal and gravitational potential energy is converted into kinetic energy of air motion by processes such as ordinary convection. The distribution and intensity of solar radiation is controlled primarily by the geometry of the Earth and its orbit. Much of the incident radiation (about 30%) is reflected back to space by clouds, ice and the type of land surface. The atmosphere is quite transparent to this short wavelength solar radiation, with most of the energy occurring in the visible part of the spectrum. Energy balance is achieved by terrestrial re-radiation (at infrared wavelengths) to space from the uppermost 'optically black' layers of water vapour and carbon dioxide. The outgoing infrared radiation is of much smaller spatial variation than the incoming solar beam with the result that low latitudes receive a surplus of energy and middle and high latitudes a deficit. Balance of the integrated infrared radiation with the incoming solar (depleted by reflection mainly from clouds) determines the overall average temperature of the atmosphere—presently about 250 K. Vertical convection in the form of clouds transfers energy upwards from the ground to the high troposphere (about 12 km) and determines the vertical structure of temperature. It remains to transfer heat from equatorial to polar regions, and it is this process that determines the overall temperature variations at the surface. It turns out that the travelling depressions and anticyclones, characteristic of

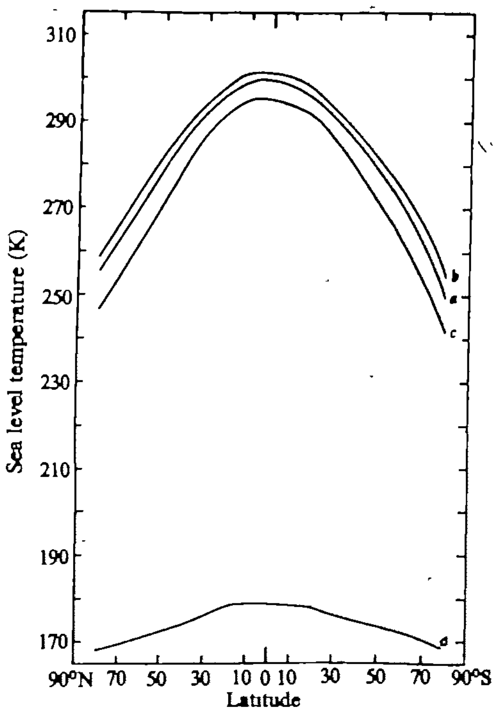

Fig. 1 Steady-state temperature distributions for various values of solar input and parameterisation[33] showing the calculated extreme sensitivity of surface temperature to small variations in solar input. Global mean temperature (K): *a*, 287.06, *b*, 289.81, *c*, 281.22; *d*, 174.65. Solar input. *a*, no change; *b*, +1%; *c*, −1%; *d*, <1.6%

unsettled weather, are the primary agency for transporting heat polewards in the atmosphere. These large scale eddies are dominated by effects due to the Earth's rotation and tend to redistribute angular momentum, causing the predominance of surface westerlies in middle latitudes, and easterlies elsewhere. These wind belts in turn determine the climatic belts of the planet.

Mountain ranges and heat anomalies, like warm winter oceans, tend to obstruct the circulating air, thereby creating stationary wave motion. The resulting nearly steady motion accounts for much of the zonal asymmetry of the climate. The Asiatic winter anticyclone and summer monsoonal low pressure are two outstanding examples of this type of local climatic variation.

(1) Solar energy output changes: The most obvious hypothesis for climate change attributes fluctuations in the global mean temperature to variations in the energy output of the Sun. Observations only in the past few decades have barely been able to detect changes in the solar irradiance of the order of 0.1% over 27 days. Several investigators[1,2] have correlated periods of high solar activity (indicated by the presence of sunspots) with anomalous tropospheric weather events such as 'blocking' or thunderstorm frequency.

The infamous 11-year sunspot cycle has been found to be astonishingly well correlated with a variety of atmospheric parameters (for example, hot summers, rainfall, lightning frequency) but in the absence of a plausible physical theory to account for them, scepticism remains.

(2) Orbital changes affecting solar insolation: Palaeoclimatological records for the last million years (the Pleistocene period) and particularly estimates of the global ice volume changes by analysis of the isotopic oxygen content of fossil plankton, indicate a strong periodicity of 100,000 years. Milankovitch[3] proposed that the secular variations of the Earth's orbit about the Sun would be sufficient to give fluctuations in the solar constant of a few per cent.

These orbital changes are due to changes in (i) the eccentricity of the orbit with a period of 96,000 yr; (ii) the obliquity of the Earth's axis with a period of 40,000 yr; (iii) the Earth's tilt by precession, with a period of 26,000 yr; and (iv) the orientation of the elliptical orbit which rotates with a period of 96,000 yr.

Mason[4] agrees that the period and magnitude of these orbital changes lead to solar energy fluctuations which can explain parameters of the palaeoclimatological record, such as global ice volume change.

(3) Greenhouse effect—modification by CO_2: Global increases in the amount of CO_2 in the atmosphere through the burning of fossil fuels are thought to be important enough to influence the greenhouse effect (the process by which infrared radiation is trapped by CO_2 and water vapour leading to surface temperatures higher than the black body temperature). Although the direct effect of an increase in CO_2 may be quite small (surface temperature rises of about 2 K if the amount of CO_2 is doubled), it is difficult to estimate how the rest of the system will react. For instance, a small global temperature increase with the addition of CO_2 will increase the moisture holding capacity of the air. Water vapour is the most important constituent involved in the greenhouse effect and so the net increase in temperature could be much greater than that predicted on the basis of CO_2 alone.

(4) Volcanic dust: The presence of volcanic dust in the upper atmosphere has been put forward as a way of increasing the albedo and thus reducing the mean atmospheric temperatures. Hunt[5] has investigated such influences with a three-dimensional general circulation model and has found a mean surface temperature reduction of at most 1 K. He concludes that volcanic eruptions could have a significant effect on the atmosphere, though lasting changes are improbable.

(5) Ice cap/albedo positive feedback: Climatology literature abounds with possible positive feedback mechanisms which could render the climate unstable. Of these, the polar ice cap/albedo feedback is the most popular. The argument is quite simple. An increase in the horizontal extent of the polar ice sheet increases the global albedo, which in turn results in lower temperatures through the reduction in absorbed solar radiation. Colder surface conditions encourage the expansion of the ice sheet and so on. Budyko[6] and Sellers[7] have investigated the equilibrium mathematical solutions of simple zonally averaged heat balance models which have ice sheet dependent albedo variation and include a diffusive poleward transfer of heat. Their calculations show that a decrease in the solar irradiance of 2–5% would be sufficient to initiate another ice age.

(6) Oceanic influences: Weyl[8] has presented a case for the initiation of Ice Ages by reduction of the salinity of the North Atlantic Ocean. He claims that the 'Little Ice Age' of AD 1500–1850 substantiates his hypothesis. Certainly on a time scale of years or tens of years the ocean surface temperatures are believed to exert a strong influence on weather types. Namias[9] believes that the evolution of monthly mean weather is largely controlled by the oceanic temperature anomalies.

(7) Other topographical influences: Changes in the condition of the Earth's land surface by mountain building and vegetation growth or decay are amongst other possible climate change mechanisms. Charney[10] has described a positive feedback mechanism which causes desert conditions through overgrazing: reduction of plant cover increases the albedo which, in turn, causes a greater radiative deficit. The resulting horizontal temperature gradients induce subsidence which inhibits convective precipitation and therefore curbs plant growth.

Methods of climate modelling

It is possible to divide climate models into three broad categories: (1) energy balance models that include radiation/albedo feedback processes but contain no explicit dynamics; (2) low resolution statistical–dynamical models that include large scale eddy transports of heat and momentum in parametric form, for example, as some curious variety of conductivity; and (3) simulation models of very high resolution that include all motion on scales greater than some 100–200 km.

(1) The energy balance models can be used to explore the sensitivity of zonally averaged climatic states that are determined by the ice-cover/albedo feedback mechanism (see Fig. 1).

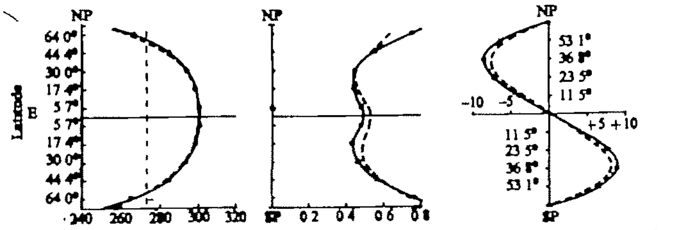

Fig. 2 Taken from Paltridge[12]. ——, Predicted; ----, observed

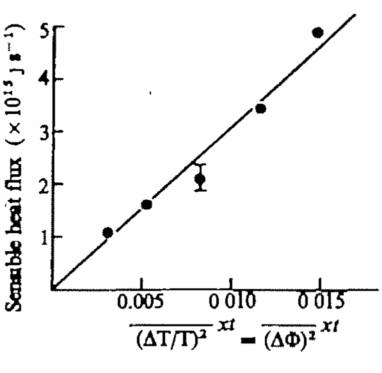
They show that small changes in the solar input can cause catastrophic changes in the surface temperature of the model. Using a time-dependent model, Schneider and Gal-Chen[11] have found that a reduction in the intensity of solar radiation by more than 1.6% results in a fall of global mean temperature of over 100 K. As with all climate models, it is difficult to believe that such large excursions from present conditions are adequately represented by the processes, the parameterisation of which depends on the current state of the atmosphere.

A unique approach was adopted by Paltridge[12] who sought a minimal principle governing the zonally averaged distribution of cloud cover, surface temperature and poleward heat transport. The incident solar radiation at the top of the atmosphere was the only externally prescribed quantity. By minimising the rate of generation of entropy, very close agreement of the fundamental model unknowns with observation was found (Fig. 2). No dynamical information was required in the model—a disturbing fact when so much effort is devoted to integrating the equations of fluid motion. Further work by Paltridge[13] has led to predictions of the global cloud cover and rainfall, again with surprising accuracy.

The notion that the climate does not depend on the Earth's rotation seems hard to accept, yet the agreement with observation is striking. The philosophy of such an approach is very appealing, and is in line with the idea of applying thermodynamic concepts to the climatic problem. Indeed, the principle of minimum rate of generation of entropy is well established in the field of non-equilibrium thermodynamics for a certain class of physical processes[14].

(2) These models are primarily concerned with the main global features of the time-averaged wind and temperature fields without explicitly describing the transient depressions and anticyclones or any other smaller scale of motion. The statistical effect of these smaller scales of motion is parameterised in terms of the larger scale fields which are described explicitly. One such 'prescription' for the turbulent transfers of heat and momentum accomplished by large scale eddies was given by Green[15]. Some aspects of this parameterisation seem to describe global-scale transports realistically (Fig. 3). The parametric formulation of the eddy transport of angular momentum is not so realistic and remains one of the most important and difficult aspects of our understanding which is highlighted in these models.

Fig. 3 Eddy flux of sensible heat across 50°N plotted against $\overline{(\Delta T/T)}^{2*}$, $(\Delta T/T)$ = fractional temperature difference between 20 and 70°N, 500 mb (from Green[15])



(3) The general circulation models of this category are widely used for climatic studies. They are essentially similar to the models used for weather prediction and seek to embrace as many relevant physical processes with as much resolution as is computationally feasible. In contrast to the previous type, these models extend their explicit representation to that of weather patterns, even though in their weather forecasting capacity they have predictive value for only a few days. In the most advanced models, the circulation of the oceans is also modelled, though integrated with a much longer time step to that of the atmospheric circulation.

Uses and abuses of models

The Budyko–Sellers models are useful for assessment of sensitivity: most of the estimates of the effect that changes in CO_2 or solar irradiance might have are based on them. Unfortunately, there is only the insufficient climate record against which they might be tested. This is true of most models and has the corollary: "any fool can make climate predictions because he won't be there when it's time to collect the bad debts."

The Paltridge model apparently gives excellent results, but no-one understands the physics that goes into its construction. Furthermore, it has only been tested against the present climate of the Earth, and might, therefore, be just a one-off success. Highly parameterised models can reproduce some results of more complex models (though not as well as that of Paltridge) but so far are generally considered to be an outside chance in view of their palpable over-simplification. General circulation models (GCMs) have been extensively used (The UK Meteorological Office spends about as much on running their model as goes into university education of meteorologists in Britain.) Much is known about their behaviour which is not known about other models. The nature of these characteristics may form a guide to those of other models.

All models are much more similar to each other than they are to the real atmosphere—it's easier to forecast the weather forecast than the weather. Details are consistently wrong in all models.

Although the predicted values for the poleward transport of energy and momentum are surprisingly accurate (they are closer to the long-term mean than the year-to-year variability of atmospheric transfers), the calculated intensity of the eddy motion is much less than observed.

Earlier versions demanded some judicious manipulation of parameters in order to reproduce the present climate. That this is said not to be true of later models may indicate greater skill in anticipating the required numbers or greater understanding of the relevant physical processes. How can we tell?

All GCMs produce westerly jet streams that extend much too far into the upper atmosphere. A detail, but it goes with not having the polar stratosphere warm enough by some considerable amount. It is worrying that this type of defect is tangible and universal in a region where we 'know all the physics'.

No climatic model has actually predicted a climatic anomaly or has been able to simulate one for which there was sufficient meteorological data to make it a proposition in numerical analysis. We believe that this applies, for example, to the anomalous North American winter of 1977–78, and to the British drought of 1975–76.

Finally, these models suggest that climate is essentially unpredictable: that we can only predict in the probability sense of many 'realisations' (or re-runs from 'nearly-the-same' initial data). Is it the climate model or climate that is unpredictable? We must stress that these conclusions are biased and arguable. Some are demonstrably true of general circulation models, but we believe many are symptoms of the climate problem.

Numerical simulation of climate and climatic change

A. Gilchrist

Meteorological Office, London Road, Bracknell, Berks, UK

Detailed three-dimensional numerical models of the atmosphere, coupled as necessary to models of other parts of the climatic system, provide the most promising approach to understanding the physical basis of climate. Models of this kind can be used to investigate the impact of anthropogenic pollution on climate. At the present time, the main concern is with increasing concentrations of CO_2 which might lead to overall warming of the troposphere, but chemical and thermal pollution may also pose a threat. The possible climatic changes would take place slowly and would involve the response of the slowly reacting parts of the climatic system, particularly the oceans. The problem of how to simulate such changes of climate presents many difficulties, which are currently being studied.

THE most powerful tool available for studying the physical basis of climate and climatic change is the general circulation model, which simulates the evolution of the atmosphere numerically and is capable in principle of taking into account all the factors that determine climate. Such models are complex and require a range of expertise and prolonged experimentation to bring them to the point where they can be put to good use in climate experiments that are of value. Consequently, their development has been undertaken at only a few centres. At a recent conference in Washington (April, 1978) organised by the Joint Organising Committee for the Global Atmospheric Research Programme for the purpose of comparing climatic simulations, results were presented from nine institutions. Of these, four were from the USA, two from the Soviet Union, with one from Australia, Canada and the UK. However, some of the models described were at a preliminary stage of development and only the American and UK Meteorological Office groups have tested models extensively in studies of climate.

Fundamental physical equations

The starting point for general circulation models are the fundamental physical equations for the rates of change of the components of velocity, temperature and humidity at a point in the atmosphere. The equations include a description of the processes by which the atmosphere interacts with radiation (infrared and solar) and the underlying surface of the Earth. They are solved on a network of points over the globe to provide a continuing evolution of atmospheric states. Processes that take place on too small a scale in the real atmosphere to be represented explicitly are 'parameterised' in terms of the variables available on the mesh; for example, the vertical transfer of heat and moisture due to buoyancy forces which in the real atmosphere produce cumulus clouds and showers is treated in this way.

Conditions that are external to the atmospheric dynamical system are specified. These include the constituents of the atmosphere, the radiation conditions, defining either explicitly or implicitly the Sun's position with respect to the Earth, and the characteristics of the Earth's surface that influence its interaction with the atmosphere and radiation. For a land point, the latter would include the height above mean sea level, the albedo without snow cover and the change due to snowfall, the roughness, and a heat capacity to define how its temperature would respond to the absorption of heat.

For a sea point a purely atmospheric model lacking a dynamical interaction with the ocean requires either the sea-surface temperatures to be specified or to be determinable from the local heat balance. The former, with the values set to the long-term climatological average, is appropriate when the object is to provide a realistic simulation of climate, and the latter has been used in attempts to understand particular features of the atmosphere's general circulation where the use of temperatures that are themselves partly determined by the atmospheric circulation is inappropriate. Combined ocean–atmosphere models which allow a dynamical evolution in both fluids are now being constructed and tested[1], as for many processes of interest in climate an interactive system is essential.

General circulation models

These provide in principle, and already to some extent in practice, a method of estimating the global climate for any set of prescribed 'external' conditions. To do so, they have to be integrated through an extended period of simulated time during which many atmospheric states are created. The length of integration needed may well depend on the precise problem being considered. It should be long enough for a statistical equilibrium to be established between the atmosphere and the prescribed conditions and, ideally, it should include a sufficiently varied range of atmospheric states to make it possible to estimate the probability of occurrence of any particular state with these conditions.

Given this information, the more usual characteristics that are taken to define climate may then be derived; these are the long-term averages, the extremes, the year-to-year variability, and so on. For most problems involving a change of climate, it would probably be more convenient to estimate the climate, not in absolute terms, but with reference to what is now observed. This is an easier goal, and as minor deficiencies revealed by model estimates of the present climate can probably be allowed for, the end-results may be achieved with rather simpler models.

Models are still in a comparatively early stage of development and up to the present attention has for the most part been concentrated on their ability to simulate the average conditions. For example, a number of simulations of the present climate have been described in the literature[1,3–6], and there have been attempts to simulate the climate of the last ice-age by using data from the CLIMAP project[7] to define the extent of glaciation and the sea-surface temperatures 18,000 yr ago. In general terms the

0028–0836/78/0276—0342$01 00

models achieve a simulation of present climate that contains all the major features of the atmospheric circulation, but there are systematic errors in the intensity of some of them that call for further development and improvement.

The importance of this aim has been recognised by the international community which has supported international experiments such as GATE (the GARP Atlantic Tropical Experiment) in 1974 and FGGE (the First GARP Global Experiment) in 1978–79, the main purpose of which has been to obtain the data required to test and systematically improve the simulations. An important aspect of the FGGE is that data will be collected from a complete yearly cycle, enabling the models to be tested in a wide variety of conditions. Remembering that within the annual cycle there is a greater range of climates than have affected any particular part of the year at least in the last millenium, it is obvious that the potential of the FGGE to improve climatic modelling, provided a sufficiently comprehensive coverage of observations is obtained, is substantial.

The ice-age simulations[8–10] were obtained using similar methods to those applied to present-day climatology. Maintaining the sea-surface temperatures, the distribution of ice and the solar parameters at their 18,000 yr BP values, the general circulation models were integrated long enough for the atmospheric motions to come into statistical equilibrium with the boundary conditions. There are significant differences in the simulations, and because of a number of inadequacies the results must be considered indicative rather than definitive. Nevertheless, they are of interest in suggesting certain aspects of the ice-age climate that can be checked against geological evidence. Thus, the GFDL integration[8] favours comparative dryness in the ice-age tropics and this is considered to be supported by evidence provided by the sand-dune distribution of 18,000 yr BP. The model integrations agree in having generally less rain and lower global temperatures during the ice-age than now.

Why numerical models?

It is evident that although general circulation models are a very powerful tool for investigating the physical basis of climate and climatic change, they involve a lot of computing, and therefore it is tempting to enquire whether there might not be a simpler method which could be equally successful. There are, however, good reasons why large numerical models occupy a central position in studies of climate. The first stems from the fact that controlled experiments cannot be carried out on the atmosphere, at least not on anything approaching a global scale. In these circumstances, large numerical models provide the only feasible method of testing hypotheses. Without them research in climate can easily become (and indeed for a long time was) a series of uncheckable speculations. This is not to imply that the results of a particular model are correct; but it is an inherent property that they provide not simply an initial cause and a subsequent effect, but a chain of consequences linking the two. Taken individually, the links in the chain are usually of such a kind that they can be checked quantitatively against atmospheric observations; in particular, critical links can be identified. Another reason is that it has become clear that climate is determined by complex interactions among a number of systems, these being the atmosphere, the oceans, glaciers, the Earth's surface, and so on. Indeed, the essence of the problem of climate which distinguishes it from, for example, problems in atmospheric dynamics, is that interactions between the atmosphere and other systems are involved. The processes occurring within the systems are themselves often exceedingly complex; to rationalise and explain the interactions between them is generally speaking beyond the expertise of any one individual and can involve so many factors whose importance cannot be ruled out *ab initio* that the only possible approach is to try to incorporate them in a model that can be solved numerically.

These points can be illustrated from the work of Charney[11] in trying to explain the severe drought in the Sahel in 1972. The range of possible interactions that might have created the drought is very large, and they cannot be subjected to precise experiments; it may therefore be very misleading to choose certain of them as dominant without quantitative modelling of all the potentially important factors. In the first instance Charney[11] sought to explain the Sahel drought by a biogeophysical feedback mechanism. He postulated that a reduction of vegetation in a borderline desert region had occurred, possibly due to lack of rain or to heavy cropping by animals. A greater amount of light soil would therefore be exposed and the increase in the albedo would lead to a greater proportion of the incoming solar radiation being reflected back to space. Less heat would therefore be available to heat the atmosphere. If temperatures further from the desert remained unchanged, a more intense circulation with downward motion over the area of increased albedo would tend to be produced, and so reduce the rainfall and the vegetation cover even further. Charney proposed that this could account for the prolonged drought in the Sahel.

The hypothesis was later tested in experiments with a general circulation model[12]. In this case the situation was shown to be much more complex than the original explanation allowed for. Thus, it was found that, as expected, a larger albedo reduced the proportion of the incoming solar radiation absorbed at the surface, but because it also reduced the input of heat and moisture to the lower atmosphere there was less cloud. More solar radiation therefore, reached the ground, and in some experiments the absorption of solar radiation at the Earth's surface actually increased. However, with reduced cloudiness there was less infrared radiation back to the surface, with the result that the net absorption of radiation was less. The proportions that went into evaporation and into sensible heating of the atmosphere depended on the wetness of the surface; in the experiments this factor was fixed from climatological values, but in reality it depends on the rainfall, thus introducing another feedback mechanism that is potentially very important. In general, increasing the albedo led to a decrease in the precipitation, but this was not invariably the case. In experiments in which the evaporation was almost negligible and which therefore accorded most nearly with Charney's original conjectures, the results varied among the regions where the albedo was increased; the change seemed to increase precipitation in some areas and reduce it in others.

It is clear from Charney's experiments that the consequences of an increase in albedo are by no means easy to predict. An assessment of the physical processes involved requires rather precise quantitative modelling and a careful check against observations of all the interactions that seem to be important. From the point of view of explaining the Sahel drought the situation is even more complex, as there are factors other than the albedo that may be important. Thus, Walker and Rowntree[13] have shown that the soil moisture content can have a direct influence on atmospheric dynamical developments in desert fringe areas, and this factor was not represented effectively in Charney's experiments. Also, from studies of the effects of anomalous sea-surface temperatures on the atmosphere, carried out using the Meteorological Office general circulation model, there is some evidence that the droughts may be linked with abnormally cold water in the tropical Atlantic. If this is confirmed it might account for the longevity of some droughts in the Sahel, as there is considerable evidence of long period variations in tropical sea temperatures.

The processes that determine climate evidently involve delicate balances among physical systems which even in isolation are complex and not easily understood, and which cut across the boundaries between the individual expertise of scientists. The problems can only be solved as a result of effective cooperation between meteorologists, oceanographers, radiation experts, plant physiologists, and so on. General circulation models provide a means of integrating the contributions of each field of expertise to arrive at the total influence on climate.

Impact of man's activities

In considering climatic change due to natural causes, the existence of climatic data for the past, either as direct measurements or as proxy data derived from tree-rings, ice-cores or cores from ocean or lake sediments, provides at least a statistical account of the variations that are likely. When one turns to the possible impact of man's activities, there is little chance of finding a sufficiently close historical analogy, and it is difficult to envisage a systematic approach to estimating the effects quantitatively which does not depend essentially on simulating them by means of sufficiently comprehensive numerical models. At the present time, for example, the main concern arises from the increase in CO_2 concentrations in the atmosphere, thought to be due principally to the burning of fossil fuels. One-dimensional column models, which calculate the local temperature change in a still atmosphere due to varying concentrations of the radiatively active gases, indicate that, for typical conditions, increasing the concentration of CO_2 produces a warming of the troposphere and a cooling of the stratosphere and upper atmosphere.

There is now substantial agreement[14] among such models that the temperature change to be expected from a doubling of the amount of CO_2 from its present value of about 320 p.p.m. is about 2 K at the Earth's surface. This value includes a feedback from water vapour which accounts for about half the total increase. The CO_2 warms the lower atmosphere, which in consequence can hold more water vapour, and the absorption of radiation by the water vapour enhances the warming. The results depend on the conditions of cloudiness assumed, and in general no allowance is made for changes in cloudiness that might arise from the increased temperature and water vapour content.

A general circulation integration by Manabe and Wetherald[15] using a much simplified surface topography and ignoring the effects of ocean currents, the annual solar cycle and variations in cloudiness, has demonstrated additionally that in higher latitudes, where the warming reduces or removes highly reflecting snow-cover with its typical low level atmospheric inversion, the change in surface temperature could be much greater, perhaps up to about 10 K. They also found that the hydrological cycle was more intense because of the additional moisture-carrying capacity of the atmosphere, and it can be surmised from their paper that the distribution of rainfall was significantly altered. A statement approved by the Executive Committee of the World Meteorological Organisation[16] has called particular attention to the CO_2 problem, and has pointed out the urgency of defining its impact more precisely.

The immediate problems are, firstly, to forecast future concentrations of CO_2 and, secondly, to translate their effects into likely changes in climate. It is on the second problem that meteorological investigations must concentrate, although it has to be recognised that changes in climate may affect the storage of CO_2 in the oceans and in the biomass; therefore, the two aspects are not independent. The obvious first extension from present results is to try to obtain a clearer view of the regional changes, particularly of temperature and rainfall, that might be produced by increased amounts of CO_2. It is perhaps salutary to recall the results of a Meteorological Office experiment in which the Arctic was maintained ice-free[17]. This of course led in general to higher temperatures. Nevertheless, Britain and Western Europe were much colder because the predicted atmospheric flow patterns showed prevailing winds that were backed from their present direction towards a more easterly point. In a similar way, the effect of more CO_2 will probably vary from one part of the globe to another, some parts showing a cooling in spite of the global temperature being higher. There might also be significant changes in the probabilities of extreme events, such as the incidence of very cold winters or severe droughts in Britain, or of flooding of low-lying areas. It is important to try to identify these regional variations, with perhaps special emphasis on the rainfall changes which could easily have a substantial impact on agricultural productivity.

If present indications are correct, the effect of greater CO_2 concentrations will be felt increasingly over the next century or so. There will be a gradual change in the Earth's climate involving changes in the oceans, in sea-ice, in glaciers and in the vegetative cover of land surfaces as well as in the atmospheric motions. Just how radical the changes will be is uncertain at this stage. To produce a forecast of the evolution of the climate with time is a problem which may not be capable of solution in an exact sense, and for which indeed no clear methodology that would lead to a solution has yet been established. To create a model involving all the systems analogous to an atmospheric general circulation model and simulate their interactions comprehensively in a long-term integration, for example, is out of the question.

Estimates of future climate

There are, nevertheless, approaches that might be tried. It has already been emphasised that general circulation models provide a means of estimating the climate for a given set of 'external' conditions. We have to reckon with the fact, however, that few parts of the climatic system are truly external and independent of the atmosphere. Factors emanating from outside the Earth, such as solar radiation, factors emanating from below the Earth's surface, such as volcanic dust, and certain inputs by man himself, come into this category. There remains a complex of systems that interact with the atmosphere; some react quickly, whereas others change only slowly as a result of an atmospheric input.

The atmosphere itself is highly variable from day to day, and some aspects of the processes at the Earth's surface such as evaporation and the establishment or disappearance of temporary snow-cover are on a similar time scale. At the other end of the scale, glaciers and the deep ocean may require years of altered conditions to change significantly. From the point of view of establishing an estimate of climate that is essentially steady (apart from the annual cycle) over periods of years or decades, the very slowly responding systems can probably be considered as effectively external. A reasonable methodology for dealing with slow long sustained climatic change then emerges.

The first step would be to establish the statistical characteristics of a climate for a relevant set of 'external' conditions using a general circulation model that includes factors varying on short time scales. As well as the atmosphere and some land surface variations, this ought to include also the upper layers of the ocean, which react quickly to atmospheric changes. The existence of upwelling in the oceans by which in limited localities the deep waters can come fairly rapidly into contact with the atmosphere, might cause difficulties which would have to be overcome. The climate once established could then be allowed to act on the more slowly varying parts of the climatic system for as long a period as was deemed reasonable. For example, the gradual change in the ocean circulation and changes in glaciation could be calculated on the basis of a steady climate as long as the changes were not too large.

The assumption is essentially that for small changes the variations in the slowly responding systems are nearly linear. The extent to which this is so could of course be checked by preliminary experiments. Once significant changes had taken place it would be necessary to go back to the general circulation model to re-establish a relevant climatology. In this way it is at least methodologically possible to try to estimate the evolution of climate taking place over long periods of time.

The CO_2 problem is the most pressing at present, because there is enough generally accepted scientific evidence to indicate that the impact on climate could be substantial. Changes that might result from other human activities are less clearly understood, but there are obvious possibilities that they might become more important in the future. Thus, the input of waste heat into the atmosphere has significant effects locally, evident for example in the increase in temperature at some meteorological sites as a result of urbanisation nearby.

The future global energy position is far from clear, but if this involved the use of very large nuclear power stations, vast amounts of heat could be injected into the atmosphere in concentrated sources whose effects are as yet not well understood. An experiment using the Meteorological Office general circulation model, carried out in association with the International Insitute for Applied Systems Analysis, has shown that the input of 1.5×10^{14} W to a particular area had a large effect on the global climate and changed the pattern of air movement and rainfall very substantially. This amount is much greater than present world consumption (~ 7–8×10^{12} W); nevertheless, the response is such as to demonstrate that it would be prudent to investigate the possible impact on climate before large energy projects which might release large amounts of energy are embarked on.

The possibility that the ozone layer might be reduced by the injection of pollutants into the stratosphere has been much discussed in recent years, first in the context of supersonic aircraft flying in the stratosphere and more recently as a result of the accumulation of inert gases such as freons. The possible danger is firstly to living material because of the increased amounts of ultraviolet radiation reaching the ground, and secondly, in the longer term, to possible changes in climate that this would produce.

Some of the early fears about increased radiation were evidently exaggerated[19], and the mechanism by which changes in ozone would lead to noticeable changes in the climate is far from clear. Some experiments[20] in which the ozone was increased showed substantial warming at the ozone levels themselves but little impact at the Earth's surface. Should the possibilities for climatic change be shown to be more real than has so far been demonstrated it would be necessary to follow a methodology similar to that just outlined for CO_2 to make some estimate of the detailed effects over a long period.

Recent developments in atmospheric chemistry

B. A. Thrush
Department of Physical Chemistry, University of Cambridge, Lensfield Road, Cambridge, UK

The chemistry of the atmosphere was a largely neglected topic until the last decade during which concern about pollution has produced a flurry of activity. The processes which may deplete the relatively small amount of ozone in the stratosphere which protects us from harmful UV light have much in common with those in the Los Angeles-type smog which generate ozone and other oxidants. Such systems involve chain reactions in which free radicals such as HO, HO_2, ClO can carry out a chemical conversion process (ozone to oxygen) many times before they are destroyed. Recent research shows that nitrogen oxides from the exhausts of supersonic aircraft or derived from increased use of nitrogenous fertilisers will have little effect on stratospheric ozone but the potential effects of chlorine compounds, such as aerosol propellants, require careful examination. In contrast, the oxidation of carbon monoxide is now thought to be a major source of ozone in the lower atmosphere.

THE past decade has seen a tremendous growth in research on atmospheric chemistry; this has stemmed largely from the need to identify the processes which remove many of the compounds which man releases into the atmosphere on a large scale and to assess their potential effect on the environment. These problems highlighted our lack of knowledge of the concentrations of important trace species in the unperturbed atmosphere and of the processes which control them. Fortunately both atmospheric and laboratory measurements on these trace species have been greatly aided by recent developments in highly sensitive spectroscopic methods for measuring their concentrations, notably fluorescence, high resolution absorption spectroscopy and laser magnetic resonance.

Computer modelling provides an essential link between laboratory measurements of reaction rates of atmospheric species and the determination of their concentrations in the atmosphere, as the number of reactions is large and the atmospheric circulation a formidably complex problem. Because, in the lower and middle atmosphere, gases are transported by the movement of air masses rather than by molecular diffusion, it will be several years before the massive computational problem of combining a general circulation model of the whole atmosphere with an adequate description of the chemistry can be achieved. In most current work, the transport is parameterised in terms of an 'eddy transport coefficient' which has the same dimensions as a diffusion coefficient.

Two-dimensional models of the atmosphere in which altitude and latitude are variables are now replacing the one-dimensional models involving only altitude; these cannot, for instance, describe the transport of ozone from its predominant formation regime near the equator to the poles where its concentration is greatest.

Comparisons of the measured and calculated concentrations of trace species in the atmosphere provide the best test of the adequacy of our understanding of atmospheric chemistry and transport. Because the tropopause (the temperature minimum at an altitude of about 15 km) provides an effective barrier to transport between the dry, relatively stable stratosphere and the moist rapidly mixed troposphere below it, it is convenient to consider the chemistry of these regions separately (Fig. 1).

Stratospheric chemistry

Here the dominant interest is in the processes which control the small amount of ozone which protects the Earth's surface from ultraviolet light with wavelengths less than 300 nm; this corresponds to a 3-mm thick layer of pure ozone gas at ground level. The basic mechanism for the formation and removal of ozone was proposed by Chapman[1] in 1930. Molecular oxygen is dissociated by light with wavelengths less than 242 nm to form oxygen atoms. These combine rapidly with molecular oxygen to form ozone, a process which requires a third body (M) to remove excess energy

$$O_2 + h\nu(\lambda < 242\ \text{nm}) = O + O \qquad (1)$$

$$O + O_2 + M = O_3 + M \qquad (2)$$

Ozone is very rapidly photolysed by visible and ultraviolet light to regenerate oxygen atoms

$$O_3 + h\nu = O_2 + O \qquad (3)$$

It is also removed by reaction with atomic oxygen to regenerate molecular oxygen

$$O + O_3 = O_2 + O_2 \qquad (4)$$

There is a fundamental difference between these two decomposition processes for ozone. Process (3) followed by reaction (2) merely interconvert O and O_3 which are termed 'odd oxygen' species, whereas (4) converts the odd oxygen formed by process (1) back to (even) molecular oxygen. Although Chapman himself and others had clearly envisaged that other processes could destroy much atmospheric ozone, only in the present decade have laboratory and atmospheric measurements become accurate enough to establish that reaction (4) only accounts for about one-fifth of the odd oxygen destruction in the atmosphere[2].

The other mechanisms for ozone removal can most easily be envisaged in terms of catalytic cycles in which a species converts O and O_3 into O_2 without being destroyed itself

$$X + O_3 = XO + O_2 \qquad (5)$$

$$XO + O = X + O_2 \qquad (6)$$

$$O + O_3 = O_2 + O_2 \qquad (5)+(6)$$

For reactions (5) and (6) to be rapid, X needs to have an unpaired electron; the importance of atmospheric cycles with X = H, HO, NO and Cl have been recognised[3–6]. (The stability of HF in the atmosphere prevents F contributing to such cycles; there is insufficient bromine in the atmosphere for X = Br to be important.) The hydrogen radicals, H, HO and HO_2, which participate in the X = H and X = HO cycles come mainly from the attack on water vapour of excited oxygen atoms, $O(^1D)$, formed by the photolysis of ozone at wavelengths below 310 nm. These radicals are removed by mutual combination reactions such as

$$HO + HO_2 = H_2O + O_2 \qquad (7)$$

$$HO_2 + HO_2 = H_2O_2 + O_2 \qquad (8)$$

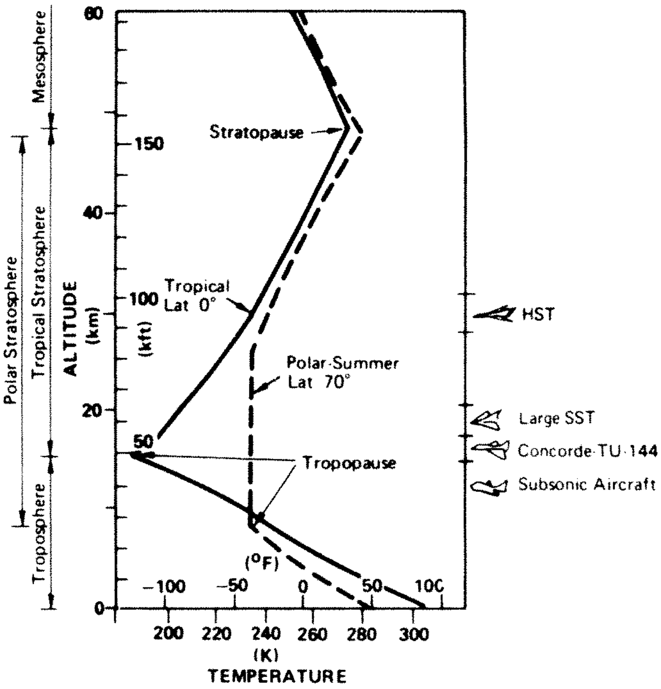

Fig. 1 Temperature of the atmosphere as a function of altitude.

Figures 2 and 3 illustrate the basic corresponding cycles for X = NO and X = Cl (ref. 7). Here man-made compounds may contribute to ozone destruction. Increased use of nitrogenous fertilisers could lead to significantly increased levels of nitrous oxide in the atmosphere, but the natural sources and sinks of nitrous oxide (N_2O) in the troposphere are not well enough known for an assessment of this effect. The amounts of NO and NO_2 in the stratosphere (totalling about 1 part in 10^8) are also enhanced by their presence in the exhausts of high flying aircraft, but 'rain out' in the troposphere prevents the vastly greater quantities of NO and NO_2 released by combustion processes at or near ground level from reaching the stratosphere. Even allowing for the fact that the efficient decomposition of NO_2 by near ultraviolet sunlight and the subsequent reaction (2)

$$NO_2 + h\nu(\lambda < 400\ \text{nm}) = NO + O \qquad (9)$$

$$O + O_2 + M = O_3 + M \qquad (2)$$

$$NO_2 + O_2 + h\nu = NO + O_3 \qquad (9)+(2)$$

effectively reverse the ozone destruction process

$$NO + O_3 = NO_2 + O_2 \qquad (10)$$

the nitrogen oxides provide the strongest removal process for odd oxygen. However, man's efforts in adding to the stratospheric burden of nitrogen oxides or chlorine compounds cannot be assessed directly from this, as recent laboratory studies[8,9] have established the rapidity of the reaction

$$HO_2 + NO = HO + NO_2 \qquad (11)$$

which, like the closely related process

$$ClO + NO = Cl + NO_2 \qquad (12)$$

does not itself remove odd oxygen, but links the odd oxygen destruction cycles so that the effects of nitrogen oxides, halogens, and so on, on ozone are not additive. On this basis it is believed that current and forecast amounts of stratospheric flight (for example, by Concorde and Boeing SP747) will have a negligible effect on stratospheric ozone, but the effects of chlorine compounds are magnified[9–11].

The present levels of chlorine in the stratosphere (1.5–2 parts in 10^9) arise mainly from methyl chloride[12] (from algae and from slash-and-burn agriculture), from salt spray and from volcanic gases. These sources will soon be overtaken by the chlorofluoromethanes $CFCl_3$ and CF_2Cl_2 now present at 1 and 2 parts in 10^{10} respectively in the troposphere[13]. These compounds, which are used as aerosol propellants, refrigerants and foam-blowing agents, have no known natural removal process other than transport into the stratosphere followed by decomposition to yield chlorine atoms, and eventual removal as hydrogen chloride, a process which takes 5–10 years. However, 90% of the halocarbon will remain in the troposphere under uniform mixing conditions because this region contains 90% of the molecules in the atmosphere. The atmospheric lifetimes of $CFCl_3$ and CF_2Cl_2 are therefore believed to be 50–100 years, over which period the depletion of ozone is predicted to increase to near 15% if these substances continue to be released at current rates. However, uncertainties in the rate coefficients of the 50–100 reactions involved and in the transport parameters each contribute a factor of two to the uncertainty of such estimates[7,10]. Another source of uncertainty is the 'unknown chemistry' involving perhaps compounds such as HO_2NO_2, $ClONO_2$ and HOCl which have very limited stability in the laboratory but might be present in the stratosphere in amounts approaching the current detection limits (about 1 part in 10^9).

Verification of the model calculations depends on reliable measurements of trace species in the atmosphere which, with the exception of ozone, are few in number and show significant fluctuations apparently associated with the past history of the air masses sampled. For this reason, simultaneous measurements of a number of trace species are now considered particularly important, as they can provide a better test of the correct identification of the reactions interconverting these species. For instance, the ratio of NO_2 to NO at 20–25 km altitude is predominantly controlled by the rates of reactions (9), (10) and (13)

$$O+NO_2=NO+O_2 \qquad (13)$$

giving

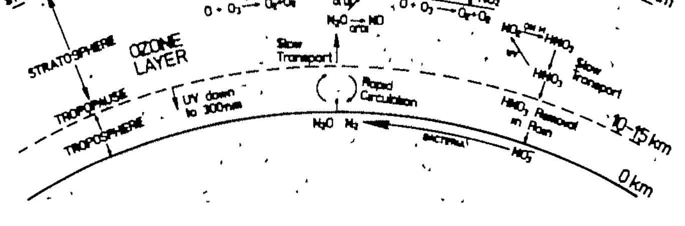
$$\frac{[NO_2]}{[NO]}=\frac{k_{10}[O_3]}{J_9+k_{13}[O]}$$

the ratio of $[O_3]$ to [O] being governed by processes (2) and (3). Thus, the measurement of the ratio $[NO_2]/[NO]$ at these and at higher altitudes where reactions (11) and (12) become significant can verify the accuracy of our understanding of stratospheric chemistry. For these species, the measurements are normally carried out by long path infrared spectroscopy of the setting sun when the ratio of NO_2 to NO is increasing rapidly because the photolysis of O_3 and NO_2 is declining markedly and agreement with the model is not yet perfect[14]. Anderson *et al.*[15] has measured Cl and ClO concentrations at altitudes of 25–40 km by balloon flying and parachuting a flow apparatus in which chlorine atoms are detected in fluorescence either as initially present or produced by reaction (12). The values which he finds are too high to be readily reconciled with measurements of HCl at lower altitudes (with which it should be in steady state, as indicated in Fig. 3) or with known ozone concentrations. This and evidence for a seasonal variation make simultaneous measurements of Cl, ClO, HO and O or O_3 a high priority experiment.

Tropospheric chemistry

Here, as with stratospheric chemistry, much of the recent research has been governed by pollution problems. Historically, sulphur dioxide has been the most important air pollutant in the UK and although its concentration in urban air has been greatly reduced by the use of alternative fuels and by dispersal through high chimneys, the mechanism of its oxidation over a period of weeks before its deposition as sulphuric acid in rain or as sulphate aerosol is far from understood. Homogeneous reactions involving combination reactions with HO in unpolluted and HO_2 in polluted atmospheres are believed to be important and there is evidence for a catalytic process involving transition metals, notably manganese, in polluted atmospheres[16].

Fig. 2 Dominant ozone formation and removal processes in the natural atmosphere.



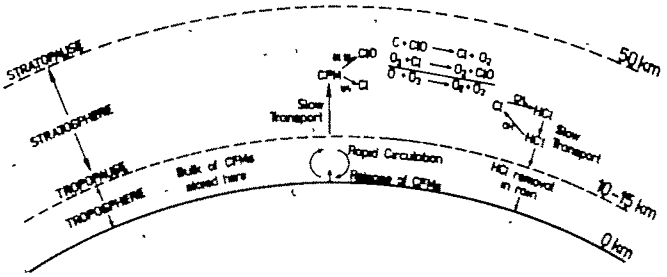


Fig. 3 Simplified diagram of the behaviour of chlorofluoromethanes in the atmosphere.

With an increase in the use of cars, the place of the traditional London fog is beginning to be taken by photochemical smogs which have been a familiar problem in the USA for at least 20 years. These occur when a temperature inversion in sunny weather prevents the dispersal of the exhaust gases of internal combustion engines. The photolysis of NO_2 (reaction (9) above) produces oxygen atoms, these and the ozone which they produce by combination with molecular oxygen (reaction (2)) attack particularly the unsaturated hydrocarbons which are also present in car exhausts. This initiates a highly complex series of oxidation reactions involving particularly the free radicals HO and HO_2 which yield *inter alia* aldehydes and the hitherto unknown peroxy-acyl nitrates ($RCO.OONO_2$), which like the ozone also present are powerful irritants. Carbon monoxide is also oxidised to carbon dioxide. Computer models of the very complicated series of reactions which are believed to occur in smog can now reproduce the smog in laboratory chambers from known materials and also the diurnal variation of the main species involved in the atmosphere, but many individual steps require laboratory measurements[17]. A recent development has been the detection of nitrosamines in Los Angeles smog when sources of aliphatic amines are present[18].

Anthropogenic sources of ozone may well be important even in apparently unpolluted regions of the lower atmosphere. Fishman and Crutzen[19] have recently pointed out that the preponderance of land in the Northern Hemisphere results in three times as much ozone destruction at the surface there compared with the Southern Hemisphere but there is no evidence of a corresponding ratio of ozone fluxes downwards from the stratosphere; this would be required if this were the main ozone source. They conclude that there must be significant tropospheric sources of ozone in the Northern Hemisphere and suggest that these are anthropogenic: the oxidation of hydrocarbons and the oxidation of carbon monoxide

$$CO+HO=CO_2+H \qquad (14)$$

$$H+O_2+M=HO_2+M \qquad (15)$$

$$HO_2+NO=HO+NO_2 \qquad (11)$$

$$NO_2+h\nu=NO+O \qquad (9)$$

$$O+O_2+M=O_3+M \qquad (2)$$

giving

$$CO+2O_2=CO_2+O_3$$

As in the stratosphere, the HO radicals which catalyse these oxidations are produced by the reaction with water vapour of a small portion of the excited oxygen formed in the photolysis of ozone at short wavelengths

$$O_3+h\nu(\lambda<310\ \text{nm})=O_2+O(^1D) \qquad (16)$$

$$O(^1D)+H_2O=HO+HO \qquad (17)$$

Hydroxyl is the most reactive trace species in the troposphere and is therefore the dominant scavenger of many anthropogenic substances such as CO, hydrocarbons and halocarbons containing C—H and C═C linkages. Its concentration in the unpolluted troposphere is so low that it has proved very difficult to measure, but it is currently believed to be about 3 parts in 10^{14} at ground level, which may be compared with a value of 3 in 10^{10} in the stratosphere above 40 km where it contributes significantly to ozone removal.

Reaction with HO gives estimated tropospheric lifetimes of 2 weeks and 10 yr respectively for the important solvent molecules $CHCl{=}CCl_2$ and $CH_3.CCl_3$, which is progressively replacing it. In fact measurement of the atmospheric concentration of a compound such as $CH_3.CCl_3$ with well-known and wholly anthropogenic sources may well provide the best method for determining the average concentration of HO in the troposphere and thus its ability to remove other species from the lower atmosphere. CCl_4 is, like $CFCl_3$ and CF_2Cl_2, present in the troposphere at the 1–2 parts in 10^{10} level[13], being also unreactive towards HO. There is no obvious natural source or tropospheric removal process for CCl_4 and, as this substance is now mainly used as a chemical intermediate, it is plausible that the present quantities in the atmosphere have persisted from the time when it was used extensively as a solvent.

In an article of this length it is only possible to touch on a limited number of the topics of current interest in atmospheric chemistry. Such important but complex problems as the evolution of the Earth's atmosphere and natural cycles of such species as nitrous oxide have been omitted in favour of areas on which there have been particular emphasis in the past few years.

Solar–terrestrial influences on weather and climate

George L. Siscoe

Department of Atmospheric Sciences, University of California, Los Angeles, California 90024

During the past century over 1,000 articles have been published claiming or refuting a correlation between some aspect of solar activity and some feature of terrestrial weather or climate. Nevertheless, the sense of progress that should attend such an outpouring of 'results' has been absent for most of this period. The problem all along has been to separate a suspected Sun–weather signal from the characteristically noisy background of both systems. The present decade may be witnessing the first evidence of progress in this field. Three independent investigations have revealed what seem to be well resolved Sun–weather signals, although it is still too early to have unreserved confidence in all cases. The three correlations are between terrestrial climate and Maunder Minimum-type solar activity variations, a regional drought cycle and the 22-yr solar magnetic cycle, and winter hemisphere atmospheric circulation and passages by the Earth of solar sector boundaries in the solar wind. The apparent emergence of clear Sun–weather signals stimulated numerous searches for underlying physical causal links.

ACTIVE interest in the field of Sun–weather relationships is probably higher at the present time than it has ever been in the past. Since 1972 there have been six major national or international conferences on the subject. The literature is correspondingly very large, and readers interested in going beyond what will be emphasised in this short review should consult the proceedings that have (or will have) emerged from some of these conferences[1–3], and also the extensive references contained in a recent review by Pittock[4].

Solar variability

The subject of Sun–weather relationships is built out of correlations, real or apparent, between changes in solar activity and changes in terrestrial weather and climate. No matter how variable might be the terrestrial atmosphere, if the Sun did not vary, there would be no such subject. It is therefore useful to begin with a brief account of solar variations. These fall naturally into distinct time divisions, the most familiar of which is the 11-yr sunspot cycle. There is also a 22-yr oscillation in the magnetic polarity of the leading member of sunspot pairs, the so-called Hale magnetic cycle. A longer variation of very roughly 80 yr, referred to as the Wolf–Gleissberg cycle, is seen in sunspot cycle amplitudes, as measured for example by the annual mean sunspot number.

On an even longer timescale, there is an important, recently rediscovered kind of solar variation which is typified by the now-famous Maunder Minimum, an interval in the history of solar activity extending approximately from AD 1645 to 1715 (ref. 5) The Maunder Minimum is remarkable for the near-complete absence of spots on the face of the Sun, and a concurrent absence from terrestrial skies of the aurora, a good local indicator of solar activity. It is now generally believed that ^{14}C anomalies detected in tree rings of known, specific ages mark times in the past when other weak solar activity episodes have occurred[6,7]. Episodes of anomalously strong solar activity are indicated as well. The intervals between anomalies vary, but are perhaps characteristically around 400 yr There is also a hint of a slower variation with a period around 2,500 yr associated with clustering of anomalies of the same sign.

On timescales less than the 11-yr period of the sunspot cycle, there are annual and semi-annual variations in geomagnetic and auroral activity resulting from orbital variations in the efficiency with which solar activity energises the Earth's magnetosphere. On still shorter timescales, there is the 27-d period of the solar

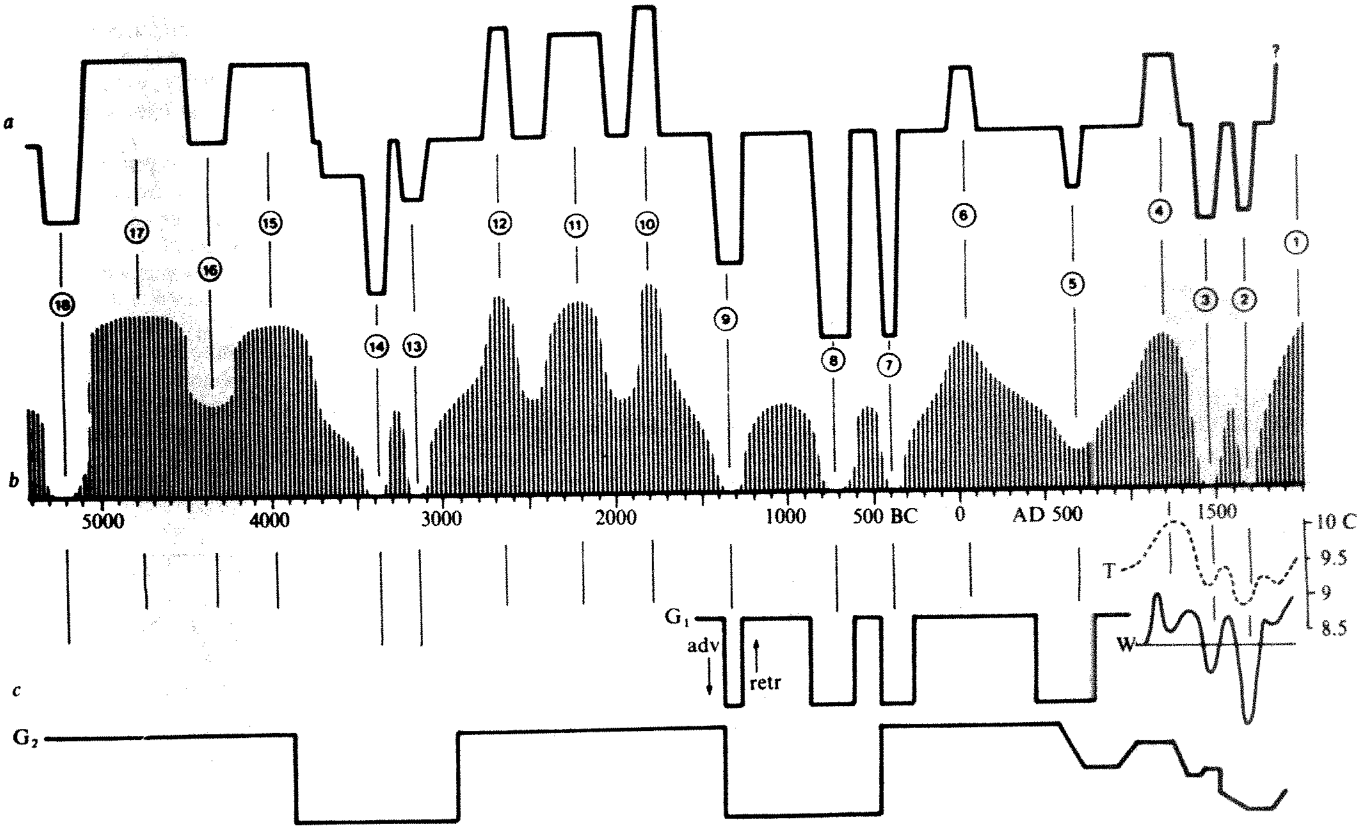

Fig. 1 From Eddy[7]. *a*, Persistent deviations in ^{14}C plotted schematically and normalised to feature 2 (Maunder Minimum); downward excursions refer to increased relative ^{14}C and imply decreased solar activity. *b*, Interpretation of curve *a* as a long-term envelope (of possible sunspot cycle) that minimises in features 2, 3, and so on, and maximises at 4, 6, and so on. *c*, Four estimates of past climate. Step-curve G_1: times of advance and retreat of Alpine glaciers, after Le Roy Ladurie[16]. Curve G_2: same for worldwide glacier fluctuations, from Denton and Karlen[17]. Curve T: estimate of mean annual temperature in England (scale at right), after Lamb[18]. Curve W: winter-severity index for Paris–London area, from Lamb[19], downward is colder.

rotation, and the variable, but approximately 8-d spacings between passages by the Earth of solar sector boundaries. In addition, at irregular intervals, solar flares produce geomagnetic storms which persist typically for 1–2 d.

Terrestrial atmospheric responses to all of the solar activity variation types listed above have been claimed or suggested, with the exception of the annual and semi-annual variations which would be impossible to detect against the background of the yearly succession of the seasons. A panel composed of participants at the symposium held recently at Ohio State University came to the historically unprecedented conclusion that three of the claimed correlations must now be granted the status of reasonable to virtual certainty. These three, correlations with Maunder Minimum-type episodes, the Hale magnetic cycle, and sector boundary passages, will be emphasised in the limited space available here. Other possible correlations, such as with the sunspot cycle and with the solar rotation, however, retain the controversial status that has traditionally characterised claims of Sun–weather correlations.

Maunder Minimum-type episodes

Atmospheric responses to the kind of changes in the Sun for which the Maunder Minimum is archetypal are of the clearest sort, global changes in climate[5–7]. The Maunder Minimum itself together with the preceding Spörer Minimum (AD 1420–1570) coincide with the two coldest excursions within the Little Ice Age, a period encompassing approximately the fifteenth to seventeenth centuries, when the surface temperatures in Europe and America were depressed by 0.5–1°C. In the case of the Maunder Minimum, the climatic event is linked directly to anaomalous solar behaviour through an ample record of telescopic observations of the Sun covering the period in question. Earlier climatic excursions, such as the Spörer Minimum and the Mediaeval Climatic Optimum, a globally warm period during the twelfth century, are linked to solar changes through proxy data. Foremost among these in importance is the tree-ring record of ^{14}C anomalies, which are believed to result when a change in the level of solar activity varies the flux of ^{14}C-producing galactic cosmic rays that can penetrate the Solar System to Earth's orbit. High solar activity reduces the galactic cosmic ray flux at Earth, which depresses the rate of ^{14}C production. The opposite condition characterises periods of attenuated solar activity. When the curve of tree ring ^{14}C anomalies is compared with the curve of climatic variations, in the words of J. A. Eddy, who has convincingly promoted and applied the field of long-term solar changes, "the correspondence, feature for feature, is almost the fit of a key in a lock" (see Fig. 1)[7].

Before the ^{14}C studies, the same long-term Sun–climate correlation had been recognised by J. R. Bray[8,9], using the solar activity index constructed by J. D Schove[10] from historical observations of aurorae and naked-eye sunspots. A more recent and more extensive compilation of historical aurorae which combines occidental and oriental observations also shows the existence of major solar activity features corresponding to the major climatic excursions[11]. Although the presently known auroral record becomes too fragmentary before the first few centuries of the Christian Era to identify solar activity episodes of the Maunder type, it may serve to validate for that purpose the use of the much longer record of tree-ring ^{14}C anomalies.

Hale magnetic cycle

The correlation that has been found linking atmospheric behaviour and the (approximately) 22-yr solar magnetic cycle involves a modulation of regional climate. The Great American Desert, which is centred roughly in the southwestern US and northern Mexico, has long been known to expand and contract its area of influence with a timescale of about 20 yr producing cycles of drought in the region west of the Mississippi River. The 'dust bowl' of the 1930s and the droughts of the 1950s and 1970s are the most recent of its intensifications and expansions. Many people have suspected and presented evidence to show that the drought cycle is related to the Hale double sunspot cycle[12–14]. Until recently the record length was too short and the drought cycle was not quantified, so that statistical tests of the proposed correlations were difficult to perform.

Mitchell and Stockton have now succeeded in quantifying the temporal climatic behaviour of the desert with a single parameter, yearly index extending back to at least AD 1700 constructed out of tree-ring indices from 40 regionally distributed, climatically sensitive sites[15]. (Actually three families with four sets of such indices were generated to establish internal consistency of the procedure.)

Power spectral analyses of the obtained data sets, so-called drought area indices (DAI), revealed well defined concentrations of power at periods near 22 yr, at formal significance levels ranging from 95% to more than 99%. The analyses were based on sets of 262 data points from the time interval 1700–1962, which included approximately 12 complete Hale cycles. Phase locking between the succession of Hale magnetic cycles and the cycles of drought area was demonstrated to exist at formal significance levels exceeding 99%. Thirdly, the amplitudes of the drought cycles vary from one to the next in a way that bears a strong resemblance to the envelope of the amplitudes of the Hale sunspot cycle. The linear correlation between the two data sets is statistically significant at between the 95 and 99% levels. Weak sunspot cycle amplitudes tend to correspond to minimum drought conditions, but the authors are quick to point out that the apparent correlation is not a reliable basis for operational climate prediction.

Although Pittock[4] has urged caution in accepting at face value the inferred Sun–weather correlation because "complex questions are involved in assessing the true statistical significance of the result", the Hale solar cycle–regional climate connection must be considered at least a serious possibility in view of its having survived the three levels of statistical tests. Full confidence in the result will most likely be achieved only if it is independently confirmed by other researchers who, like Mitchell and Stockton, have a critical attitude toward testing its reality. Such confirmation has been secured by the third of the cited correlations, which is described next.

Solar sector boundary passages

A line of investigation focused on the possibility that geomagnetic activity (a solar effect) may influence atmospheric circulation emerged in the 1950s (refs 20–23). It evolved in cast and sophistication under the stimulus of consistently positive findings until a rigorous statistical test of a specific form of the hypothesis recently could be made[24,25]. The crucial point was reached when two operationally specified, objective data sets were identified, one representing atmospheric circulation, and the other containing a statistically significant number of 'solar' events that could be used for the purposes of a correlation analysis.

The solar input to the correlation is a list of the times of passages by the Earth of solar wind sector boundaries. Sectors are regions in the solar wind, first recognised by Wilcox and Ness[26], that have predominantly one magnetic polarity, either toward or away from the Sun, and they are separated from adjacent sectors of opposite polarity by thin, usually well defined boundaries. Magnetic sectors and their boundaries tend to co-rotate with the Sun. Normally there are either two or four sectors at any given time. Magnetic sector boundaries have been shown to be natural time markers, that bear a temporally fixed relationship to the progression of a variety of solar wind phenomena. By mapping them back to their origins on the Sun, they become also natural space markers for solar features.

The atmospheric input to the correlation is a derived quantity called the vorticity area index (VAI) first defined by Roberts and Olson[24]. On a map of a constant pressure surface in the atmosphere (usually the 300 mbar level, but the correlation is also evident at 500 mbar), absolute vorticity contours are drawn at selected vorticity levels. The VAI is based on the portion of the map for the Northern Hemisphere north of 20° N, and is defined as the sum of the area (in square kilometres) over which the absolute vorticity exceeds $20\times10^{-5}\,s^{-1}$ plus the area over which it exceeds $24\times10^{-5}\,s^{-1}$. The index is specifically designed to measure the intensity and extent of low pressure troughs, which may roughly be thought of as large 'bad weather' systems.

Wilcox *et al.* have carried out a superposed epoch analysis on the VAI, using as zero days the times in a previously published list of solar sector boundary passages[27–32]. The results of their analysis based on 54 boundaries, reproduced in Fig. 2, shows an evidently statistically significant feature, of about a 6-d temporal width, centred approximately 1 d after the boundary passage, at which time the vorticity area index is depressed about 10% relative to adjacent values. The apparent signal was clearly evident only for the winter months and was entirely absent for the summer months.

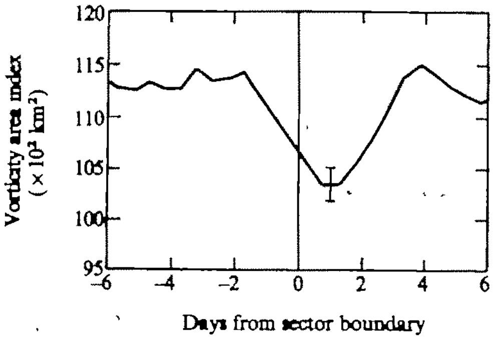

Fig. 2 From Wilcox *et al*[27]. Average response of the vorticity area index (the area of all the low pressure troughs in the Northern Hemisphere) based on the times of 54 solar magnetic sector boundary passages by Earth

The relatively short timescale of this particular claimed Sun–weather effect, less than 2 weeks, and the comparatively long interval over which VAI data were available, many years, permitted extensive testing of the statistical properties of the index over the appropriate timescale. Hines and Halevy[33,34] have undertaken the task of searching for an explanation of the alleged correlation in terms of accidental properties of the two data sets (such as having a common period of variation but derived from known, independent causes) but none was found. They ultimately concluded that either the correlation was real or it was a random fluctuation for which their analysis of the data provided a formal *a priori* probability of one chance in 20. Shapiro has carried out a similar analysis and reached the same conclusion[35]. Both critics of the claimed correlation pointed out, however, that the *a priori* probability is really not applicable because the data were in some respects selected *a posteriori*, only winter months, only a certain height interval in the atmosphere, and so on.

The issue was decided in favour of the reality of the correlation when a list of times of additional boundary passages was compiled, containing more than the original number of entries. Only if the correlation were real would one expect the signal seen in Fig. 2 to reappear in essentially identical form from a superposed epoch analysis based on the new list of times. After performing the critical test and discovering the same signal, Hines and Halevy were forced to conclude that "the alleged solar signal should be accepted as a physically meaningful signal whose origins should now be sought"[34,36].

Other correlations

Within the past century over 1,000 articles have been published asserting or refuting a claim of some form of Sun–weather influence. Most of these are concerned with correlations with the 11-yr sunspot cycle. King has published a veritable catalogue of such claimed correlations[37]. The whole field of 11- and 22-yr correlations has been critically discussed in a recent, thorough review by Pittock[4]. Multiple claims of sunspot correlations have been made for atmospheric pressure, temperature, precipitation, thunderstorms, tropopause height, and ozone, and isolated claims for an assortment of other weather–climate variations. Pittock, while reserving judgment on the new results on the drought cycle in the Western United States, concludes for the rest that "despite a massive literature on the subject, there is at present little or no convincing evidence of statistical significant or practically useful correlations between sunspot cycles and the weather or climate". Some advocates in the Sun–weather community are likely to disagree.

When statistical tools are needed to determine the reality of a correlation, especially a non-predictable one, absolute certainty will never be achieved. Instead, levels of conviction are achieved, and for the same statistical data, these vary between individuals according to whether they are advocates, agnostics or critics. Pittock's conclusion tells us that there is not yet in the field of sunspot–weather relations a single correlation with enough statistical punch to convince a critic of its reality.

It might turn out that some of the correlations are real, but a common problem that weakens the statistical approach is the shortness of the atmospheric data record compared to a signal period of 11 or 22 yr. In some cases it may be possible to extend the data record, for example through the use of proxy data, as was done for the drought cycle, with a resultant considerable increase in the strength of the statistical evidence.

As an alternative solution to the short data record problem, correlation seekers have been advised by Roberts[38] to concentrate more on short-term responses of the atmosphere to solar activity variations. The sector boundary correlation with the vorticity area index stands as a model of what can be achieved in this way. Geomagnetic and solar surface variables have been found to correlate with the VAI as well[39]. Other short-term correlations have already been suggested or claimed, such as between sunspots and quasi-biennial variations in the stratosphere[40], between the solar rotation and large amplitude standing planetary waves in the atmosphere[41], and between geomagnetic activity and a behaviour characteristic of persistence in the sea-level pressure distribution[42]. These have yet to be subjected to critical independent review.

One recently claimed short-term correlation needs to be mentioned. Attempts based on correlations with the 11-yr sunspot cycle to determine if there is a variation of global ozone with solar activity have been inconclusive. Keating[43], following a suggestion of London and Oltmans[44], has correlated monthly averaged variations of global ozone, determined from a remote sensing detector aboard the Nimbus 4 satellite, with solar activity as measured by the monthly mean 10.7 cm solar electromagnetic flux. A correlation exceeding the 95% level of confidence was found, although only 10 months of data were available for the study. The relative amplitude of the ozone variation over the study period was slightly greater than 0.1% compared with the average.

The possibility that some property of atmospheric ozone may be influenced by solar activity, which now needs to be independently confirmed or refuted with different data sets, is especially important because of the central role that ozone modulations play in current thinking about mechanisms for Sun–weather connections. It seems clear that the subject of Sun–weather connections will have the appearance of an underdeveloped science until at least one physical causal link (or one complete chain of causal links) has been verified. The determination of operating physical mechanisms would then provide a powerful means, for example, through inclusion in numerical climate models, to answer questions about the solar activity influences on specific weather–climate behaviour.

Mechanisms

It is generally recognised that there may be more than one cause and more than one effect involved in the total atmospheric response to the complex of variations that make up solar activity. The most obvious possibility, solar activity-related variation in the solar constant which powers the weather machine, remains an attractive possibility. This is true especially for the longer-term correlations, even though a recent assessment concludes that the solar constant has remained unchanged to within 0.75% over the last half of the previous solar cycle[45]. An analysis by Volland finds that planetary-scale pressure waves driven by a 0.1% 27-d oscillation of the solar constant would have detectable amplitudes[46,47]. In view of the simple direct consequences of small variations in the solar constant, there is a consensus that long-term, high-precision measurements of it would be very desirable.

Regarding Maunder Minimum-type variations, Eddy points out again that the simplest and most straightforward explanation is that solar behaviour includes a series of long-term changes in the solar constant, in this case with an amplitude of the order of perhaps 1% (refs 6 and 7). In his view, solar constant variations modulate the envelope of sunspot cycle amplitudes, accounting for the observed correlations with solar activity.

Other possibilities for explaining long-term correlations nevertheless exist. Changes in the thermal structure of the stratosphere are shown by Bates to be capable of significantly affecting the ability of the lower atmosphere to transport heat from the Equator to the Pole[48]. The thermal structure of the stratosphere can be influenced by solar activity through its modulation of solar ultraviolet radiation, which is stopped in the stratosphere[49,50], and through its supposed modulation of stratospheric ozone, which absorbs part of the solar ultraviolet. Another avenue of influence connects the same solar activity modulation of galactic cosmic rays that produces the ^{14}C anomalies in tree rings with the tendency of such cosmic rays to deplete ozone in the stratosphere, indirectly through a chain of stratospheric chemistry[51,52].

In spite of these promising leads concerning long-term correlations, it seems fairly obvious that explanations in terms of variations of one or another solar electromagnetic flux will not account for the VAI correlation with sector boundary passages. If we adopt the position expressed by Hines and Halevy, that it is time to search for the mechanisms behind this correlation, we are faced with the prospect that the responsible agents are probably part of the complex of solar particle fluxes, including the solar wind and solar cosmic rays; in which case the complete story of causal linkages will have to include the interaction of these particles with Earth's magnetosphere, and the subsequent interaction of the magnetosphere with the atmosphere.

Investigators attempting to discover such linkages have been adequately warned that the solar particle fluxes contain negligible energy compared to weather systems with which they are supposedly correlated[53,54]. On the other hand two studies show that the sector boundary–VAI correlation does not involve a detectable change in atmospheric energetics[55,56]. The situation thus favours the kinematical explanation offered by Hines and Halevy, in which phase shifting of pre-existing meteorological noise is invoked to produce the observed coherence[33,34]. The required phase-shift mechanism, however, has not yet been identified.

Present exploration aimed at locating a coupling mechanism that can convert a solar wind stimulus into an atmospheric response on a short timescale is focusing on the magnetospheric particles that precipitate into the upper atmosphere, and which are known to be modulated by the solar wind. Examples are the precipitations that produce the polar aurorae[57], and the rarer but more penetrating "relativistic electron precipitation" (REP) events[58]. Some argue that these may act, for example, through promoting the development of cirrus clouds high in the troposphere[24] or by modifying the elements in the global atmospheric electrical circuit, thereby possibly affecting thunderstorm activity[59].

This short list of ideas is not intended to show that the problem of identifying the causal links connecting solar activity and weather or climate is close to being solved. On the other hand, now that some of the claimed correlations have risen respectably high out of the noise, the problem is receiving increasingly more attention. There is reason for optimism that the next landmark in the field of Sun–weather relationships, the verification of a causal link, may not be far off.

Predictability of climate

C. E. Leith

National Center for Atmospheric Research, P.O. Box 3000, Boulder, Colorado 80307

A mathematical framework is presented for the study of the predictability of small changes in the climatic system. From a statistical definition of climate in terms of ensemble averages, a limit to predictability is found arising from random weather fluctuations. This limit, typically referred to as climate noise, is often able to obscure a possible climate signal produced by external forcing. A separation of timescales of climatic response is also presented as a convenient means to distinguish between the fast internal (for example, the atmosphere) and the slow external (for example, the oceans) systems. In this way, it is possible to estimate the climate signal in the internal system that arises from small changes in the slow external system. Finally, a theoretical approach is presented for the inclusion of possible feedback effects in the estimation of a climate signal. Such feedback effects could result from the external climatic system being influenced by a change in the mean properties of the fast internal climatic system.

In recent years a number of widely publicised anomalies in various parts of the world have greatly increased interest in the predictability of climate for periods of months to decades. In this review I shall define climate, as distinguished from weather, in terms precise enough to serve as a basis for a statistical dynamical theory of small fluctuations. The problem is to separate potentially predictable fluctuations called signals from unpredictable fluctuations called noise. The ratio of signal to noise provides a measure of the predictability of the climate system.

Definition of climate

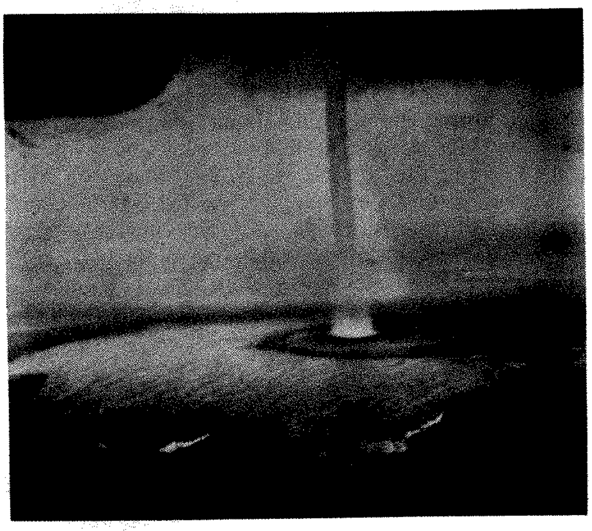
The climate at any place is commonly defined as being the average weather there. A broader definition of the global climatic system includes all the statistical properties of the global atmosphere and the underlying land, sea and ice surfaces. The climate system is thus described in terms not only of mean values but also of variances about the mean, co-variances between variables possibly separated in space and time, probabilities of extreme events, and so on. Specification of the statistical properties of the climatic system involves far more information than does specification of the state of the atmosphere at a given time, but little is known about the statistical moments of the system higher than the second.

The statistical properties of the climate system must be defined in terms of some sort of averaging process and here fundamental difficulties arise. The common, operationally feasible, and natural choice is to compute an average over some time interval T. This permits a continuum of choices depending on T. For small enough values of T the corresponding time-averaged climate would become indistinguishable in its fluctuations from the weather. For greater and greater values of T the corresponding time-averaged climate becomes increasingly

0028-0836/78/0276—0352$01 00

independent of the averaging interval, and we might define a true climate in terms of a limit as T approaches infinity. In addition to the practical difficulty that computing an infinite time average is no longer operationally feasible, there is the major theoretical difficulty that we would now no longer be able to consider climate as changing with time. A conventional compromise is to take T as 30 yr.

Such a compromise definition of climate is awkward for setting up a precise mathematical framework for a theory of climate. This same general difficulty was encountered over a century ago in considering the formulation of a statistical mechanical basis for thermodynamics. In this analogy the detailed motions of gas molecules correspond to the weather and the statistical properties of a gas such as temperature and pressure correspond to the climate. Here too, if one wishes to discuss a situation in which temperature and pressure are changing, one must not define them in terms of infinite time averages.



Waterspout photographed near Florida Keys, 10 September 1969, by J. H. Golden of ERL-NOAA, Boulder, Colorado (note the spiral forming on the surface of the water)

In statistical mechanics this difficulty has been circumvented by introducing the theoretical concept of an ensemble. An ensemble is an essentially infinite collection of copies of the original dynamical system with each evolving in its own natural way. The dynamical state for each copy is specified by giving the values of a large number of dynamical variables, and it can therefore be represented by a point in a multi-dimensional dynamical phase space. At any given time the members of the ensemble will be found at phase points throughout the whole phase space in accordance with some probability distribution. In time the phase points move and thus in general the probability distribution changes. The problem in statistical mechanics is to find an equilibrium probability distribution that does not change with the natural motion of the phase points in order to define statistical properties in terms of the corresponding ensemble average. One may then ask sensible questions about how external influences can modify statistical properties by changing the equilibrium ensemble probability distribution.

The application of this general concept to the climate system is straightforward. One imagines an ensemble of Earths, each subjected to the same external influences, each with the same distribution of continents and oceans, and the weather on each going through normal fluctuations independently of all others. One next imagines that the distribution of states of the weather in the ensemble is chosen in such a way that the probability distribution is unaffected by the rapid weather fluctuations of individual members but can change relatively slowly owing to changing external influences. The climate is then defined in terms of averages over this ensemble. It is immediately evident that this ensemble-averaged climate is an ideal theoretical concept inaccessible by direct observation just as was the infinite time-averaged climate discussed previously. For a system with unchanging external influences, it is desirable for the two definitions to be equivalent. A dynamical system is said to be ergodic or transitive if this is the case.

At this point the objection might be raised that the ensemble-averaged climate is not really what anyone is interested in. We live on only one Earth with a single sequence of weather events and are naturally more concerned about the future behaviour of that single system than in some average behaviour of an imagined ensemble. Accordingly, the most direct way to predict the climate would seem to be to predict the weather and then to average it in time. Unfortunately, we are currently unable to predict most of the variability of the weather beyond a few days. Furthermore, theoretical studies indicate that there exists a limit of a week or so in the range of useful prediction even for a perfect prediction model because of the unstable nature of the atmosphere and the inevitable inadequacies in observations of its detailed initial state.

We adopt then the point of view that the climate is determined by an ideal ensemble and that finite time averages will fluctuate about ensemble values producing what is called climate noise. This climate noise, to be discussed in the next section, arises from the statistical fluctuations of the unpredictable weather and not only obscures the properties of the true climate but also diminishes the value of knowledge of these properties for prediction of the short-term behaviour of the most interesting member of the ensemble, the one which actually exists.

A further question arises in seeking a definition of climate precise enough for research purposes. How does one bound the statistical climate system to distinguish its internal behaviour from external forcing influences? Ideally, this should be done in such a way that the external forcing influences are independent of the state of the internal system. They may be taken, for example, to be the positions of the continents and the incoming solar radiation at the top of the atmosphere. For many model studies of the climate, however, it is useful to specify as external a much larger number of influences such as carbon dioxide content, sea surface temperature, ice sheet thickness and surface albedo. Although the separation between the internal and external systems may be made in many ways, it is important to remember that any feedback influences of the internal system on the external system must either be ignored or treated in an ensemble-average sense. Otherwise, the external system acquires some of the unpredictable random behaviour of the internal system and can no longer be sharply specified.

By judicious location of the boundary between the internal and external systems, we can also implicitly separate time scales of change. The advantages sought in an explicit choice of averaging time scale can instead be obtained by choosing the internal system to include all relatively fast processes. To achieve a time scale separation at a few weeks, for example, the internal system would contain the atmospheric motions and changing land surface temperature, whereas the sea surface temperature would be treated as an external forcing influence.

Climate noise

Perhaps the most familiar example of a sampling fluctuation occurs with the tossing of a coin. Although for a large number of tosses the ratio of heads to tosses is expected to approach one-half, no-one is greatly surprised if 20 tosses result in 7 heads and 13 tails. If 200 tosses, however, were to result in 70 heads and 130 tails, some doubt might be raised as to the fairness of the coin. The theory of such fluctuations is completely understood and can be found in any elementary textbook on probability theory.

A similar example more relevant to the continuous variables of the climate system is the drawing of a sample of n independent values x from an infinite population with mean μ and standard deviation σ. The average $\bar{x}$ of the sample generally will differ from μ, and it is easy to show that many repetitions of the sampling procedure will lead to a distribution of $\bar{x}$ with mean μ and standard deviation $\sigma_n = \sigma / n^{1/2}$.

Averages of a meteorological time series over an interval T have similar fluctuations about the infinite population mean, but in this case sequential observations, if frequent enough, are not mutually independent. This may easily be accounted for[1,2] in terms of an effective time between independent samples

$$T_o = \int_{-\infty}^{\infty} R(\tau)\,d\tau$$

where $R(\tau)$ is the correlation of two values in the time series separated by a time interval τ. For $T/T_0 = n$ sufficiently large, n plays the role of the independent sample size. The standard deviation σ_T of time averages is then related to the standard deviation σ of the time series by

$$\sigma_T = \sigma / n^{1/2} = \sigma (T_0/T)^{1/2}$$

The time T_0, which is an integral time scale for fluctuations of meteorological variables, plays an important part in the determination of climate noise levels. Madden[3] has determined T_0 for sealevel pressure over much of the Northern Hemisphere and finds values with a range 2–8 d.

Tornadoes over Vietnam photographed from a helicopter. Taken from *The Elements Rage* by F. W. Lane (David and Charles, Newton Abbot, UK)

Some part of the fluctuations from year to year in monthly averages of meteorological variables must be attributed to the climate noise arising from sampling fluctuations. As such it represents an unpredictable component, and a key question for climate predictability is how much greater is the variability observed to be than the amount expected from noise. Madden[3] has attempted to answer this question for monthly average sea surface pressures for January and July. He has found that most of the observed interannual variability in midlatitudes seems to be climate noise, whereas in the tropics there is evidence of an additional potentially predictable component.

The existence of an unpredictable noise component in finite time averages limits the practical utility of any predicted shift $\Delta\mu$ in the climate mean μ which we may appropriately call a climate signal. Unless the signal-to-noise ratio $\Delta\mu/\sigma_T$ is greater than about 0.5, the prediction of $\Delta\mu$ may have little utility for prediction of time averages of duration T (ref. 1). Of course, as σ_T decreases at $T^{-1/2}$, for long enough intervals, T, the prediction of $\Delta\mu$ acquires value.

Climate signal

In the previous section I described the climate noise that arises from unpredictable weather fluctuations in the fast internal climatic system. In this section I shall discuss procedures for estimating the climate signal that arises from the influence of the slow external system on the internal system. To the extent that the slow system may be predictable, the coupling of the two systems provides an element of predictability for the fast system.

The usual procedure for determining the response of the internal system is to construct a numerical model of it in which the external influences are treated as specified forcing terms. Symbolically, we may write the model dynamical equations for the unperturbed system as

$$\dot{x}_\alpha = Q_\alpha(x_1, x_2, \ldots, x_N) + f_\alpha$$

Here $x_1, x_2, \ldots, x_N$ are amplitudes of a large but finite number N of modes in terms of which the state of the internal system is defined, $Q_\alpha(x_1, x_2, \ldots, x_N)$ are complicated functions determining the internal dynamics of the system and f_α are forcing terms describing the external influences. For the statistically stationary unperturbed system, we have unchanging ensemble means, that is, $\langle \dot{x}_\alpha \rangle = 0$. If now a step change in forcing δf_α is introduced at time $t = 0$ for all members of the ensemble, then the ensemble means will start to change at a rate $\langle \dot{x}_\alpha \rangle = \langle \delta f_\alpha \rangle$. Because of the stable nature of the climatic system, a new stationary level will be approached with a final change in means given by $\delta \langle x_\alpha \rangle$.

The general procedure in using a numerical model to estimate $\delta\langle x_\alpha \rangle$ is to make long computations with and without the perturbed forcing δf_α, to estimate $\langle x_\alpha \rangle$ in either case by time averages over intervals excluding any initial transient, and to subtract one estimate from the other. The climate noise associated with the time averages tends to obscure small values of $\delta\langle x_\alpha \rangle$. It is usually assumed that small responses are linear and that δf_α may be amplified by a scale factor by which the computed response is later divided.

The first-order linear response of the system can be written as

$$\delta\langle x_\alpha \rangle = \sum_\beta A_{\alpha\beta}\, \delta f_\beta$$

where the matrix elements $A_{\alpha\beta}$, having the dimensions of time, determine the response of the mean of any mode $\langle x_\alpha \rangle$ to a change in forcing of any mode δf_β.

Another procedure provides more detailed information about the time history of the response. Consider an impulsive forcing which is turned off immediately after being imposed at time $t = 0$ on each member of the ensemble. This produces an immediate change $\delta\langle x_\alpha(0^+) \rangle$ which will then tend to zero as the system returns to its original statistical state. For small perturbations the relaxation is described by

$$\delta\langle x_\alpha(\tau) \rangle = \sum_\beta g_{\alpha\beta}(\tau)\, \delta\langle x_\beta(0^+) \rangle$$

where $g_{\alpha\beta}(\tau)$ is a mean linear response matrix function of time τ with $g_{\alpha\beta}(0^+) = \delta_{\alpha\beta}$ the identity matrix. The response to any history of forcing perturbation $\delta f_\alpha(t)$ may be written in terms of $g_{\alpha\beta}(\tau)$ as

$$\delta\langle x_\alpha(t) \rangle = \sum_\beta \int_{-\infty}^{t} g_{\alpha\beta}\,(t-s)\, \delta f_\beta(s)\, ds$$

In particular, for step forcing the infinite time response matrix is given by

$$A_{\alpha\beta} = \int_0^\infty g_{\alpha\beta}(t)\, dt$$

A determination of $g_{\alpha\beta}(\tau)$ from model calculations is probably not feasible, but it can be estimated by statistical analysis of the unperturbed climate system itself. In the course of their natural evolution, the members of the ensemble generate anomalies δx_α from the mean. For a sub-ensemble all of whose members have a given anomaly $\delta x_\alpha(0)$ at time $t = 0$, the sub-ensemble mean perturbation will be $\delta\langle x_\alpha(0) \rangle = \delta x_\alpha(0)$. But it, too, will tend to return to zero in a way that can be estimated by linear regression prediction methods.

The timelagged co-variance matrix for the unperturbed system is

$$X_{\alpha\beta}(\tau)=\langle\delta x_\alpha(t+\tau)\,\delta x_\beta(t)\rangle$$

the regression matrix is

$$R_{\alpha\beta}(\tau)=\sum_\gamma X_{\alpha\gamma}(\tau)\,[X^{-1}(0)]_{\gamma\beta}$$

where $R_{\alpha\beta}(0)=\delta_{\alpha\beta}$, the identity matrix, and the least square estimate of the future mean anomaly of the sub-ensemble is given by

$$\delta\langle x_\alpha(\tau)\rangle=\sum_\beta R_{\alpha\beta}(\tau)\langle\delta x_\beta(0)\rangle$$

The reasonable assumption that the system recovers from a small natural anomaly in the same way that it does from one induced by external forcing leads to the fluctuation dissipation relationship that for $\tau\geqslant 0$

$$g_{\alpha\beta}(\tau)=R_{\alpha\beta}(\tau)$$

According to the fluctuation dissipation theorem$^{4-7}$, this relationship holds exactly for dynamical systems with a gaussian Maxwell–Boltzmann equilibrium probability distribution. Such is not the case for a dissipative turbulent system such as the atmosphere, but experience with turbulence models has indicated that the approximation may nonetheless be fairly good.

One is faced with the choice of estimating $g_{\alpha\beta}(\tau)$ for the internal climatic system either as given by $R_{\alpha\beta}(\tau)$ for the system itself or as given by $g_{\alpha\beta}(\tau)$ for a numerical model of it. Confidence in the results would be greatly enhanced if the two quite different approaches gave similar answers, and this confidence would extend to model results for perturbations beyond the linear domain of the fluctuation dissipation relationship.

Qualitative properties of climate signals may be deduced from known qualitative properties of correlations using the fluctuation dissipation relationship, as regression functions are qualitatively like correlation functions. These have a spatial extent in midlatitudes of a few thousand kilometres, and the climate response to a local forcing perturbation should be similarly limited in spatial extent. This suggests that the climatic system may be considered as a collection of more or less independent regional climatic systems.

As the diagonal regression coefficients $R_{\alpha\alpha}(\tau)$ are qualitatively like the single variable lagged correlation function $R(\tau)$ discussed in the previous section, a qualitative estimate of the step response coefficients for the fast internal system is given by

$$A_{\alpha\alpha}=\int_0^\infty R_{\alpha\alpha}(\tau)\,d\tau\approx T_0/2\approx 3\text{ days}$$

The internal climatic system adjusts therefore within a week or so to a new level with a change in mean values $\delta\langle x_\alpha\rangle$ given by the initial rate of change δf_α multiplied by a characteristic response time of a few days.

Feedback effects

It has been assumed that the external climatic system is not influenced by the mean or fluctuating properties of the fast internal climatic system. The feedback influence of mean effects, however, may be included rather easily to first order by linear analysis. It is convenient here to replace matrix elements by matrix notation so that the step forcing response equation becomes

$$\delta\langle\mathbf{x}\rangle=\mathbf{A}\,\delta\mathbf{f}$$

Suppose now that a change in mean properties $\delta\langle\mathbf{x}\rangle$ in the internal system forces a change in the external system leading eventually to an additional change in forcing $\delta_1\mathbf{f}$ which to first order is given by

$$\delta_1\mathbf{f}=\mathbf{B}\,\delta\langle\mathbf{x}\rangle$$

The combined effects are then given by

$$\delta\langle\mathbf{x}\rangle=\mathbf{A}(\delta\mathbf{f}+\mathbf{B}\delta\langle\mathbf{x}\rangle)$$

so that we have

$$\delta\langle\mathbf{x}\rangle=(\mathbf{I}-\mathbf{B})^{-1}\,\mathbf{A}\,\delta\mathbf{f}$$

The feedback effect matrix $(\mathbf{I}-\mathbf{B})^{-1}$ can either increase or decrease the response $\delta\langle\mathbf{x}\rangle$ from that with $\mathbf{B}=0$.

The response of the external system is assumed to be slow and, for this present analysis, non-random. The response properties leading to the matrix $\mathbf{B}$ may therefore be determined relatively easily using a numerical model of the external system that includes the appropriate slow physical processes.

As with the internal system, it is possible to determine the more detailed time history of the feedback response of the external system. Qualitatively, a step change $\delta\mathbf{f}$ induces a rapid change $\delta_0\langle\mathbf{x}\rangle$ which induces a slow change $\delta_1\mathbf{f}$ which induces a further slow change $\delta_1\langle\mathbf{x}\rangle$ to the final value $\delta\langle\mathbf{x}\rangle=\delta_0\langle\mathbf{x}\rangle+\delta_1\langle\mathbf{x}\rangle$ given above.

The additional feedback influence of the random fluctuations in the internal system has been discussed by Hasselmann^8 and others^{9,10}. Now the external system becomes random and Hasselmann considers one that can be modelled by a Langevin equation of the general form

$$\dot{\mathbf{y}}=-\mathbf{D}\mathbf{y}+\mathbf{g}$$

Here $\mathbf{y}$ represents anomalies in the external climatic system, $\mathbf{D}$ is a matrix which is positive definite to provide stability and $\mathbf{g}$ is a random white forcing term that models the effects of the rapid fluctuations of the internal system. The resulting behaviour is analogous to damped brownian motion with the external system playing the part of the particle and the internal system that of the molecular motions. By suitable choice of $\mathbf{D}$ and the strength of $\mathbf{g}$, it has been possible to model the frequency spectrum of sea surface temperature fluctuations considered as part of the external system^{9,10}. Some predictability of the external system is provided for the Langevin models by the mean regression equation

$$\langle\dot{\mathbf{y}}\rangle=-\mathbf{D}\langle\mathbf{y}\rangle$$

Discussion

In this review I have described the mathematical framework for the study of the predictability of those small changes in the climate for which a linear analysis is appropriate. For larger changes a non-linear numerical climate model must be used.

Much work has yet to be done to fill in this framework. There is already fair evidence for useful climate predictability in equatorial and tropical regions where the noise level is small, but there is only fragmentary evidence for it in midlatitudes.

Finally, the possibility of extending the range of deterministic prediction of relatively stable internal configurations of the sort that arise in atmospheric blocking events is of great practical importance. But this would be a prediction of weather rather than of climate as strictly defined in this review.

Predicting temperature trend in the Northern Hemisphere to the year 2000

M. K. Miles*

The cooling of the Northern Hemisphere since 1940 has been variously interpreted as the overture to the next Ice Age, the effect of industrial pollution in the atmosphere or of a decline in the solar output. Are we in a position to judge between these various interpretations and to make a prediction for the next few decades? The link with the next Ice Age may be dismissed as a confusion of timescales; the explanation in terms of atmospheric pollution merits careful examination but seems unlikely to be adequate on its own. Natural fluctuations must also be considered.

THE annual surface temperatures of the Northern Hemisphere from 1951 to 1975 given by Kukla *et al.*[1] show that year to year differences equalled or exceeded 0.3 °C eight times in this period. These changes do not constitute climate as generally understood, although they may be very important for world agriculture or transportation. There are various views on how long a period we should average this temperature over to arrive at the value which is to be the subject of climatic predictions.

How 'noisy' is the temperature record?

The data themselves do not give us much guidance: variations seem to occur on all time scales from a year to millennia. Claims have been made at various times that at some particular frequency (2.2 yr, 11 yr, 88 yr, 200 yr, and so on) there is a marked periodicity, but the variability associated with any of these is usually a small part of the total: no period stands out so clearly from the rest that we can on this basis select an appropriate averaging period.

The spectrum is not, however, simply a 'white noise' one with all frequencies equally represented: there is a notable tendency for there to be more variation at periods above about 10 or 20 years than a white noise spectrum would contain. This I interpret as meaning that it may not be a fruitless task to try and say something about the future trend of means taken over 5 or, perhaps better, 10 yr.

Figure 1 shows the course of decadal means of Northern Hemisphere surface temperatures for the past 100 yr. These have a standard deviation of 0.17 °C but the deviations are not randomly distributed. A random series with this standard deviation would show average decade to decade differences of about 0.24 °C, whereas this series has an average difference of 0.11 °C between adjacent decades. Moreover, since 1915 there have been three adjacent positive values (that is, a warming trend) followed by three successive negative values—a pattern which hints strongly at a dominance of non-random effects.

If we suppose for the moment that a warming trend of 0.1 °C per decade from 1885–1944 followed by a cooling trend of the same magnitude to 1974 represent non-random effects, then the decadal values have a random fluctuation corresponding to a standard deviation of 0·05 °C superimposed on this pattern. This is certainly a minimum value of the 'noise', compounded of instrumental errors and natural fluctuations not taken into account. As most explanations do not account for more than about two-thirds of the variance over the past 100 yr, a better working estimate for the standard deviation of the noise is probably 0.1 °C. This means that there is a 5% chance that the next decade (1975–84) will be ± 0.2 °C or more different from 1965–74 due to 'noise'. Thus, a continuance of, or reversal of, the trend could not reliably be inferred from such a change. If, however, the following decade showed a further 0.1 °C or more movement in the same direction this could be considered as an organised trend with a high probability that it was not due to chance.

From such considerations one could set up three reasonable categories for predictions of the decade centred around AD 2000: (1) 0 3 °C or more above the value for 1965–74, implying a reversal of the cooling trend of the past 30 yr with temperature at least back to that of the optimum in Fig. 1; (2) 0.3 °C or more below the value for 1965–74, implying a continuance of the cooling trend at about the same rate, and (3) within ± 0.3 °C of 1965–74 which implies an expectation of random fluctuations about the value of the latest decade.

Some predictions or quasi-predictions

The published predictions are not always quantified; they tend to say either that the cooling trend will continue or that it will reverse. Among those favouring continued cooling, Lamb has sometimes mentioned a return to the conditions prevailing at the end of the eighteenth century, which would put his forecast in category (2); and Bryson[3] is such an enthusiastic advocate of cooling that his can hardly be put in category (3). Budyko and Vinnikov[4], the most emphatic advocates of a warming, predicted a value for AD 2000 of between 0.5 and 1.0 °C above the latest decade—a prediction clearly in category (1). Mitchell[5] expected that the warming effect of CO_2 and the cooling effect of man-made dust were likely to be in near balance to the end of the century. One might deduce from this that natural fluctuations would determine the sign of the deviation. His expectation could probably be assigned to category (3), but he considers a specific prediction to be unwarranted. Kellogg[6] likewise thinks that we are not in a position to make a categorical forecast: he considers that a warming of 0.5–1.0 °C due to increasing CO_2 is fairly likely by AD 2000, whereas cooling due to man-made aerosol is more doubtful and is likely to be less than this. Thus, he concludes that man's activity will probably raise Northern Hemisphere temperature by some 0.5 °C by the end of the century and natural fluctuations are unlikely to mask this warming trend.

Fig. 1 Decadal means of surface temperature for the Northern Hemisphere, plotted as deviations from the average, 1875–1974 (After Budyko, Willett and Mitchell to 1969; updated to 1974 from Kukla *et al.*[1])

Rationale of the predictions

Budyko and Vinnikov[4] and Bryson[3] interpret the temperature trends over the past 100 yr in terms of the changing transmissivity of the atmosphere. They base this on a Russian time series of direct radiation measurements first assembled by Pivovarova in 1968 and later updated by Budyko and Vinnikov[7]. They are shown in Fig. 2 as deviations in percentage from the average for 1885–1970. The data for the early decades come mainly from Russian observatories but after about 1914 data from American observatories are included. There is an increase of about 4% in direct radiation between the turn of the century and 1940 followed by a decrease of about 6% by the late 1960s. Budyko and Vinnikov[4] and Bryson[3] attribute the increase mainly to the clearing of the atmosphere following the series of violent volcanic eruptions in the 1880s, and the decrease after 1940 to the increased concentration of man-made dust due to industrial activity. From observations of the ratio of scattered to direct radiation at the surface Budyko and Vinnikov[7] conclude that the 4% gain of direct radiation implies a net gain of something under 1% (there is less scattered radiation) which is more than enough to explain the 0.6 °C rise in the Northern Hemisphere temperature over that period.

On the other hand there is considerable doubt whether enough of the volcanic dust ejected into the stratosphere by the Alaskan eruption in 1912 (Katmai)—the last major eruption until the 1950s—would be still present even 10 yr later to depress the temperature noticeably below a clear-air value. Yet about half of the increase in temperature occurred after that date, and Miles and Gildersleeves[8] have argued that this cannot be attributed to the clearing of volcanic dust. Although there is considerable evidence that dust after major eruptions depresses the hemisphere temperature by 0.2–0.3 °C for about 2 yr afterwards, the effect of a single major eruption on the decadal temperature is not likely to exceed 0.15 °C.

The series of major eruptions around the time of Krakatoa (1883) may have depressed the temperature of the 1880s by up to 0.3 °C but after that there has not been a comparable series of eruptions. The Russian series of direct radiation measurements shown in Fig. 2 suggests that the radiation recovered to a normal level after the eruptions of the 1880s, after those of 1902–03 and the Alaskan eruption in 1912. Although there is still some doubt about the response time of the atmosphere, it is likely that the hemispheric temperature returned to near the clear-atmosphere value after each. Thus the depressive effect of these volcanic episodes cannot be considered additive. If this is accepted, then the magnitude of the warming due to the clearance of volcanic dust can hardly be placed higher than 0.3 °C. This leaves most of the warming after 1920 to be explained in some other way and also the 1% increase in direct radiation after 1920. It is probable, however, that the radiation series is not homogeneous, as the number of stations used was increasing with time and it is difficult to be sure that calibrations are the same within 1% over these long periods.

The interpretation of the 6% decrease after 1940 presents further difficulties. First, it has not been demonstrated beyond a doubt[9] that the average atmospheric dust loading of the Northern Hemisphere has increased. The transmissivity at some locations has not changed during this century. It seems very probable that increased industrial activity has put more dust into the lower atmosphere but it seems that the bulk of it falls out within a few hundred kilometres of the entry zone, so that the average increase in tropospheric dust over the whole hemisphere is a very small amount indeed. The reduction in direct radiation shown by the Russian series, if due to man-made dust, is therefore considered to apply only in the neighbourhood of the observatories in Eurasia and North America.

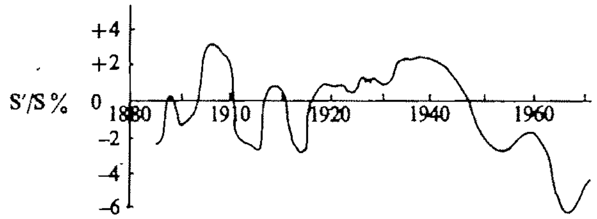

Fig. 2 Five-year means of direct solar radiation anomalies. (From Budyko and Vinnikov[7], based on work by Pivovarova.)

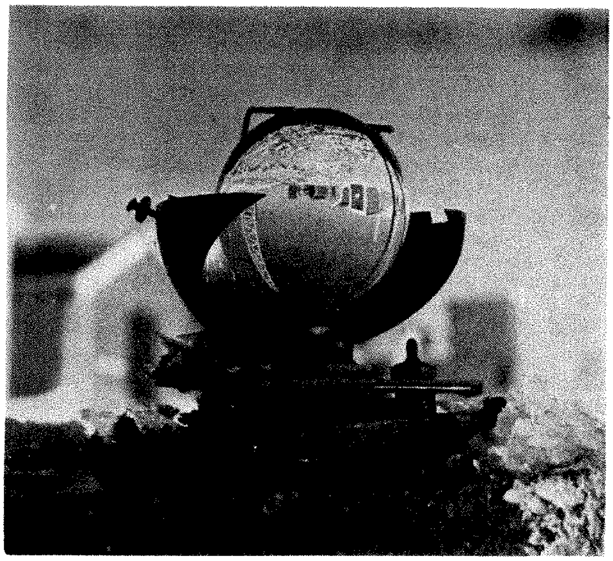
Second, dust absorbs solar radiation as well as scattering it, so that there is a warming effect arising from the absorption of the direct solar radiation. In the case of volcanic dust (in the stratosphere) the warming is confined to the stratosphere but if the bulk of the additional man-made dust is fairly low down in the troposphere this warming could affect the surface temperature. It is uncertain how much this will offset the loss by scattering. Budyko[4] reduces the cooling by one-third and, after making a further allowance for the fact that much of this dust will be below cloud level, concludes that this 6% reduction in direct radiation will cause a temperature reduction of 0.5 °C. This together with a warming of about 0.2 °C—a widely accepted estimate—due to the additional CO_2 gives a net cooling of the right amount. Bryson[3] considers the two effects together and arrives at a net cooling of 0.3 °C. Although the two estimates are in agreement, the uncertainties in reaching them are so great that it is important to explore other ways of assessing whether they are likely.

If the dust absorbs long-wave terrestrial radiation giving a so-called greenhouse effect then the net cooling due to the scattering effect may be very small indeed. Indeed Idso and Brazel[10] have put forward evidence that with realistic concentrations of dust the net effect on the surface temperature would be a warming. Without going this far it seems likely that the surface cooling due to a given concentration of man-made dust in the lower troposphere will be less than that due to the same concentration of volcanic dust in the stratosphere. Mitchell[5] has given estimates of the loading of man-made dust which show that at the end of the 1960s it was about half the estimated average loading of stratospheric volcanic dust in the 1880s. If the depression of Northern Hemisphere temperature below a clear-air equilibrium value for the 1880s could be reliably established, this would give an upper limit to the cooling to be expected from the recent concentration of man-made dust.

Already a divergence of opinion appears. Bryson[3] (and to some extent Budyko[4]), in saying that practically the whole of the 0.6 °C warming from the 1880s to the 1940s is due to the clearing of the volcanic dust, is putting this upper limit at 0.6 °C. Lamb[2] is inclined to the view that other factors were as important in bringing about the warming. It is difficult from the hemispheric temperature data to see how the depressive effect in the 1880s could have exceeded about 0.3 °C and if the effects of the successive eruptions are not additive this would be the upper limit to the cooling effect of the man-made dust in the late 1960s.

Agreeing as they do on the cause of the post-1940 cooling, how is it that Bryson and Budyko then reach such divergent views about the future trend? Bryson regards the cooling since 1940 as showing that the extra opacity due to industrial activity has a larger effect on surface temperature than the reduced emissivity due to the increased CO_2 arising from the same industrial activity. Thus, the expected increase in industrial activity during the rest of this century will bring a steadily decreasing surface temperature. Budyko, however, says that present pollution control measures are reducing the input of dust but not that of CO_2 and that eventually the warming effect of CO_2 will be decisive. He advances two pieces of evidence that this is already happening. The amount of direct solar radiation has, he says, increased since the low values of the 1960s, and the hemispheric temperature has risen by 0.3 °C in the past decade. The reservations concerning the radiation measurements have already been discussed and no other climatologist has claimed to find such a marked increase in temperature for the Northern Hemisphere. Most estimates indicate a reduction of the cooling rate almost to zero in the 1970s but do not show a reversal.



Campbell-Stokes sunshine recorder photographed by W. Scriven, Great Dunn Fell, Westmoreland (now Crown Copyright, Meteorological Office, Bracknell, UK)

Budyko supports his claim for a hemispheric warming by pointing to a warming of about 1.0 °C in the polar regions since the mid-1960s. This polar warming also emerges from an analysis of data from ice flow stations. It reduces the size of the meridional temperature gradient and he claims that in the past a reduction in meridional temperature gradient has been generally associated with an increase in the hemispheric temperature. There has however, been at least one period in the past (1935–44) when the polar temperature was decreasing while that of the hemisphere was increasing, and it would be advisable to have more direct evidence of a hemispheric warming before accepting Budyko's thesis.

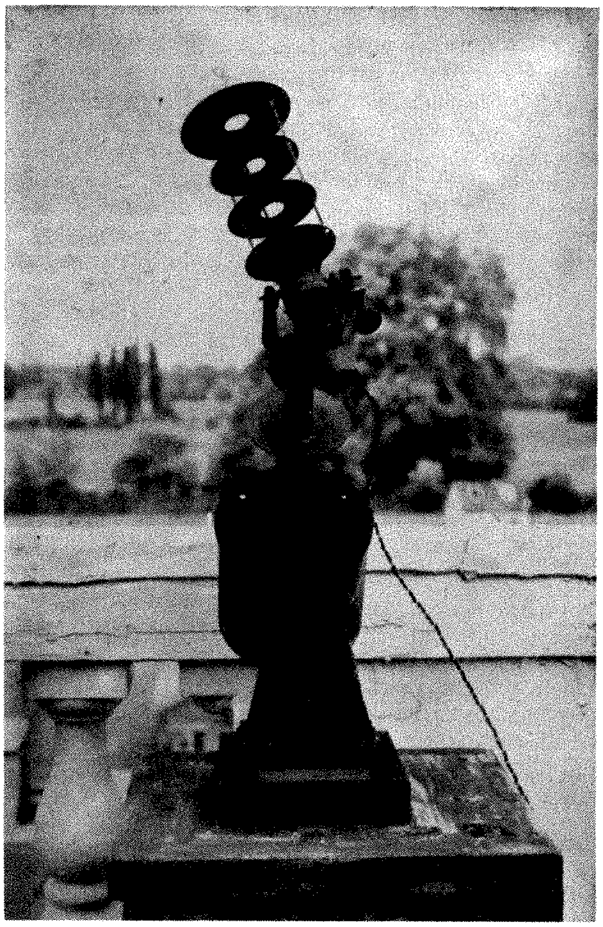
One of the secondary reasons for believing that dust has led to such a substantial cooling since 1940 is that the observed cooling has to be explained in the face of an expectation that the increased CO_2 has increased the equilibrium temperature since the turn of the century by about 0.3 °C. This is widely regarded as the one effect known most precisely but it is not entirely satisfactory to use it as indirect support for the man-made dust case. The net effect of the CO_2 with cloud feedback may be substantially less than this. Besides, if the further increase in temperature after 1920 is neither due to the clearing of volcanic dust nor to the increased CO_2 then a return to the level of the 1920s, if the causative mechanism ceased after 1940, would not be altogether surprising.

There are moreover some grounds for thinking that 0.3 °C is an overestimate of the hemispheric cooling since 1940. Sea temperature data for the tropical Atlantic and Pacific now being analysed in the UK Meteorological Office indicate that temperature increased from a minimum in the 1920s until the early 1960s, and the mean value for the 1960s is probably higher than that for the 1930s. There is some reason to think that the published estimates of Northern Hemisphere temperature (on which the graph in Fig. 1 is based) gave insufficient weight to temperatures in the tropics. If the course of the surface air temperature of the tropics followed that of the sea temperature, then the cooling since 1940 would probably be less than 0.3 °C. This perhaps strengthens the man-made dust case because one of the objections against it is the magnitude of the cooling effect claimed. On the other hand, if pollution control measures are increasing the atmospheric transmissivity as Budyko (and some others) are claiming, then the warming due to increasing CO_2 may more easily balance the cooling effect of dust and even become the dominant effect before the end of the century.

Prediction of some natural fluctuations

If these two man-made effects on climate are likely to be in near balance until the end of the century, this would leave the outcome to be determined by natural fluctuations. These may be due to variations in solar output or planetary albedo (apart from changes due to man-made dust) on the one hand and differences in the amount of heat stored in the oceans arising perhaps from variations in the general wind circulation on the other. Mitchell[5] and Kellogg[6] believe that we are not in a position to predict any of these effects. Some other climatologists are not so cautious and make a prediction of continued cooling based on indirect evidence of a change in solar output associated with long-term variations in the amplitude of the 11-yr sunspot cycle. The number of dark spots on the Sun increases from near zero to a maximum and then back to near zero over a period of about 11 yr. The size of the maximum has varied in the past with a somewhat irregular periodicity of 80–90 yr and there are some grounds for thinking that there is a periodicity of about 180 yr (and perhaps an even longer one). Whether the heat output from the Sun varies with the amount of sunspot activity has not yet been determined definitively. Direct measurements of the solar constant from satellites are not yet adequate to give the answer. Attempts to obtain it from measurements within the atmosphere have likewise failed because corrections for atmospheric turbidity are as large or larger than the changes being looked for and cannot be made with sufficient accuracy.

The views that are held on this matter arise from attempts to relate hemispheric temperature directly to the sunspot number. There seems to be a positive relationship whereby temperature is higher when the sunspot activity is high, but it is a weak relationship with such a low statistical significance that it could



Thermopile for measuring solar radiation (Crown Copyright, Meteorological Office, Bracknell, UK) be a coincidence. As the reliable data on hemisphere temperature extend over little more than one cycle of the 80–90 yr periodicity, this contributes to the uncertainty about the result. There are, moreover, differences in the apparent relationship from epoch to epoch and this is especially notable when we search for the effect in the 300-yr-long temperature record for central England assembled by Manley.

Those who think such analyses nevertheless give a dependable result, that is, higher hemispheric temperatures at the peak of the 80–90 yr cycle, have drawn further support from the analysis of an ice core taken from the Greenland Ice Cap at Camp Century in 1966. This showed prominent cycles at 77 and 177 yr which have been interpreted as being forced by the sunspot variations. The value of this as independent evidence is weakened by the difficulty of constructing the depth/time scale for the ice core and the admission that in this construction an effort was made to preserve natural climatic fluctuations of these lengths, that is, by assuming what we are trying to prove.

The sunspot activity in fact increased with each cycle from 1900, reached a high value in the cycle 1954–64 and fell considerably in the next cycle. It seems a reasonable extrapolation of past solar behaviour to expect the remaining two cycles of this century to show further reductions, and on the basis of the above relationship a number of forecasts of a cooling trend have been made. The proponents of these views rarely state what amplitude the Sun-linked cycles may have. The optimum fit of central England temperature data for spring, summer and autumn—the seasons with the best correlation between temperature and sunspot numbers—for a cycle of 88 yr (that is, eight 11-yr sunspot cycles) gives an amplitude of 0.13 °C which is barely above the noise for this data. Accepting this and placing the maximum in the 1954–64 cycle we should expect the coolest 11-yr period (cycle 1997–2007) to have a temperature 0.26 °C below that of 1954–64. This is for central England data which has in the past displayed variations with nearly twice the amplitude of the Northern Hemisphere data. The amount of depression of hemisphere temperature at the minimum of this cycle around AD 2000 would seem to be at most 0.15 °C. This is just about the amount of cooling between the decades 1955–64 and 1965–74, and would not in any case justify an unambiguous forecast in category (2), that is, a continuance of the cooling trend.

What do we know of the effect of changes in the large-scale circulation on the cloud cover or the distribution of heat between ocean and atmosphere? At present we neither have the knowledge nor the data to know precisely what these changes have been in the past. The intensity of the circulation seems to have been significantly higher during the warming period (1900–40) than in the subsequent years of decreasing temperature. The association of the warming of the Russian Arctic with the increased circulation on the North Atlantic also points to a positive association of circulation strength with hemisphere temperature. The correlation coefficient of 5-yr means of the surface westerlies of middle latitude and hemisphere temperature is, however, not above the chance level. The low correlation arises because the former peaked in the decade 1920–29 and the latter at least 20 yr later. The correlation with the temperature lagging 20 yr is statistically significant but it is not easy to find a satisfactory physical explanation for a lag of this amount. Even if we accept that there is a real association between circulation strength and temperature we need to be able to predict the former to exploit it in a temperature forecast. There is no adequate explanation of the high level of the circulation in the period 1900–40. Some Russian climatologists, among them Vitels (see Lamb[2]), have claimed that the strength of the mid-latitude westerlies is positively related to the long-period sunspot activity. The correlations, however, fall in the range where they could be coincidence especially as the circulation data cover only one cycle.

In an attempt to overcome this difficulty Lamb[2] has assembled data on the frequency of surface south-westerly winds at London going back to 1340 and, assuming these to parallel the strength of the general circulation, has proposed that there is a 200 yr cycle in its strength. On this basis the decline in circulation since 1940 may be expected to continue to the end of this century and beyond. Supposing this to be correct a positive relationship with temperature would then indicate a continued cooling.

Accepting for the moment that the series of south-westerly wind frequencies is homogeneous over the three centuries, there is still the need to show that their frequency is a good measure of the strength of the general circulation. Lamb[2] has not established this beyond a doubt but there looks to be a strong likelihood that this is the case. The next step, that is, establishing a 200-yr cycle, is done less satisfactorily. The argument from the surface wind data seems to rest on the occurrence of times of rapid decline in frequency at intervals of 200 yr from the middle of the sixteenth century to about 1960: this would perhaps establish a saw-toothed highly asymmetrically profile but would seem to leave an uncertainty about further detail in the bulk of each 200-yr period. He adduces evidence of a 200-yr oscillation in solar output as a forcing factor for this putative cycle in the circulation intensity. This evidence comes from variations in ^{14}C concentration thought to be due to variations in the corpuscular and far ultraviolet part of the solar output, the effect of which on the tropospheric circulation has not been satisfactorily established.

Summary of situation

The man-made changes in CO_2 concentration and dust seem to offer the clearest indication of the future trend of temperature. However, the need to explain a cooling over the past three decades in the face of an expected warming due to the additional CO_2 has tended to lead to an exaggeration of the cooling effect of volcanic dust and perhaps even more that of man-made dust. There is also a considerable doubt about how much extra optically effective dust there is on a global basis.

Inasmuch as there is still some doubt about the cause of the bulk of the warming after 1920, a considerable element of uncertainty is introduced into prediction. If the warming was a complicated end-effect of the enhanced circulation during 1900–40 resulting in a reduction in the area of Arctic pack ice and a consequently higher equilibrium temperature due to a reduced albedo, then the post-1940 cooling may be an effect of the reduced circulation. Up to the 1970s, however, it has not been accompanied by a return of Arctic ice to the higher values prevailing at the turn of the century, so that the equilibrium temperature arising from the ice-albedo contribution is probably still well above that around 1900. Does this mean that the full effect of the reduced circulation has not yet been reached? In this connection the failure to explain the lag of temperature behind the circulation is yet another example of how failure to explain the past temperature changes renders prediction hazardous.

In the absence of an explanation based on a consistent theory of climate, prediction would only be reliable if there were some strong and dominant periodic effects. Despite years of search for these and many confident claims of success, none of them stands up well to critical scrutiny. In these circumstances therefore only a great external pressure to make a categorical forecast or an undue attachment to one set of data and its interpretation would seem to explain the abandonment of an agnostic position, or at most the expression of a very cautious probability forecast.

Vertical particulate spires or walls within the Florida Current and near the Antilles Current

John R. Proni, Fred C. Newman, Feodor Ostapoff & Donald J. Walter

National Oceanic and Atmospheric Administration, Atlantic Oceanographic and Meteorological Laboratories,
Ocean Acoustics, Miami, Florida 33149

Spires or humps of particulate material extending from the bottom of the oceanic mixed layer to near the ocean's surface have been observed in the Florida Current and in the regions of other current systems, using an ultrasensitive, 20-kHz acoustical echo sounding system. These spires may be the result of oceanic circulation rather than a purely biological phenomenon.

ACOUSTIC observations of spires of particulate matter extending from the bottom of the mixed layer to near the surface of the ocean have been made in the Florida Current (November 1977), in the region of the Antilles Current (January 1973) and in the Caribbean (April 1978). The Florida Current observations were made in the vicinity of 80° W long, and in latitudes between 25 and 28° N; Antilles Current region observations were made in around 70° W long, 25° N lat, and the Caribbean observations were made in a region ~200 nm north of Caracas, Venezuela. The observations were made using an ultrasensitive, short pulse length (<1 ms), towed, narrow beam (18°), 20 kHz acoustic echo sounding system. The use of this system to detect layers of particulate matter and internal waves in the ocean has previously been documented[1,2]. The acoustical frequency (20 kHz) and receiver sensitivity are such that scattering from oceanic turbulence or density gradients is not detectable, so that particulates and/or biota are the most likely sound scatterers detected.

Acoustic and XBT data

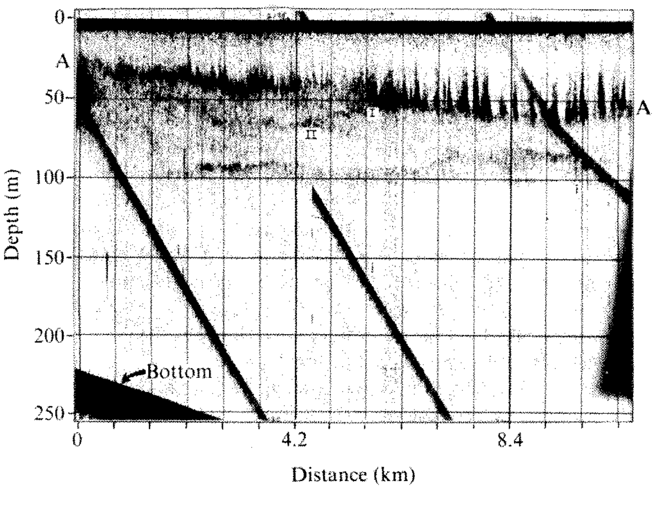
Figure 1 shows real-time acoustic data obtained from the RV Researcher while crossing the Gulf Stream off Palm Beach, Florida. The ship proceeded due east from Palm Beach, at a speed of 2 m s^{-1} beginning in water of depth 220 m. A layer of particulate matter corresponding to the depth of the bottom of the mixed layer may be seen gradually descending spatially from left to right (labelled A in Fig. 1). Lines of constant density (isopycnals) are known to slope down proceeding from west to east across the Gulf Stream[3]. The slope of the reflecting layer has a value $\sim 4\times10^{-3}$ which compares favourably with the 3×10^{-3} isopycnal slope, a value deducible from the isopycnal data of Schmitz and Richardson[3]. Interference lines generated by the Researcher's echo sounder are indicated and should be disregarded.

The most interesting features are the spires of particulate material which are seen to extend vertically from the particulate layer corresponding to the bottom of the mixed layer. Figure 1 shows that the spires eventually disappear in a shorewards direction; the mean horizontal spacing of the spires is ~200 m. Spire widths at the base of a spire seem to be 100 m or more. An important characteristic of the acoustical system used in gathering the data presented in Fig. 1, is that it was not designed for obtaining data near the ocean's surface, say, within 10 m. Accordingly, information or acoustical signals coming from this region is suppressed by the electronics. Thus it is uncertain whether the particulate spires observed in Fig. 1 reach the ocean surface.

Expendable bathythermograph (XBT) records were gathered at the same time as for the acoustic data. Three XBT records taken at 21.30, 21.45, and 22.00 LT, are shown in Fig. 2. Note that the temperature profiles are essentially featureless down to the depth of the acoustic reflecting layer, at which depth small temperature gradients are visible. Previous experience[4-6] has shown that a particulate layer is often observed in coincidence with a temperature gradient. In addition to the shallowest temperature gradient (clearly visible at 45 m), the temperature profile gathered at 21.45 LT has two small temperature gradients (I and II in Fig. 2; with the corresponding reflecting layers marked I and II in Fig. 1).

From the data of Schmitz and Richardson[3], it is reasonable to expect that the northwards surface current varies from ~100 cm s^{-1} at the left of Fig. 1, to ~180 cm s^{-1} at the right of

Fig. 1 Acoustic reflecting layers and particulate columns observed while crossing the Gulf Stream: interference lines are labelled (i).



0028-0836/78/0276—0360$01.00

Fig. 1. The mean eastwards current is very small, being maximum at the right of Fig. 1, with a magnitude no larger than $\sim 5\ \text{cm s}^{-1}$.

The acoustical data shown in Fig. 1 are greatly exaggerated in the vertical; Fig. 3 is a geometrically corrected interpretation of the data between the 7.7 and 8.8 km range limits of Fig. 1. Figure 3 shows that what we are calling spires, because of their appearance of the acoustic records, are in fact more like humps or mounds. 'Hump' may not be an adequate description, however, because the along-stream extent of a particular hump may greatly exceed its cross-stream extent; in which case perhaps the term 'wall' would be more appropriate. There is acoustical evidence that the along-stream length of a hump or spire could be >1 km.

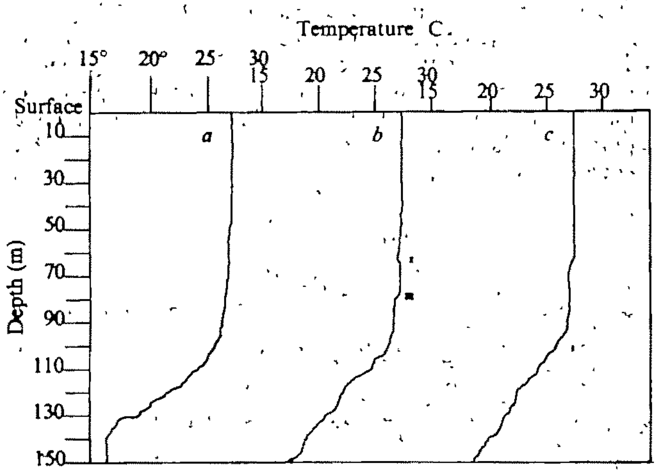


Fig. 2 Temperature profiles corresponding to the acoustic data in Fig. 1. *a*, T-11-38, 21.25LT; *b*, T-11-39, 21.43LT; *c*, T-11-40, 22.05LT.

Vertical structures

We can be certain that the vertical structures were observed in each cross-stream traverse made by the ship between longitude 28 and 25° N, but whether given spires in a crossing along-stream are continuations of given spires in another traverse is not.

The columns shown in Fig. 1 have a vertical extent, L, which is of the order of the depth of the bottom of the mixed layer, that is, if d is the depth of the bottom of the mixed layer, then

$$L \sim d \tag{1}$$

The spires have a horizontal spacing, h, which on average seems to be ~2–4 times the depth of the mixed layer:

$$2d \leq h \leq 4d \tag{2}$$

This conclusion is reached by examining substantial additional data to that shown in Fig. 1. Not all the spires are of equal size and dimensions; equation (2) is an average statement and implies that as the depth of the thermocline changes, as occurs in traversing the Gulf Stream, so too should N (the number of spires per unit horizontal distance) vary:

$$\frac{1}{4d} \geq N \geq \frac{1}{2d} \tag{3}$$

The spire width, w, at the spire base in the cross-stream direction is of the order of 2–5 times the mixed layer depth:

$$2d \leq w \leq 5d \tag{4}$$

A typical dimension for d is 50 m, so that $L = 50$ m, $100\ \text{m} \leq h \leq 200\ \text{m}$, $0.005\ \text{m}^{-1} \leq N \leq 0.01\ \text{m}^{-1}$, and $100\ \text{m} \leq w \leq 250\ \text{m}$. The spire structures persist over a 24-h period and are not changed due to the rise of the deep scattering layer (DSL). In fact, the DSL rises to the thermocline depth and then contributes (for example, biota) to the particulate spires.

Table 1 Data from observations of vertical particulate spires

Date	Location	Time interval of observation	Wind speed (m s^{-1})	Wind direction
19 Mar. 1978	14°12′ N 66°39.0′ W	20.56–22.06 LT	10	090°

14 Nov. 1977	26°49.3′ N 79°54.1′ W	21.00–23.30 LT	7	065–085°
31 Jan. 1973	25°21.8′ N 71°12.2′ W	11.35 LT	10	080°

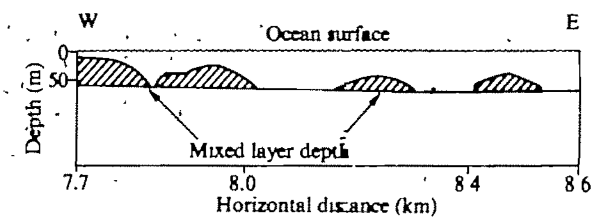
As we have stated, we are uncertain about the phenomena generating and sustaining the particulate spires. However, the hypothesis for the origin of the spires (or, perhaps walls) has two parts. First, the spires are not primarily the result of biological behaviour. The particulates comprising the reflecting layer, out of which the spires extend, are thought to be plankton, and in the case of the Florida Current, at least, are also thought to be sediment, perhaps in combination with biota. It is unlikely that such particulates are highly mobile, and, in any case, there is no report of innate particulate spire-forming behaviour for oceanic marine biota. Second, the spires arise from oceanic water circulation and congregate in spires (or walls) as a result of that circulation.

Water circulation

If the particulate structures arise from water circulation, what would be the form of that circulation? The structures might be formed by an upwards directed flow so that the particulates are carried upwards from the reflecting layer. If there is such a vertically directed flow, then only the uppermost reflecting layer contributes particulates to the flow. This can be seen by examining some of the deeper reflecting layers in Figs 1 and 4. No particulate spires extend from any other than the shallowest reflecting layer which suggests that the vertical flow is confined between the thermocline and the surface.

We feel that the proposed circulation is not due to the presence of internal waves. As may be seen from Figs 1 or 3, little or no vertical spatial variation of the shallowest reflecting layer appears on the 50–500 m length scale. Internal waves of this horizontal scale, of amplitude as small as a couple of metres, are detectable with this acoustic system[2]. However, small scale perturbations are visible on some of the deeper reflecting layers in Fig. 4. The kind of wind conditions at the time the spire observations were made may be relevant to whether circulation cells of some type are present. For example, Faller[7] has shown that certain wind and wave conditions must be present for Langmuir type circulations to occur. Table 1 shows wind and other data for various spire observations: such as measured winds exceed $5\ \text{m s}^{-1}$ in all observations. This contradicts the

Fig. 3 Interpretation of the acoustic data in Fig. 1 from 7.7 to 8 km with the vertical exaggeration removed.



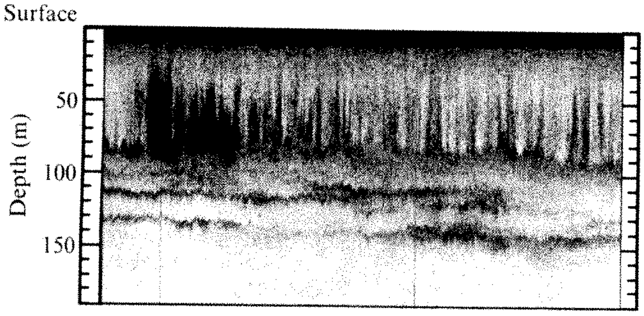


Fig. 4 Acoustic reflecting layers and spires in the area of the Antilles Current.

results reported in ref. 8: in which it is stated that the "columnar scattering" is observed in the wind mixed layer during very calm weather conditions. Table 1 also indicates that observations of spires were made during daylight and night-time conditions. We do not wish to speculate any further, questions as to whether the flows are some sort of circulation cells (so-called Langmuir cells) must be put off for the moment.

Implications of particulate spires in the Gulf Stream

One of the most important implications of the existence of particulate spires in the Gulf Stream is the small scale variability in the horizontal of particulate densities. Figure 1 shows the small scale variability of particulate densities, both in the vertical and the horizontal. While on-station, the particulate columns have the appearance of patches as the ship slowly drifts. Depending on the along-stream length of the cells, there may be a distinct difference in a biological net tow, depending on whether the tow is along-stream or cross-stream. The behaviour in the deep scattering layer, mentioned above, is interesting in that the DSL is generally thought to be mobile, but, nevertheless, preferentially aligned above the thermocline into the spires.

There are also some interesting potential implications for ocean-mixed layer studies; particularly if spire formation indicates an underlying circulation. As Pollard[9] pointed out, circulations such as those of Langmuir are potentially efficient in mixed layer momentum redistribution. A major question remains: how widespread or typical are the phenomena described here? We do not know, for example, if such spires are in some way related to the presence of ocean currents. The data gathered in Fig. 1 were clearly in a current system—the Gulf Stream. The observations shown in Fig. 4 may have been of a less well known current system[10].

Conclusion

Spires of particulate matter have been observed extending from the bottom of the mixed layer to near the surface of the ocean and in the region of different ocean current systems. The detection of the spires was made possible through the use of an ultrasensitive 20 kHz acoustical system. Further research is required into the nature of the particulates present and of the phenomena generating the spires.

Protein disk of tobacco mosaic virus at 2.8 Å resolution showing the interactions within and between subunits

A. C. Bloomer, J. N. Champness*, G. Bricogne, R. Staden & A. Klug
MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

Protein subunits in the two layers of the disk of tobacco mosaic virus have very similar conformations. Much of the bonding between subunits is polar, including salt-bridge systems. Arginine residues play a prominent part here and elsewhere. Interactions within each layer involve groups whose contacts can be adjusted to allow the transition from disk to virus helix. Aromatic clusters within each molecule are linked in a hydrophobic girdle encircling each ring.

THE disk of tobacco mosaic virus (TMV) protein (see review by Caspar[1]), is an obligatory intermediate in the assembly of the virus from its constituent RNA and protein[2]. It fulfils both the physical requirement for nucleating particle growth and the biological requirement for specific recognition of the viral RNA. The disk is composed of two rings or layers, each containing 17 subunits[3] and both facing the same way[4]. The two layers are in contact only at high radius whereas at the opposite end of a subunit, towards the central hole of the disk, they are separated as if poised for reaction with, and intercalation of, the viral RNA[5]. Assembly is initiated by insertion into the middle of the disk[6] of a special sequence within the RNA[7] which folds into a hairpin loop[8]. Interaction with this loop has several consequences for the protein subunits: the circular subunit arrangement of the disk becomes the helical one of the virus; the two rings close about the bound RNA, losing the pairing interaction between them at high radius; the flexible part of the protein at low radius assumes the ordered structure of the virus[9]. During these rearrangements all the lateral contacts between subunits are essentially preserved while the axial ones are completely changed.

We have previously described[5], at 5 Å resolution, the subunit packing within the disk and the folding of the polypeptide chain. Extension of the analysis to 2.8 Å resolution provides details, as described here, of the conformation of the subunits and the variety of their interactions. Subunits in the two layers are remarkably similar despite their crystallographic independence. Notable features of the structure include the important structural roles of several arginine residues, the extended salt-bridge

Mean isomorphous difference $\langle\lvert F_{\mathrm{nat}}-F_{\mathrm{der}}\rvert\rangle/\langle F_{\mathrm{der}}\rangle$	—	0.30

Using the methods of oscillation photography[13], with a range of 0.5–0.75° for a single picture, a total of about 230 film packs were used to cover the complete 90° oscillation range about the *b* axis, and the 32° of cusp data about the *a* axis, which together constitute a complete set of data. A typical film pack required an X-ray exposure of about 10 h. The crystal lifetimes varied widely up to a maximum of about 50 h exposure for any one location, with translation of the crystal giving up to three locations per crystal. Overlapping rotation ranges were used whenever the crystal location was changed. The fully and partially recorded intensities were measured with a flat-bed hybrid densitometer[14]. Films were scaled together by means of symmetry-related reflections recorded on different films and a symmetry *R* factor was computed for each compiled set of data. Reflections split between two contiguous rotation ranges were not used for scaling but are included in the statistics They comprise 40% of the total measured reflections and are not quite as accurate as comparable fully recorded reflections, but the compiled sets of data would have been far less complete without them.

networks both within and between the rings, and the encircling of each ring by a complete girdle of hydrophobic residues.

Structure analysis

Preparation and crystallisation of the disk protein have been described previously[10]. The crystals are orthorhombic, space group $P22_12_1$, with unit cell dimensions $a = 228$ Å, $b = 224$ Å, $c = 174$ Å. There is one disk of molecular weight 600,000 per asymmetric unit[11] with its 17-fold axis approximately parallel to *c* (ref. 12).

X-ray intensities were recorded by an extension of the methods of oscillation photography[13] used for the 5 Å data and described elsewhere[5]. Almost 2×10^6 intensities were measured[14] for crystals of the native protein and a single covalently bound mercury derivative[10] (Table 1). The derivative crystals did not diffract as well at higher resolution as those of the native protein, and thus the mercury data effectively extend only to the slightly lower resolution of 2.95 Å. This was compensated for by use of the 17-fold non-crystallographic symmetry[11,12] to extend, as well as improve, the phases from the single-isomorphous derivative. Heavy-atom parameters were refined independently for the 34 mercury atoms in a manner similar to that used at 5 Å resolution[5]. Details of these calculations will be published elsewhere. Phase refinement by non-crystallographic symmetry averaging[15–17] proceeded in two stages (Table 2) to investigate the existence of any departures from the 17-fold symmetry. However, no such departures were found. The averaged map resulting from stage I of this phase refinement (cycle 2 map, 1976) was used in an optical comparator[18] to build an atomic model of the protein subunit which was verified by the cycle 5 map (1977) from stage II of the refinement. This map was used both for making minor adjustments to the physical model and for model-building with a computer-graphics program (BILDER)[19]. All the atomic coordinates used in the figures accompanying this paper are taken from this computer model. Parts of the model are shown in Fig. 1 superimposed on the cycle 5 electron-density map.

Description of the subunit

The molecular boundary, the course of the polypeptide chain and the strong similarity between subunits in the two rings, which were clear at 5 Å resolution, are all confirmed at higher resolution. The chain-tracing shown in Fig. 2 differs from that based on the 5 Å map only in that the wrong alternative was then chosen for the connectivity of the four-way contact at 70 Å radial distance from the centre of the disk. In no way does this affect the sequence of the four main helices, the only consequence being to reverse the direction of the chain through the 'hanging loop' from that proposed earlier.

Detailed interpretation of the map has led to an atomic model of a subunit in the B ring of the disk and all its contacts with neighbouring molecules. The densities for a subunit in the two rings of the disk are so similar that any differences in molecular conformation between the rings will be assessable only after refinement of the molecular coordinates, which is now in progress, has been completed. Examination with a computer-graphics program[19] of the model for a subunit in ring B superimposed, by a rigid-body transformation, on the density for a ring A subunit showed that the atoms in the main chain were all within 0.5 Å of the positions indicated by the density and that most of the side chains were equally close.

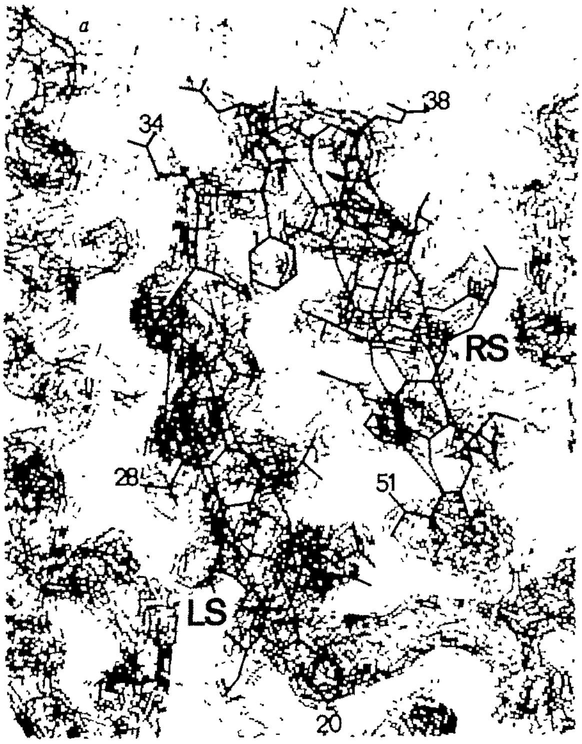
Table 2 Progress of the phase determination

	Stage I			Stage II			
Cycle	0	1	2	2*	3	4	5
*R factor after averaging		0.47	0.29	0.41	0.37	0.31	0.28
Correlation (between F_{obs} and F_{calc})		0.63	0.85	0.69	0.75	0.82	0.86
Figure of merit	0.48	0.63	0.78	—	—	—	—
Mean phase change from last cycle		41°	11°	41°	37°	13°	7°

*$R = \langle\lvert F_{\mathrm{obs}}-F_{\mathrm{calc}}\rvert\rangle/\langle F_{\mathrm{obs}}\rangle$. Where F_{calc} is the structure factor computed from the averaged map.

The initial data set consisted of 145,000 amplitudes phased by single isomorphous replacement (SIR) with a mean figure of merit of 0.48, and of 55,000 unphased amplitudes, mostly between 3 2 and 2.8 Å resolution. Heavy-atom parameters had been refined independently for the 34 mercury sites. The parameters of the 17-fold non-crystallographic symmetry axis were then checked but found to be unchanged from those determined at 5 Å resolution. The phase refinement was done in two stages, to settle any doubt as to whether the absence of density at low radius in the 5 Å map was due to disorder or to an abuse of 17-fold averaging. For stage I the electron density was averaged only in that region of the disk lying between 40 and 90 Å radius, and was left unchanged in the rest of the asymmetric unit. This considerably weakened the phase constraints imposed by the symmetry, as the *U*/*V* ratio[16] was 0.6, but combination of phase information from SIR and from this partial averaging still acted as a constraint, and produced a marked improvement in the overall quality of the map. However, no significant departures from 17-fold symmetry could be detected, either at low radius or at contacts between adjacent disks. These unconstrained regions were rather noisy, and this noise tended to correlate with itself from one cycle to the next, leading to spuriously low residual *R* factors. For stage II, the density was 17-fold averaged in the whole disk at all radii above 20 Å, and was reset to its average value outside the disk boundaries. Deep holes of negative density at the heavy-atom sites, due to poor SIR parameters, were removed from the maps. The phases calculated from such maps were associated directly with the observed amplitudes, without weighting and without recombination with the isomorphous phases, to produce the structure factors used in the next cycle. The use of this new procedure, starting from the phases of cycle 2, induced a large readjustment of the poorer phases (cycle 2*), followed by convergence. The constraints imposed by the 17-fold symmetry were 13.5 times as strong ($U/V = 0.045$) as in stage I, yet a comparably low residual factor was obtained. This strongly suggests that all the ordered density in the disk accurately obeys the 17-fold symmetry.

The central part of the molecule consists of a group of four α helices which are arranged closely parallel or anti-parallel to each other and extend between 45 and 65 Å radius[5]. The left and right slewed helices, LS and RS, in the upper half of the subunit are joined at the end proximal to the disk axis by a short bend in the protein backbone referred to as the slewed hairpin. The right and left radial helices, RR and LR, in the lower half of the subunit both fade into weak discontinuous density, indicative of the flexibility of this loop region of the protein in the



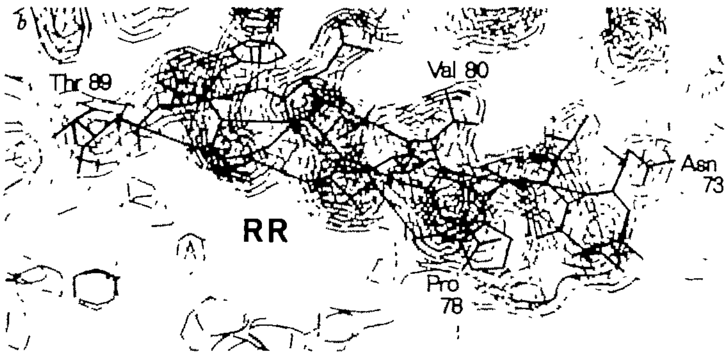


Fig. 1 The electron-density map (cycle 5) for three of the helical regions of the structure with the model superimposed. For continuity, the atomic skeleton is shown over a greater depth than the map. This is contoured at equal intervals of 0.12 e Å^{-3} above zero with the F(000) term excluded. *a*, A slab 6.5 Å thick through the two slewed helices and their connecting hairpin loop, viewed from above. The left slewed helix LS begins at Pro 20 and terminates with a bifurcated hydrogen bond from the peptide NH of residue 33 to the carbonyl groups of residues 29 and 30 which are in the α- and 3_{10}-helical positions, respectively. The right slewed helix RS terminates in similar fashion, with the carbonyl groups of residues 47 and 48 sharing the hydrogen from the peptide nitrogen of residue 51. The RS helix begins with a hydrogen bond from the hydroxyl of Thr 37 to the peptide NH of residue 40. The loop connecting the helices includes Glu 34 which forms an inter-subunit hydrogen bond with Thr 42, Phe 35 which points back into the hairpin between the two helices, and three invariant residues Glu 36, Thr 37 and Glu 38 which all point inwards towards low radius where they are exposed to the solvent. *b*, A slab 5 Å thick through the right radial helix RR, viewed from the side, showing Pro 78 contained within this helix which starts at residue 74 with a bifurcated hydrogen bond from the peptide carbonyl of 73. The proline prevents the formation of two potential hydrogen bonds within the helix, those which would have involved the NH groups of residues 78 and 79, and causes the helix axis to become more closely horizontal at higher radius. The two peptides whose carbonyl groups are unable to form hydrogen bonds are tilted away from the regular helical conformation, exposing them to the solvent. The helix continues to Asp 88 where the density then becomes very faint, with Thr 89 probably not in a helical conformation but only weakly indicated in this map.

absence of RNA[5]. The flexible loop which connects these radial helices at their proximal ends is, in the virus, located at lower radius than any other part of the protein[9]. The distal ends of all four helices are braced together by a short anti-parallel β sheet of four strands. Amino acid side chains on the high-radius side of this sheet form part of a hydrophobic girdle which extends continuously around the circumference from one subunit to the next. The girdle also includes residues from the upper loop, a piece of extended chain between residues 54 and 67, joining the RS and RR helices, the hanging loop extending from the N terminus towards residue 16 of the β sheet and the RS helix, and the C-terminus region arising from the β bend at the end of the LR helix. Within this girdle is an extended aromatic cluster in the centre of each subunit and a smaller such cluster across the subunit interface. Elsewhere in this interface and that between the two layers, there are systems of salt bridges involving some of the many arginine residues present in TMV protein. Arginine residues play an important part in both intra- and inter-subunit interactions, exploiting fully the high specificity and high directionality of the bonds which can be formed. These various elements of the structure will be considered in turn.

The α-helical core and the β sheet

The four main α helices include about 60 residues out of the total of 158 (ref. 20), with residues 20–32, 38–48, 74–88 and 114–134 occurring in the LS, RS, RR and LR helices, respectively. Residues 49–52 form a 3_{10}-helical extension of RS at its distal end. All the helices are somewhat distorted from the idealised structures. The helices are packed as in a segment of a left-handed, 4-stranded supercoiled bundle with hydrophobic contacts along the centre. This hydrophobic core contrasts with the many polar and charged groups on the outside of the supercoil where there are alternating patches of polar and hydrophobic residues. The ends of the helices are orthodox, with bifurcated hydrogen bonds finishing off both LS and RS (Fig. 1*a*) and starting off RR (Fig. 1*b*), a hydrogen bond from a side chain at the beginning of RS and a β bend at the end of LR. Whereas Pro 20 starts the LS helix in the usual manner, the position of Pro 78 within the RR helix is highly unusual. The proline distorts the helix, causing its axis to incline more steeply upwards towards lower radius, thereby preventing the formation of two of the helical hydrogen bonds (Fig. 1*b*).

The hairpin bend joining the slewed helices contains the highly conserved group of residues 33–38. Phe 35 extends back inside the hairpin with its aromatic ring between the pair of helices in a similar manner to the packing observed in myoglobin of Phe 123 between the G and H helices[21]. Invariant glutamines 36 and 38 extend inwards towards low radius, suggesting an availability for interaction with nucleic acid. Other residues in this loop form bonds to the lower half of the subunit. The flexible loop of residues 89–113 connecting the radial helices is ordered only in the presence of RNA and so the map has no interpretable density at 20–40 Å radius, where these residues would be expected, and only weak density for residues 114–116 in the LR helix. When the mobility of the loop[22] is reduced by nucleotide binding to the disk, it seems, as discussed below, that the LR helix begins properly at residue 109 or 110. The RR helix terminates abruptly after Asp 88, which forms an inter-subunit salt bridge with Arg 122.

The distal ends of the four helices are connected transversely by a narrow and twisted strip of β sheet shown schematically in Fig. 3. The four main strands of the sheet tie the helices together in pairwise fashion with the two slewed helices above linked to the upper two strands of the sheet and the two radial helices below to the lower strands. The two central strands of the β strip are themselves connected through the high-radius upper loop. This loop and the other connecting loops in the sequence do have some very short helical segments (α and 3_{10}) but few of these are long enough to have even a single helical hydrogen bond.

The hydrophobic girdle

The central part of each subunit on the distal side of the β sheet is a cluster of aromatic residues: Trp 17, Tyr 70 and Tyr 139 from the sheet, Phe 12 and Phe 144 from the two terminal loops, and Phe 62 from the upper loop. These groups, together with Pro 56 and Pro 63, form an extended cluster in which the rings are mostly in an edge-to-face arrangement. At the same radius of 75 Å, but extending across the molecular interface, there is a further cluster composed of Pro 20 and Phe 67 with Pro 7 and Phe 10 of the neighbouring molecule. These two clusters are joined by several hydrophobic aliphatic side chains, arising from elements of all four chains which cross this radius, to give a continuous belt of hydrophobic interactions encircling each ring of the disk.

Salt-bridge systems

The subunits in the two layers have three regions of interaction (Fig. 4) of which the largest is the extended salt-bridge system shown in Fig. 5. This involves the only two lysine residues and four acidic groups, from three segments of the main chain in the lower ring with Asn 127, Glu 131 and Arg 134 from the LR helix in the upper ring. Almost all the possible hydrogen-bonding capabilities are utilised in this complex 3-dimensional network, in which two water molecules also participate. Note that the disk is stable in very high ionic strengths[23,24], so that a simple view of the instability, in high ionic strengths, of isolated salt bridges does not apply to an extended system like this with hindered access to solvent.

Adjacent subunits within a ring are linked at low radius by a simpler salt-bridge system involving Arg 122 and Asp 88. In this case also, most of the hydrogen-bonding potential of the arginine is utilised, with additional links to Thr 89 in the neighbouring subunit and to the peptide carbonyl groups of residues 31 and 33 in the same subunit.

At higher radius in the same molecular interface (Fig. 2), the region of polar interaction has an intra-subunit salt link involving Arg 71 and Asp 77 with additional hydrogen bonds to Thr 81, Ser 49, and an inter-subunit link to Thr 28. In the cowpea strain of the virus, however, coordinated sequence changes[25] result in this region also having an inter-subunit salt linkage.

Role of arginine residues

The basic residues in TMV comprise 2 lysine, 11 arginine and no histidine residues[20]. The role of the lysine residues and three arginine residues (134, 122 and 71) in various salt-bridge systems of interaction within the subunit interfaces has been discussed above. In the subunit itself there are also two simple salt linkages involving Arg 141 with Asp 64 and the invariant pair Arg 61 with Glu 145. Both these pairs are exposed on the outer circumference of the disk where they link the C-terminal and upper loops of the protein.

Interaction with RNA is expected to involve three arginine residues[1] out of the four invariants (41, 90, 92, 113) which occur at low radius. Arg 41, the only such residue seen in our map, seems less likely to have such an interaction than the other three whose positions, as extrapolated by model-building from positions 89 and 114, would have them all pointing down from the A ring into the 'jaws' between the layers of the disk.

The high specificity and directionality of the polar bonds formed by arginine residues contrast with the hydrophobic surfaces presented by their methylene chains. That of Arg 61 lies against the planar face of Trp 152, and similarly Arg 122 is close to Leu 31, and Arg 41 lies between the rings of Phe 35 and Phe 87.

Inter-subunit contacts

Contacts between the layers: Three regions of contact are indicated in Fig. 4, all of different type and all occurring at the higher-radius end of the molecule but spaced apart. The outermost is a polar interaction between serines 147 and 148 and Thr 59. At lower radius are the extended salt-bridge system described above and also a small hydrophobic patch where Ala 74 and Val 75 both touch the ring of Pro 54. These three contacts form an essentially kinematic mounting of a subunit of

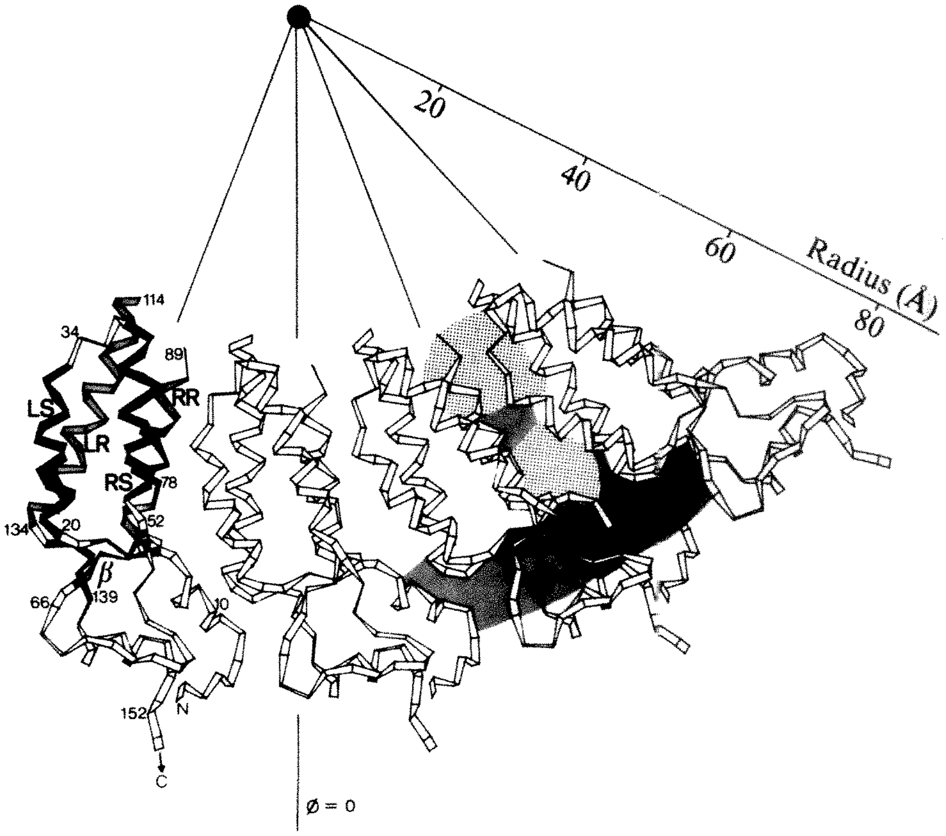

Fig. 2 The folding of the polypeptide chain and the lateral interactions between subunits. Four adjacent subunits within a ring are shown viewed from above. The N and C termini of the chain are marked on the extreme left subunit together with the four main helices, left and right slewed (LS and RS) in the upper half of the molecule with right and left radial (RR and LR) below, and the β sheet which connects all four helices at their higher radius ends. The other subunits show the overall shape of the subunit as a scimitar, with a pronounced slew relative to the radius of the ring. The interface contains alternating patches of polar residues, indicated by stippling, and of hydrophobic residues, indicated by solid shading, which are all contributed to by residues from both the subunits forming the interface. The hydrophobic patch at higher radius is continuous with the hydrophobic girdle which extends circumferentially across the whole width of a subunit and across the interface, forming a continuous belt around the ring. The hydrophobic girdle includes residues from the high radius side of the β sheet, the upper loop which joins the RS and RR helices and the two lower loops leading to the termini of the chain.

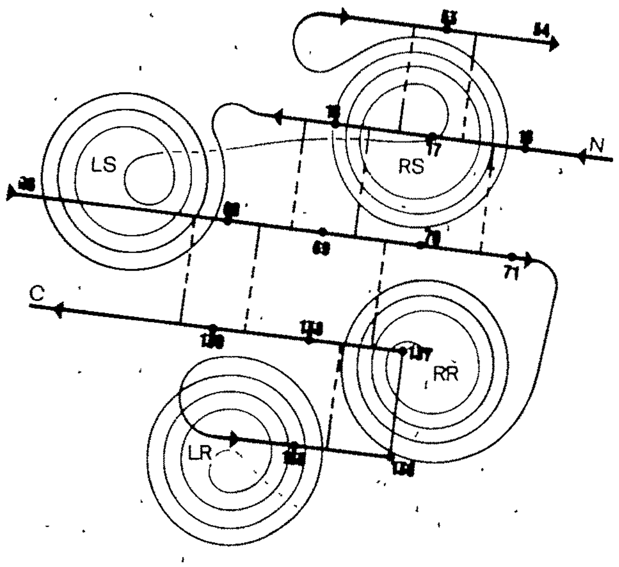

Fig. 3 Schematic view of the anti-parallel β sheet showing the connectivity of the strands and of the four principal α helices. The direction of view is along the long axis of the subunit towards the centre of the disk. The β sheet is a narrow, twisted strip which extends across the subunit bracing together the four α helices. At the bottom of the β sheet is a β bend which occurs immediately after the end of the LR helix. The bend is of type II where the second residue is commonly glycine and indeed Gly 137 is invariant in all known strains of TMV. The residues whose side chains are on the higher-radius side of the sheet are the two lysines (53 and 68), which form part of an extended salt bridge (Fig. 5), and three aromatic residues (Trp 17, Tyr 70 and Tyr 139) which form part of a cluster within the continuous hydrophobic girdle.

one ring onto one of the other. They are completely changed during the transition from disk to helix.

Contacts within a layer: By contrast, the four patches of alternating polar and hydrophobic contacts (Fig. 2) are maintained during the disk to helix rearrangement. There is no evidence of any relative motion within a subunit during this transition, and the coordinates of heavy-atom labels at four equivalent sites[26] in the disk and the virus show that the molecule moves as a rigid body[24]. Considerable flexibility is thus required in the side-chain contacts if the backbone conformation stays essentially rigid. During the transition, subunits in the A and B rings tilt[27] by 10° and 20°, respectively, about a tangential axis[5,9], so changing by 4° and 8° the hinge angle at the interface between neighbouring subunits, if these are envisaged as being related by a hinge extending radially along the interface. This change in hinge angle could mean an increased distance between the slewed helices in the upper part of the interface, a decreased distance between the radial helices in the lower part, or both of these. The first alternative is the least likely, as the transition results in a more compact structure[6] in which the subunits are closer to the central axis and the number of subunits per turn is decreased from 17 in the disk to 16⅓ in the virus. Figure 2 shows that in the disk the interface has more space between the radial than the slewed helices to allow the transition. Both the polar patches in the interface have residues which act as spacers: Arg 122 in the patch proximal to the axis and Tyr 72 in the distal patch. Rearrangement of the packing of these side chains allows the necessary movement in the polar patches. The non-directional character of the interactions in the hydrophobic patches could allow the apposed surfaces there to slide over each other during the transition.

Comparison with virus

In describing the structure of the RNA and its binding site, as deduced from a map of the virus itself using 4 Å data, Stubbs *et al.*[9] presented a model for the four main α helices which differs in several respects from that presented here. The largest differences are in the radial helices. Tyr 139 is located by a label in each model[24] and, whereas our model has a compact β bend separating this from Arg 134, the virus model has a greater separation. Comparison of our map with the 5 Å resolution map of the disk containing bound oligonucleotides[28], and computer model-building[19] indicate that, in the presence of bound nucleotide, the LR helix continues inwards to residue 109 or 110 before the chain turns upwards into the vertical column of density (V) seen in the virus map[9]. In the virus model this turn occurs at position 113, a difference of +3 or +4 residues between our model and the virus model. In our RR helix, Pro 78 occurs right at the bottom of the subunit marking a turn where the helix axis becomes more closely horizontal with increasing radius, whereas in the virus model the chain becomes less horizontal and then continues out in radius to residue 70. In our model we place Tyr 72 at the end of the radial density and residues 71 and 70 lie much higher than this radial helix (Fig. 4). None of the helices in the disk model have the idealised geometry which was built into the virus model, with the result that, although the two

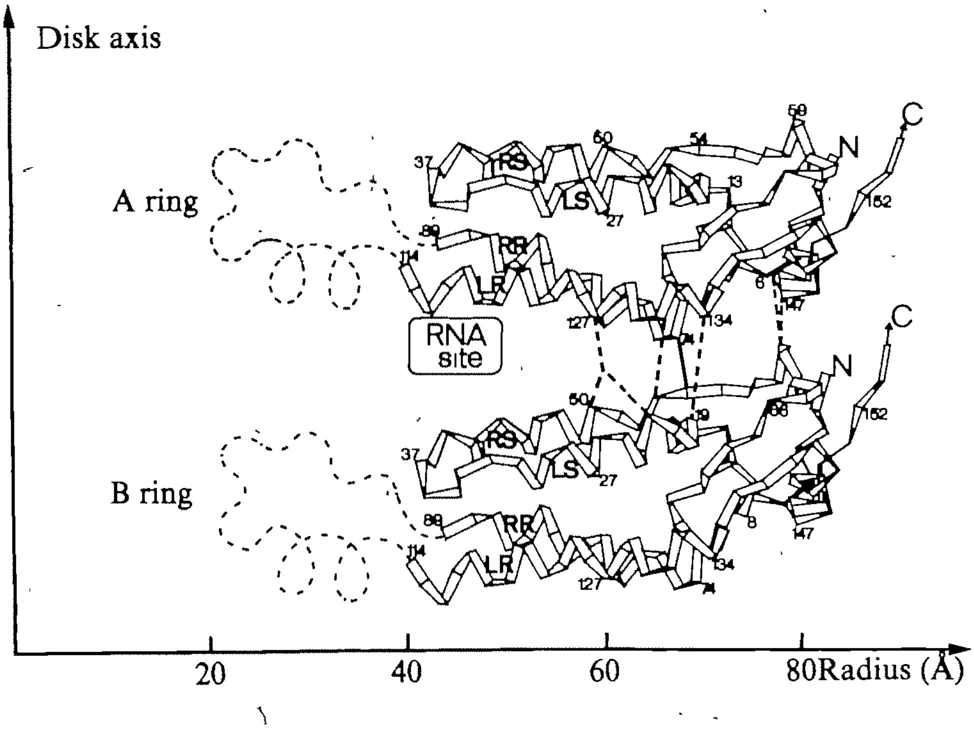

Fig. 4 Side view of a sector through the disk showing the relative disposition of subunits in the two rings and the axial contacts between them. There are three regions of contact indicated by a solid line for the hydrophobic contact of Pro 54 with Ala 74 and Val 75, by dashed lines for the hydrogen bonds between Thr 59 and serines 147 and 148, and further dashed lines for the extended salt-bridge system shown in greater detail in Fig. 5. The low-radius region of the chain, which has no ordered structure in the absence of RNA, is shown schematically with an indication of an additional 1–2 turns extending the LR helix (see text) before it turns upwards into the vertical column. The primary nucleotide-binding site is probably below the RR helix[28].

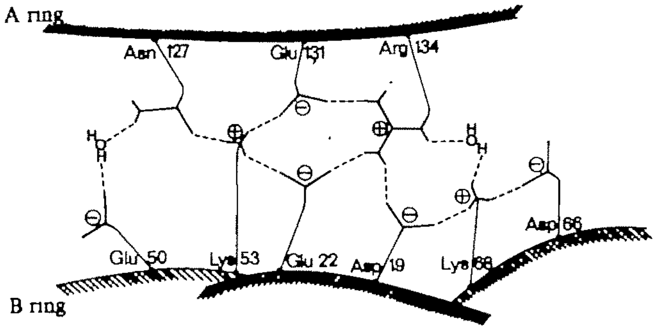

Fig. 5 The extended salt-bridge system between subunits in the two rings of the disk presented schematically in a side view. All three residues in the A ring emanate from the LR helix whereas those in the B ring arise from the 3_{10} extension of the RS helix and the top strand of the β sheet (50 and 53), the beginning of the LS helix (19 and 22) and lastly, the end of the upper loop and the third strand of the β sheet (66 and 68). The salt-bridge system, which utilises almost all possible hydrogen-bonding sites, is a complex three-dimensional network which is only presented here schematically. There are clear features in the electron-density map to represent both water molecules.

polypeptide chains may be out of phase by −2 residues beyond the distal end of the RR helices, both models can still have, for example, Asp 88 pointing out across the subunit interface. In the LS helix Cys 27 is located by a mercury site in both the disk[12] and the virus[29] but, whereas in our model Cys 27 points downwards towards the centre of the four-stranded supercoil, in the virus model it faces the RS helix[9], indicating a difference of +1 residue between the models.

The RR helix in the virus model continues for two or three turns beyond Asp 88 where, in the disk, it terminates at the start of the flexible loop. Extension of the RR helix beyond this point is not possible in our model because of interference from residues 38 and 41. Preliminary evidence from a low resolution study of oligonucleotides bound to the disk[28], while suggesting that the LR, LS and RR helices all move slightly upwards, still gives no clue as to how the flexible loop is folded. However, the different assignments of phase in the α helices mean, first, that our model has fewer residues to be fitted in between this point and the start of the LR helix and thus they need not be as tightly packed as the α helices of the virus model; and second, that the existence of a carboxyl cage[9], so-called in the virus model, must be treated with caution although, purely on the basis of the sequence, there must be a concentration of negative charges in this region of the molecule.

Discussion

The protein of TMV is the only protein from a large macromolecular assembly whose structure is now known at this level of detail. The subunit is a small protein folded into a single domain within which the folding of the amino and carboxyl halves of the polypeptide chain is quite similar. Between these two parts of the molecule there is an approximate twofold symmetry, which is geometrical as well as topological, indicative of a possible gene duplication (A. D. McLachlan, personal communication). The axis of this symmetry is along the centre of the four-stranded supercoil and approximately through the centre of the β sheet. Variation in the character of the protein along the direction of this axis reflects a segregation of function. Nearest to the centre of the disk is the flexible loop, awaiting interaction with RNA. Next comes the α-helical core and β sheet providing rigidity within the subunit while allowing flexibility across the interface. Last, at the distal end of the subunit is the hydrophobic girdle extending around the entire ring.

The discovery of the flexible loop in our 5 Å map[5] gave insight into the means whereby TMV protein can interact with, in effect, a random RNA sequence in the complete virus, and yet also recognise the special nucleation sequence of TMV RNA[7]. The binding site must combine the specificity required for the initial recognition of the special sequence with the ability to accommodate subsequently any sequence of RNA. Stereospecificity will be provided by the rigid parts of the protein in the vicinity of the RNA binding site: the proximal ends of the RR and LR helices and the hairpin bend, joining the proximal ends of the two slewed helices, which forms a rigid wall (with a concentration of invariant residues) facing into the cavity of the disk. Preliminary evidence suggests that nucleotides bind below the RR helix[28].

The mobility of the flexible loop in the disk is reminiscent of that found in the activation domain in trypsinogen[30]. Segments from four separate elements of this chain are flexible in the zymogen but become tightly interdigitated in the enzyme, after cleavage of the activation peptide and associated conformational changes, forming a rigid, correctly defined specificity pocket for binding the substrate. Creation of the binding site in TMV does not involve protein cleavage, as observed in trypsin, but it may be noted that when such cleavage does occur in the flexible region of disks of TMV it is essentially nonproductive, leading irreversibly to the stacked disk aggregate[31] of TMV protein which is not capable of initiating the assembly process.

The strong tendency of TMV protein to aggregate[1] can now be understood in terms of its surface properties. The hydrophobic nature of both the centre of the supercoiled bundle formed by the four α helices and the aromatic cluster in the centre of the subunit on the opposite side of the β sheet are not unusual, but the hydrophobic patches on the molecular surface would only be expected in a component of a larger assembly, not in a monomeric protein. These patches occur only within the lateral interface, which is essentially the same in the disk and the virus. This interface comprises hydrophobic and salt interactions which would both be favoured by higher temperatures, and indeed, TMV is a classical example of an entropically driven system[32]. The general character of the alternating hydrophobic and salt-bridge patches within this interface is conserved in all strains of the virus which have been sequenced, although the boundaries of the patches differ slightly between strains. A fuller discussion of this will be presented elsewhere.

The salt-bridge systems within the lateral interface remain on the transition from disk to virus, but the most extensive system, that between the layers of the disk, is completely disrupted by the transition, which changes the relative positions of subunits in the two layers both axially and azimuthally[5]. The interaction between subunits in successive turns of the virus places the first turn of the RR helix, which is the lowest part of the subunit in the A ring of the disk (Fig. 4), in the groove between the distal ends of the LS and RS helices.

The implications for virus assembly of this rearrangement were discussed in our previous paper[5]. The prediction that RNA interacts with TMV protein from the centre of the disk has been verified with the discovery of a hairpin loop structure[8] for the nucleation sequence within the RNA[7] and the observation that both tails of the RNA emerge from the same end of the growing rodlet[33,34]. Insertion of this loop into the central hole of the disk[6], and incorporation of RNA between the two layers, resolve the paradox posed by this two-layered structure. There is now no need to postulate separate mechanisms for the initiation and elongation stages of virus assembly. A travelling loop within the RNA which starts at the nucleation sequence for the initiation process and moves towards the 5′-end during elongation, uses the same forces of interaction for both processes. An understanding of this interaction in atomic detail must await the correlation of our model for the protein with the high-resolution fibre-diffraction pattern of the virus. This study is now in progress (in collaboration with Dr G. J. Stubbs).

We thank Drs P. J. G. Butler and J. Graham for help and for discussions, Dr R. Diamond for advice and the use of his graphics program, Mrs C. Harley for preparation of the crystals, Professor K. C. Holmes and the group in Heidelberg for a copy of their virus map and for showing us their atomic model, Trinity

College for the award of a Research Fellowship to G.B. and the Cambridge University Computing Service for making special arrangements for all the necessary computations. We also acknowledge the earlier contribution of the late Dr A. Jack (1948–78).

The polypeptide chain of a TBSV subunit folds into two domains, connected by a hinge, and a flexibly-linked N-terminal arm. Sixty of the 180 N-terminal arms interdigitate in groups of three, in an unexpected mode of protein association. The remaining 120 arms are not uniquely positioned with respect to the rest of the subunit. RNA is also not uniquely fixed to sites on the major domains.

SMALL, regular viruses self-assemble in solution[1,2]—implying that the protein subunits can associate correctly without further direction and that they can package nucleic acid. In most spherical viruses, correct assembly requires that a single type of subunit be capable of several, somewhat different bonding relations ('quasi-equivalence'). The structure of tomato bushy stunt virus (TBSV), as it appears at 5.5 Å resolution[3], shows that its subunit (MW ~ 40,000) achieves such flexibility by having two rigidly-folded domains with an interconnecting hinge. Two states of the hinge, differing by about 20°, are present in the $T=3$ (180-subunit) icosahedral structure. A large number of inter-subunit contacts are conserved in this way, maintaining specificity.

The low-resolution view of TBSV left a number of questions unanswered. How is the hinge flexibility controlled and a particle of correct size generated? With what precision are inter-subunit contacts conserved? How is RNA packed? To explore these questions, we have extended the resolution of the TBSV structure determination to 2.9 Å. We present here a first description of the results, which show several remarkable features. Near the N terminus of the polypeptide chain, 60 of the 180 chains are ordered, interdigitating in groups of three, whereas the remaining 120 extend in a less precise way towards the particle centre. Moreover, RNA does not seem to bind to the part of the subunit rigidly fixed in the surface lattice, and the structure suggests that the N-terminal arm, flexibly-linked to the rest of the subunit, has an RNA-binding function.

Structure determination

TBSV crystallises in the cubic space group I23, $a=383.2$ Å (refs 3–5). Diffraction to 2.85 Å was measured by oscillation photography[6], with a $\frac{1}{2}°$ range for each picture and with a total oscillation range of 25° about [110] required for a full data set. By translating a crystal between exposures, we could generally obtain two good photographs, and we therefore needed about 25 crystals for complete data. The films were scanned using a modified version of SCAN 12[7] to control an Optronics Photoscan interfaced to a PDP 11/20. As about 75% of the reflections were partially recorded, and as the crystal lifetime in any one location did not permit summing intensities of complementary spots on adjacent films in a series[6], a strategy for correcting to fully-recorded equivalents was adopted: details of the method will be published elsewhere (F.K.W. and C.E.S., in preparation). Corrected intensities were included in the final data set from only those reflections on any film that were at least half-recorded: by taking photographs with approximately abutting oscillation ranges, essentially all reflections were measured on one film or the other. The accuracy of measurements corrected in this way is comparable to the accuracy of fully-recorded reflections of the same observed strength.

Three data sets were collected: native and two derivatives (UO_2^{2+}, Hg^{2+}). The complete native data set contained 198,000 reflections: some statistics are given in Table 1*a*. Results of the heavy-atom refinement are shown in Table 1*b*. Phase determination by non-crystallographic symmetry averaging[8] proceeded in a manner similar to the phase refinement at 5.5 Å (ref. 3). A full account of the calculations, carried out at the CECAM Workshop on Virus Crystallography, will appear elsewhere (G.B., in preparation). A brief summary is included in Table 1*b*. The Fourier map used for averaging[8] was computed on a 0.6 Å grid from 182,000 terms between 16 and 2.9 Å; it had 37×10^6 points in an I222 asymmetric unit. The map computed after four cycles of phase refinement was used for the computation of

Table 1 Details of the structure determination of TBSV

a. Data collection:

Form	Reflections measured	R
	6 Å → 2.89 Å	
Native	182,000 (plus 17,000 to 6 Å from earlier work)	0.13
UO_2^{2+}	164,000	0.14
Hg^{2+}	130,000	0.15

$$R = \frac{\sum_h \sum_{j=1}^{N_h} |I_{hj} - \bar{I}_h|}{\sum_h N_j \bar{I}_h},$$ where the reflection, h, has been measured N_h times in data collection, and the average and differences are taken after appropriate scaling, and

$$\bar{I}_h = \sum_{j=1}^{N_h} W_{hj} I_{hj} \Big/ \sum_{j=1}^{N_h} W_{hj}$$ where $W_{hj} = 1/\sigma^2(I_{hj})$. The mean value of N_h for the native data set was 3

b. Phase determination:

Heavy-atom parameters (re-refined with phases after one cycle of noncrystallographic-symmetry phase refinement, using selected well-measured reflections; see ref. 3).

icosahedrally averaged maps of individual subunits, using a generalised skew planes procedure[8].

In considering the effects of icosahedral averaging, both in phase refinement and in examining the final maps, it is important to recall that the TBSV particles lie at positions of tetrahedral symmetry in the crystals. There is no chemical evidence for 'twelveness' in the particle—that is, no evidence for any special role for the tetrahedral subgroup of symmetry operations[9]. Therefore, the fivefold averaging imposed by the calculation is not 'smearing out' any structures (such as RNA or the possible unique subunit) that have not already been averaged out by the space group itself. Tetrahedral distortions of the particle, imposed by the lattice contacts, are of course always possible. But a difference map using $(|F_{obs}| - |F_{calc}|) \times \exp(i\alpha_{calc})$ coefficients, 'calc' referring to the last cycle of icosahedral averaging, showed no significant features; even near interparticle contacts. Such distortions must therefore be extremely small.

Maps of subunits in quasi-equivalent locations A, B and C (Fig. 1) were prepared, sectioned such that all three domains appear in the same orientation, using superposition parameters determined from the 5.5 Å map[3]. This presentation facilitates visual comparisons. Features in these averaged maps are extremely clean and well defined (Fig. 2): the polypeptide chain can be traced unambiguously, side chains are well-outlined, and main-chain carbonyls are visible for most residues. The structural results to be presented below are all derived from inspection and measurement of mini-maps (3.2 mm per Å) contoured from these averaged subunit densities. Model-building with an optical comparator and Kendrew parts is in progress.

Organisation of protein shell

The packing of protein subunits in TBSV is schematically illustrated in Fig. 1. The icosahedrally-ordered parts of the virus particle can be described as a compact polyhedral shell, about 30 Å thick, with 90 projections at strict and local twofold positions[3]. This structure is achieved by regular interactions of subunits that fold into two distinct globular domains, connected

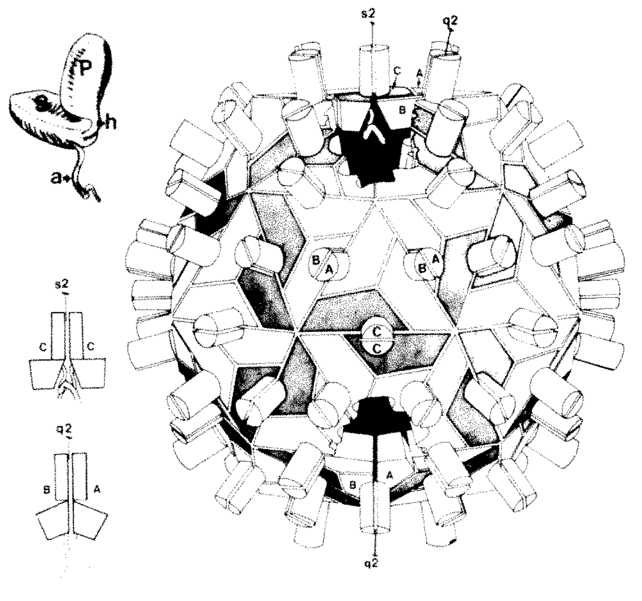

Fig. 1 Packing of protein subunits in TBSV. *a*, Schematic subunit, showing P and S domains, the inter-domain hinge (h) and the N-terminal arm (a). *b*, Arrangement of subunits in the virus particle. A, B and C denote the three packing environments of the subunit; outer surfaces of C subunit S domains are shaded. S domains of A subunits pack around fivefold axes; S domains of B and C alternate around threefolds. The quasi-threefold axis relating S domains of an ABC trimer is nearly parallel to the adjacent strict twofold (s2). Trimers therefore present a rather flat surface across the strict dyad and a distinctly sharper dihedral angle (about 40°) across the quasi dyad (q2). This difference in local curvature can be seen at the two places where the shell has been cut away to reveal S domain packing near strict (top) and quasi (bottom) dyads. *c*, The two states of the TBSV subunit found in this structure, viewed as dimers about strict (s2) and local (q2) twofold axes. Subunits in C positions have the inter-domain hinge 'up' and a cleft between twofold-related S domains into which fold parts of the N-terminal arms. Subunits in the quasi-twofold-related A and B positions have hinge 'down', S domains abutting, and a disordered arm.

by a hinge. We indicate these domains by the letters P (projection) and S (shell)—corresponding respectively to domains 1 and 2 in our previous paper[3]. The 2.9 Å electron density map shows that these domains include only about three-fourths of the sequence, and that the remainder of the chain forms an inward-projecting N-terminal arm. If we denote the three subunit packing modes by A, B and C (compare Fig. 1), then the overall organisation of the virus particle can be summarised as follows. The globular P and S domains fold in an essentially invariant manner. There are two positions of the inter-domain hinge—the A/B configuration (subunits related by a local twofold) and the C configuration (subunits related by a strict twofold), with a relative reorientation of about 20° in passing from one to the other. The A and B backbone conformations and hinge positions are indistinguishable at present, but some differences in side-chain conformations are evident. The conformation of the arm differs radically in position C from its conformation in A or B. Indeed, the map shows no density for the arm on subunits A and B, implying that it is not positionally fixed to the main body of the subunit. On C, however, the arm folds back along the edge of the S domain and interdigitates with two other such arms around the particle threefold axis, forming a remarkable structure described in more detail below. The folding of this part of the subunit depends on its contacts with several other subunits. These interactions seem to lace the particle together in a manner quite different from the cohesion provided by contacts between the independently folded globular domains.

Chain trace

The entire ordered part of the polypeptide chain has been traced without ambiguity (Fig. 3). At a few points, especially near heavy-atom sites, it was helpful to compare subunits in locations A, B and C (because we expect noise and artefact to be different in each), but in general each chain could be followed independently. Polarity was established initially by identification of carbonyls in the one α-helix, and confirmed by the orientation of carbonyls and C_β in β-sheets, by the handedness of β-sheet crossovers and so on.

The N terminus is in the particle interior; the C terminus, on the outside. The sequence of domains along the chain (N-to-C) is therefore: arm, S domain, P domain. The P domain comprises about 110 residues; the S domain, 168. The portion of the N-terminal arm on subunit C that is visible in the map contains

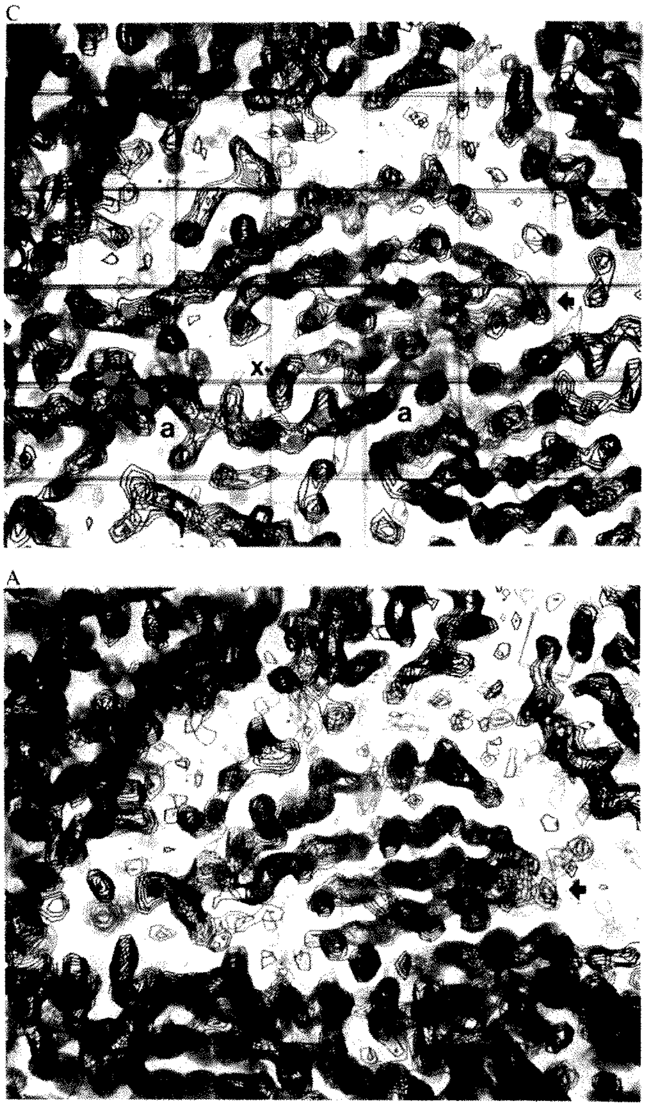

Fig. 2 Portions of the icosahedrally averaged final 2.9 Å electron density map of TBSV. The views are of the inward-facing surface of S domains of subunits A and C, as seen looking down a twofold axis (subunit C, oriented as shaded unit in Fig. 6), or quasi-twofold axis (subunit A). The sectioning of subunit A has been chosen to correspond as closely as possible to the sectioning of subunit C: the invariant fold of the S domain is evident from the comparison. Grid squares correspond to 10 Å. This part of the S domain is a four-stranded β sheet, with the arm (a) folded back alongside it in the case of C. The periphery of each photograph includes features from adjacent subunits, so that this part of the density appears different in each view. Note the large side chain (x), hydrogen-bonded to a backbone carbonyl of the arm of C and disordered on A. Bold arrows show the point where chain folds back into arm on C and extends more irregularly into the centre on A.

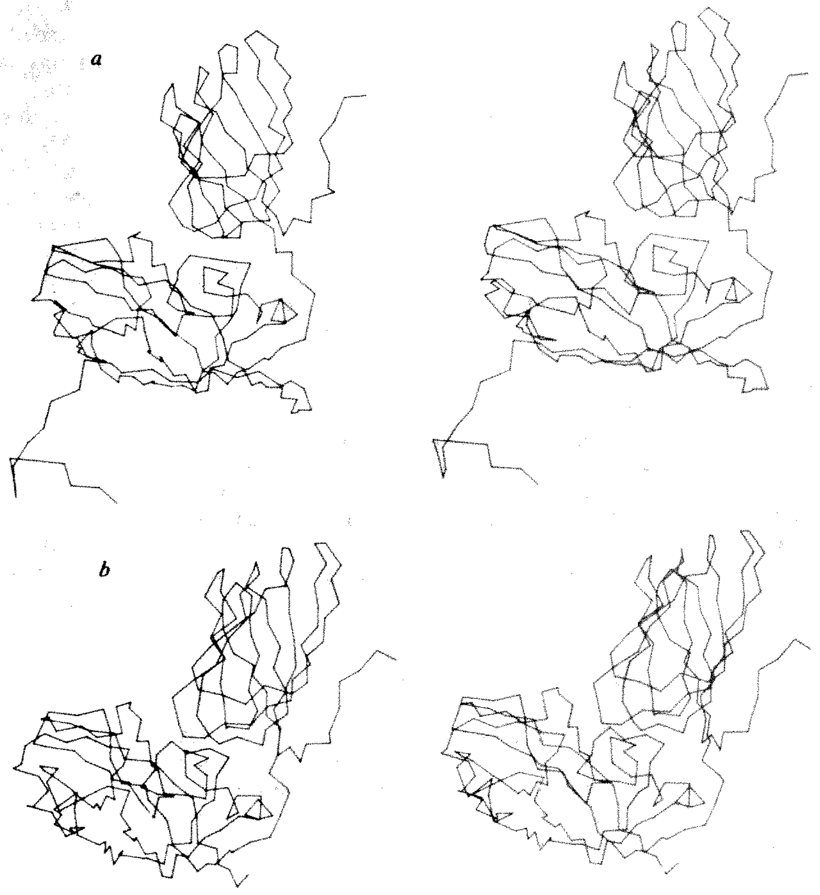

Fig. 3 Stereo views of the two states of the TBSV subunit: (*a*) C, with ordered arm and hinge 'up'; (*b*) A/B, with arm not fixed (and hence not shown) and hinge 'down'. The view of C is normal to the twofold axis, in the direction of the arrow in Fig. 6; the view of A is chosen such that S domains are as closely superposed as possible. The line segments making up these drawings join α-carbon positions, indicated by their intersection. The α-carbon coordinates were measured from mini-maps as described in the text.

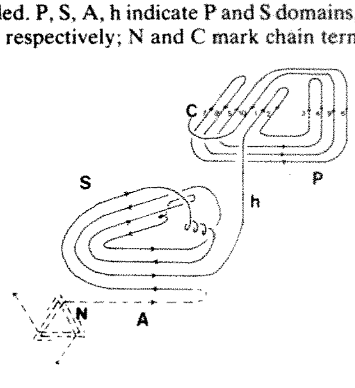
33 residues. The total of 311 identifiable residues corresponds to a molecular weight of ~34,000 (taking 110 as a mean residue weight). As the polypeptide chain molecular weight determined by gel electrophoresis and by gel filtration in guanidine hydrochloride[9,10] is 40,000 ± 2,000, there may be as many as 50 or 60 additional residues, not visible in the map even in subunit C. The connectivity of P and S domains and of the arm is clear. The C terminus also appears to be very clear: moreover, the position of specific sulphydryl cleavages as well as the remarkable protease resistance of the intact particle (A. Andreadis and S.C.H., unpublished) argues strongly against large 'dangling' loops at the outside. The most likely explanation for any difference between the number of visible residues and the expected total is therefore a further segment at the very N terminus. The complete N-terminal arm could then contain as many as 80–90 residues, all of them disordered in positions A and B, and the 33 closest to the S domain ordered in position C. Since the amino acid sequence is unknown, a more exact estimate cannot yet be made. We emphasise that the absence of density corresponding to N-terminal segments does not imply the absence of a regular fold for this part of the polypeptide chain; it requires merely that the terminus not be fixed spatially in the same way on all symmetrically related subunits.

The P domain is composed of two entirely antiparallel β sheets, one of six strands and the other of four (Fig. 4). The six-stranded sheet lies adjacent to a twofold axis and therefore packs against a similar sheet in the related subunit. The curvature of the four-stranded sheet is such that towards the particle centre (bottom of the domain in Fig. 3) it lies at some distance from the six-stranded sheet, with the strands curving gently around from one sheet into the other while preserving a β hydrogen-bond relationship. The two sheets are thus partly continuous along the chain direction (strands 4 to 5, 6 to 7, 8 to 9), although there appears to be no main-chain hydrogen bonding across the ends of the 'sandwich' (that is, between strands 2 and 3 or 6 and 7). About 20 residues at the C terminus form a strand that curls under the domain and up to the terminal residue, which lies at the subunit interface.

The S domain (Fig. 4) is also largely β sheet. It is shaped roughly like a triangular prism; a bent, four-stranded sheet forms the lower surface and one side of the most acute angle of the prism; a second four-stranded sheet forms the other side of the angle. The opposite face, and the upper surface, are formed by loops and by two short helical segments. The longer of these helices (about $2\frac{1}{2}$ turns) is tangentially directed and lies adjacent to a dyad; the other is a quite irregular helix of less than two full turns, radially directed, and packed against a sheet. The loops and helices appear to contain those residues most critically involved in variable inter-subunit or inter-domain contacts (compare 'contacts', below). In subunit C, the N-terminal arm folds back along an inner edge of the prism-shaped domain, forming a fifth element of one of the β sheets.

The inter-domain hinge consists of just two or three residues, with the backbone well ordered in each of the two observed configurations. There are probably small changes in several backbone torsion angles generating the hinge displacement.

Fig. 4 Schematic representation of the TBSV polypeptide chain, showing connectivity of domains and secondary structure within them. Lines with arrows indicate strands of β-pleated sheet (all antiparallel in this case). The N-terminal arm and β-annulus are shown by dashed lines, with segments of the two other chains in the annulus included. P, S, A, h indicate P and S domains, the arm and hinge respectively; N and C mark chain termini.

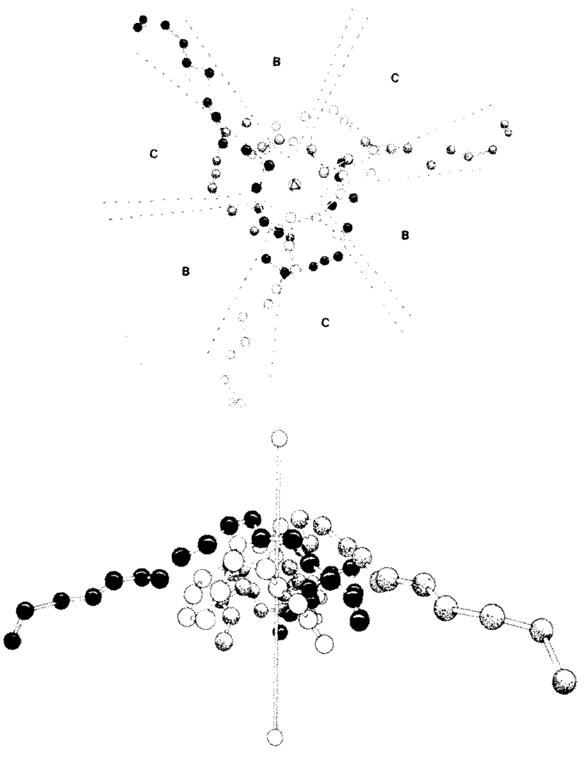


The chain trace described above exhausts all strong features of the map. Additional parts of the polypeptide chains, and all the nucleic acid, must be averaged over a number of orientations with respect to the principal domains. Density ascribed to RNA in interpreting the 5.5 Å map of TBSV ('*e*' in Fig. 2*b* of ref. 3) is now clearly seen to be the arm of subunit C.

N-terminal arm

The most remarkable aspect of the TBSV subunit is the configuration of its N-terminal portion. Following the chain in the C-to-N direction through the S domain in subunits A and B, we observe that the strong, distinct features in the map 'fray-out' and weaken at residue '35', and that any clear chain trace is impossible after about residue '33'. (The numbering scheme adopted here begins at the first visible residue on subunit C. Residue '1' may be up to 50 residues in from the actual N terminus: see preceding section.) By contrast, in subunit C, the chain executes a reverse turn and folds along the inner edge of the S domain next to the twofold axis. Its subsequent course is shown in Fig. 5. Extending towards the particle threefold axis, in the cleft between adjacent S domains, the chain makes a number of contacts with the neighbouring (B-type) subunit. On reaching the region of the threefold axis it winds anticlockwise around the axis (viewed from outside the particle), and inwards, forming a roughly 240° circuit from residues '18' to '1'. As there are, of course, two other symmetry-related chains, the 54 residues form an annular structure around the threefold axis. Their configuration is rather like the overlapping flaps of a cardboard carton: chain 1, over chain 2, over chain 3, over chain 1. This threefold ring seems to be stabilised by several sorts of interactions. Residues 3–5 of one chain, 11–13 of a second and 16–18 of a third form a little three-residue, three-strand β sheet: each chain enters such a sheet three times, once at each level, and the entire structure might well be called a 'β-annulus'. In addition to these main-chain interactions, there are important side-chain contacts. Residues 4 and 15, for example, have side chains that make contact around the threefold, partly defining the 'inside' of this small, globular cluster. Moreover, the entire cluster is suspended inward from the apices of the six neighbouring S domains (three C types, corresponding to the subunits to which the three participating arms 'belong', and three alternately intervening B types).

Fig. 5 Configuration of the β annulus, composed of three interdigitating arms. Balls show α-carbons; sticks are schematic indications of the peptide-chain connection. (*a*), View down threefold axis; (*b*), view normal to threefold axis.



It should be observed that, although the interdigitation of arms in the β annulus is at first sight complex, it presents no problem in principle for folding. No knots are implied, for example, and the structure can form by the interweaving of loops in a manner consistent with the presence of further chain distal to it. Nonetheless, this folding must occur during assembly, since the chain depends for its configuration on interaction with a number of neighbouring subunits. Indeed, the precise final organisation of the arm is clearly possible only when B-type subunits are present as well. In this respect, the arm of the TBSV subunit is similar to the N-terminal arm of LDH[11] and to crystalline glucagon[12], where acquisition of the observed conformation seems to depend on formation of the final assembly.

This map does not show the conformation of the arm of subunits A and B, nor that of any additional subunit C residues beyond the annular structure just described. The absence of strong density corresponding to these portions can have several possible interpretations. The segments in question could adopt more than one orientation from subunit to subunit. The map would then have a 'smeared-out' superposition of these alternative structures. The disorder could also be dynamic with all or part of these segments undergoing rather large-scale diffusional motion. Preliminary NMR measurements (C. Dobson and S.C.H., unpublished) lead us to prefer the former picture.

Subunit contacts

Individual domains are identically folded in all three quasi-equivalent subunit locations. We have not yet analysed intra-domain flexibility in detail, but its magnitude is relatively small (C_α superpositions of individual domains give r.m.s. differences of 1 Å or less, the expected measurement error). Variation is concentrated at the domain interfaces, both within and between subunits, and restricted to alternative positions of side chains rather than of the backbone. We can obtain a first description of the capacity of a TBSV subunit for variable packing by examining the degree of conservation or nonconservation of side chain conformation and interaction at the domain interfaces.

Each local symmetry element gives a class of subunit contact (Fig. 6). These contacts may be further subdivided according to the domains involved. The analysis is summarised in Fig. 6. In general, it seems that contacts are either fully conserved (identical side chain packing at quasi-equivalent positions) or distinctly altered. The fivefold/sixfold contacts are a good illustration. These contacts are 'quasi-equivalent' in the sense that they involve the same parts of the subunit. 'Sixfold' is something of a misnomer, however, except in the sense of coordination. As shown already at 5.5 Å, pairwise contacts of the six S domains packed about a strict threefold axis alternate in character[3]. Proceeding anticlockwise (viewing from outside the particle), C → B contacts are essentially identical to contacts about a fivefold axis, while B → C contacts involve quite different interactions, due to intervention of the C subunit arm. At these, as at other non-conserved interfaces (S domain twofold contacts; P domain/S domain contacts), side chains that make important interactions in one state often appear rather disordered in the other.

The conserved local-threefold interfaces have one particularly interesting feature—an ion, perhaps calcium, coordinated by side chains from both subunits. This site is probably linked to an EDTA-induced swelling observed at *p*H 7.5 (S.C.H. and A.J.O., unpublished).

RNA

There is no strong density in this map that can be ascribed to RNA; the entire inner cavity of the virus particle ($r < 112$ Å) is devoid of dense or interpretable detail. This cavity must, however, contain both the nucleic acid molecule and the protein

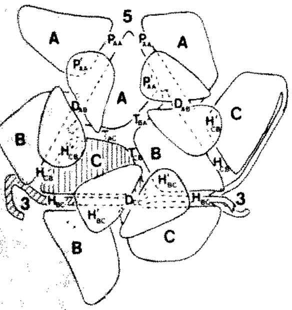


Fig. 6 Schematic diagram showing subunit packing and contacts. The diagram is effectively a more detailed view of the lettered subunits seen nearly face-on in Fig. 1. The domains are indicated in rough outline: barrel-shaped P domains protrude outwards, making only twofold contacts, while the more extensive S domains make contacts across all adjacent symmetry axes. The arms of subunits C fold back as indicated; the arms of A and B are not fixed. The shading of one subunit C indicates which P domain (stippled) is associated with the labelled S domain (hatched). Contacts between subunits are lettered to provide a key for the Table. The cation sites (see text) are near the letters 'T'.

Conservation and shift of inter-subunit contacts

Contact	Code in Figure	Packing
P domain/P domain		
Twofold	D_{CC}	Conserved (apposed β-sheets)
Quasi-twofold	D_{AB}	
S domain/S domain		
Twofold	D_{CC}	Non-conserved (Helices roll over each other; sheet edge contacts displaced by arms)
Quasi-twofold	D_{AB}	
Quasi-threefold	T_{AC}, T_{CB}, T_{BA}	Conserved (Ca^{2+} site)
Fivefold	P_{AA}	Conserved
Quasi-sixfold (fivefold-like)	H_{CB}	
Quasi-sixfold (across cleft)	H_{BC}	Non-conserved (Displaced by arm)
P domain/S domain		
Fivefold	P'_{AA}	Conserved
Quasi-sixfold (fivefold-like)	H'_{CB}	
Quasi-sixfold (across cleft)	H'_{BC}	Non-conserved (Different residue of P domain contacts top of short radial helix)

arms. The volume available to RNA, allowing for the arms, is about 5×10^6 Å^3. This corresponds to about 1.5 g H_2O per g RNA—equivalent to the hydration of DNA in phage heads[13] or to the solvent content of orthorhombic yeast-phenylalanine-tRNA crystals (about 1.3 g per g, ref. 14). TBSV RNA is therefore very tightly packed.

Small angle X ray[15] and neutron scattering from TBSV in solution (B. Jacrot, personal communication) indicate that RNA is present at radii immediately internal to the S domains seen in the present map. We have considered whether dissociation of RNA from fixed binding sites on this domain might have been produced by the relatively high ionic strength (~1.2 M) required for crystallisation. We have succeeded in obtaining high-resolution X-ray photographs from TBSV crystals in 0.1 M $(NH_4)_2SO_4$, 20% polyethylene glycol (ionic strength ~0.3 M): no significant intensity changes are observed at any resolution. Moreover, we note that the inward-facing part of an S domain presents a relatively smooth surface to the interior, unlike the clefts between distinct lobes that characterise the active sites of catenases such as lysozyme and ribonuclease[16]. We conclude that equivalent subunits do not necessarily 'see' RNA in the same position or orientation, thus accounting for the absence of strong high-resolution features.

How, then, does RNA interact with the TBSV subunit? The arguments just outlined imply that the arms of subunits A and B, and the presumed N-terminal part of the arm of C, are interspersed in some way with RNA. Detailed interpretation of neutron scattering suggests considerable penetration of protein towards the particle interior (B. Jacrot, personal communication). We have at present no direct evidence for specific interaction, but the arms are obvious candidates for protein-RNA binding. An RNA-binding region adopting various positions with respect to the body of the subunit might find good contacts, whatever the detailed three-dimensional arrangement of RNA; it would thereby gain the advantage of relative insensitivity to nucleotide sequence.

Implications for assembly

The 2.9 Å map has revealed two quite unexpected aspects of the TBSV structure. A portion of the polypeptide chain near the N terminus interdigitates with others in an unusual fashion in one state of the subunit (C) and appears disordered in the other, quasi-equivalent positions (A/B). Moreover, RNA appears not to bind to the rigidly-anchored S domain; it may instead interact with the flexibly-linked arms. Some interaction of RNA and protein is required for self-assembly.

We have as yet no information about the pathway of TBSV assembly, but we would like to draw attention to one striking feature of the particle design. The threefold-linked arms, together with the D_{cc} contacts, interlace subunits in such a way that all sixty C type subunits are interconnected, without mediation of A or B (see Figs 1, 6). That is, removal of all A and B subunits would leave a still intact, though fenestrated and cage-like, shell. Moreover, all subunits in this shell would be exactly equivalent in conformation and bonding. Twofold (P domain) and threefold (β annulus) contacts in such a structure would determine completely a 60-subunit framework, though perhaps a rather floppy one, connected like the edges of a pentagonal dodecahedron. This hypothetical structure illustrates that no 'switch' is needed to control hinge configuration or size determination. With C subunit arms linked to form a β annulus, the intervening gaps can be occupied only by subunits that adopt an A/B conformation, having hinges 'down' and unlinked N-terminal arms. That is, if linkage of the arms is important in building up a particle, non-equivalent aspects of subunit packing are automatically built into the bonding scheme. Moreover, as A/B subunits are introduced into a network of C's, the structure acquires the rigidity and curvature of a complete T = 3 virus shell.

We are grateful to Dr Carl Moser (and to U., J., and J.W.) for organisation of a CECAM Workshop, at which phase refinement calculations were carried out; to J. Crawford, C. Steele and I. Robinson, for advice and assistance; to Professor W. N. Lipscomb, for use of an Optronics Photoscan; to the Chemistry Department of Harvard University, the Columbia University Computing Center, and the Cambridge University Computing Centre, for computer facilities. The electron density map was plotted using graphics facilities at the MRC Laboratory of Molecular Biology, Cambridge, and we thank C Villa for assistance with the photography. Incidence of ionised gas in E/SO radio galaxies

SEVERAL nearby E and SO galaxies are known to contain weak ($L_{\rm rad} \sim 10^{39}$ erg s^{-1}) radio sources[1-3]. Heeschen[4] found that these sources fall into two distinct classes: 'extended' sources with steep radio spectra and sizes comparable to their parent galaxies, and 'compact' sources with flat spectra, which are centred on the optical nucleus and have sizes smaller than a few arc s. Although ionised gas is generally inconspicuous in E/SO galaxies, spectroscopy of ~24 E/SO radio sources[3,5,6] suggests a high incidence of optical emission lines in galaxies with compact radio structure. The two best-known examples, NGC1052 and NGC4278, have, in addition to unusually strong emission lines, abnormal amounts of neutral hydrogen[7-9], and this has led to the speculation[10] that radio outbursts in early type galaxies are fuelled by accretion of neutral gas, possibly from intergalactic clouds. As part of an optical study of E/SO sources with flux densities higher than 20 mJy from the deep Arecibo radio survey of Dressel and Condon[11], we have recently obtained spectrophotometry of 57 objects which makes the radio structure–optical line emission correlation more definitive. The 2,380 MHz Arecibo survey of bright Uppsala General Catalogue galaxies included 2,095 objects with $0° \leq \delta \leq +37°$. 24% of the E, and 12% of the SO galaxies were detected at the 5σ level ($S_{2380} > 15$ mJy). Interferometer observations[12] of the brighter sources allowed separation into the compact (CRS) or extended (ERS) categories; continuing work with higher resolution indicates that several ERS objects have a well-defined double structure (J. J. Condon, personal communication). The optical observations were made with the image dissector scanner on the Kitt Peak National Observatory 2.1 m telescope in December 1977. The scanner was operated with an 8.4-arc s diameter entrance aperture, which yielded an effective resolution of ~11Å. Scans covered $\lambda\lambda$ 3400–5200. We confine our attention here to [O II] λ 3727, which is expected to be ~10 times stronger against the galaxy background in objects with spectra like NGC1052 (ref. 8) than is Hβ.

The limiting detectibility for our discussion is $W(3727) \sim 0.6$ Å equivalent width. A more refined analysis which includes comparison to line-free absolute energy distributions should yield a limit of ~0.2 Å. For comparison, the limit for [O II] observations by Humason, Mayall and Sandage[13] is ~10 Å. Our observations included all Arecibo E/SO detections with $0\,{\rm h} < \alpha < 11.7\,{\rm h}$ or $20\,{\rm h} < \alpha < 24\,{\rm h}$ and with $S_{2380} > 30$ mJy, as well as five fainter detections. Additional CRS objects were selected from lists of sources outside the Arecibo declination limits. Finally, a selection of non-radio source (NRS) E/SO galaxies, with $S_{2380} \leq 3$ mJy was included from the Arecibo survey as a control group. Objects with morphological classifications later than SO in the reference catalogue[14] are excluded.

Results are shown in Fig. 1, which plots $W(3727)$ against a radio-optical flux ratio defined as $R = 10^{-5}\, S_{2380}/10^{-0.4m}$, where m is a corrected apparent magnitude described in ref. 12. Apart from the three Seyfert galaxies, two of which (UGC3374 and 5025) are newly identified Seyfert 1 objects, rich emission line spectra were not encountered. (The Seyferts are probably spirals, not E/SO galaxies[15].) Figure 1 also shows a histogram of line strengths in NRS objects. Only 4, or 20%, have detectable λ 3727. For the ERS objects, only 4 out of 16 were detected, and one of these has a compact core component contributing 20% of the total flux. The two strongest ERS [O II] detections (and two of the four NRS cases) exhibit evidence of young stellar populations, and their line emission may be unrelated to their radio properties. In contrast, all 12 Arecibo CRS objects and four out of six non-Arecibo CRS objects were detected. Most of these have $W(3727) > 10$ Å, whereas only one ERS/NRS detection is this strong.

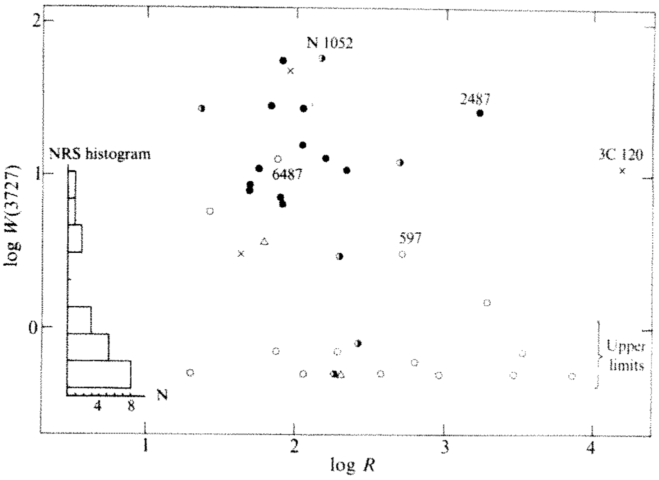

Fig. 1 A plot of the [O II] equivalent width against a radio–optical flux ratio described in the text. Strengths < 1 Å are upper limits. At the left is a histogram of [O II] strengths in non-radio source objects, for all of which $R < 6$. CRS objects have > 50% of their radio flux originating in a region < 6 arc s in diameter. The notation ERS + CRS indicates objects with distinct core components which contribute < 50% of the flux. Labels without prefixes are UGC numbers. ○, ERS; ●, CRS; ◑, CRS, non-Arecibo; △, ERS + CRS; ×, Seyfert.

We thus conclude that among E/SO galaxies, CRS objects have a high probability of strong [O II] line emission whereas ERS objects, despite R values which are typically an order of magnitude higher, are no more likely to exhibit [O II] than galaxies without detectable radio emission. Because most CRS objects are SO galaxies while most ERS objects are E galaxies[12], it is important that this relationship holds for E or SO systems considered separately, although the samples in each category are small. On the basis of these results, one expects that a large fraction of E/SO galaxies with [O II] detected by Humason, Mayall and Sandage[13] will turn out to have compact radio cores. There is no obvious correlation in Fig. 1 between [O II] strengths and the luminosity of the compact source, suggesting that photoionisation by non-thermal radiation may not be responsible for heating the gas.

Because compact radio sources require replenishment of relativistic electrons on a much shorter time scale than extended sources, it is reasonable to expect a correlation like that observed here if infall of thermal gas on to a condensed nuclear object is responsible for the production of relativistic plasma. It now seems that such gas in most cases must originate inside the

0028–0836/78/0276—0374$01.00

parent galaxy, as the lack of intergalactic H I clouds[16,17] together with the fact[12] that CRS objects are not preferentially found in galaxy groups or clusters argues that accretion of external gas is rare and probably unnecessary for CRS production. Rather special conditions are required for accretion of hot intracluster gas[18]. Gas lost during normal stellar evolution can readily meet the power requirements of these sources if it is acquired by an accretion disk surrounding a massive black hole.

The high incidence of line emission in CRS objects does not, however, prove that gas infall fuels radio outbursts. The compact source may merely provide a heating mechanism for small amounts of neutral gas (say $\sim 10^6 M_\odot$, which is impossible to detect with current 21-cm sensitivities[7]) which are incidentally present in E/SO galaxies. In ERS objects, emission might be suppressed through stripping of the thermal gas by an external medium (as most ERS sources apparently reside in clusters or groups), through stripping during the ejection of extended components, or through the strict channelling of relativistic energy in beams which may supply the double sources[19]. Further work on the statistics of the ionised component, its kinematics and its spatial distribution would be of great interest.

Search for X-ray emission from AO0235+164

THE BL Lacertae object, AO0235+164, is one of the best documented cases of the inverse-Compton scattering problem, that is, the brightness temperature of the emitting region, as implied by rapid variability and cosmological redshift distance, is well in excess of 10^{12} K. If the variable emission is produced by incoherent synchrotron radiation, then at these brightness temperatures the electrons would preferentially Compton scatter from their own synchrotron-emitted photons producing an excessive X-ray flux and subsequent cooling. In late-1975 AO0235+164 underwent an enormous outburst at radio[1,2], infrared and optical[3] wavelengths, for which Ledden *et al.*[2] deduced a brightness temperature $\geq 10^{15}$ K at 8 GHz. This source is also an active variable at low frequencies[4,5] (≤ 1 GHz). We describe here our search for X-ray emission from AO0235+164.

Explanations of this enormous outburst and related phenomena have invariably involved abandonment of one or more of the basic assumptions[6–9]: incoherent synchrotron emission by electrons, nonrelativistic expansion, cosmological redshift distance, or random geometry. Some of the explanations proffered, such as those involving coherent emission[7], synchrotron proton radiation[6] or special geometry[8], predict that the inferred brightness temperature is the observable brightness temperature of the varying region, although no such high brightness components ($\sim 10^{15-16}$ K) have been detected in recent searches for their expected interstellar scintillations[10–12]. In the case of AO0235+164, unfortunately, such a high brightness component may be unobservable due to possible angular broadening caused by the $z = 0.524$ absorption redshift system.

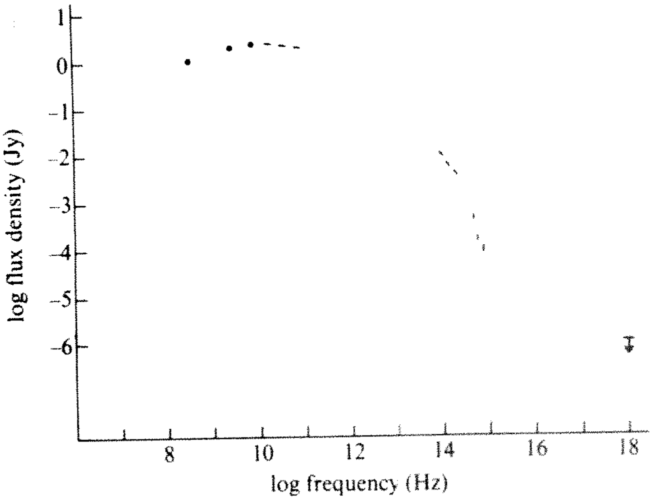

Fig. 1 Spectrum of AO0235+164. Vertical extent of bar (optical data) represents range of galactic extinction corrections used in ref. 21 (December 1977). This data is uncorrected for extinction in the $z = 0.524$ absorption redshift system. Dashed lines are based on observations at other epochs (see text). ●, Data from ref. 5 (March 1978); ⊥, this work.

It is clearly important to determine or set restrictive limits to the level of X-ray emission in compact objects. We chose AO0235+164 for our investigation on the basis of its previously discussed properties, and its high density of radiant energy inferred from VLBI observations[4]. Before its late-1975 outburst a limit of ~ 20 μJy at 10^{18} Hz could be set[13]. Since the outburst, the radio flux density has remained well above the 1974 minimum (0.6 Jy) indicating continuing injection of particles (Hugh Aller, personal communication).

The observations were carried out with the rotating modulation collimator (RMC) experiment aboard the SAS 3 X-ray observatory[14,15]. Both RMC systems having FWHM of 2.3 arc min and 4.5 arc min were used in the 2–6 and 6–11 keV bands. AO0235+164 was observed from 17.4 to 22.4 November 1977, a time when the Sun angle for this source was $\sim 180°$, thus maximising the usable data per orbit. The total exposure was 2.6×10^6 cm^2 s. Correlation distributions for different data channels and each orbit were constructed[16] and co-added to produce distributions for the entire observation in both energy bands. No emission was detected in either energy band at or near the best available radio position[17]. The limit to our sensitivity is imposed by counting statistics due to the background. The 3σ upper limit to the counting rate over the entire 2–11 keV band is 0.54 s^{-1}. This corresponds to a total flux limit of 2×10^{-11} ergs s^{-1} cm^{-2} over this range. The flux density at 10^{18} Hz is therefore ≤ 1.0 μJy. For the relatively flat X-ray spectrum expected for this source, these flux limits are insensitive to the assumed spectral index.

This upper limit allows us to place restrictions on first order Compton scattering, and therefore the brightness temperature and angular size, θ, of the compact radio source[18–20]. The overall spectrum around the time of our observation is shown in Fig. 1. The dashed lines indicate extensions of the radio and optical spectra into the infrared, strongly suggested by observations of this source at other epochs[21]. The optical flux may be depressed by several magnitudes of extinction in the $z = 0.524$ absorption redshift system[4], and thus the B-magnitude does not provide the

0028–0836/78/0276—0375$01.00

best limit to first order Compton scattering. At the time of our observation the optical flux was near a minimum[21].

The radio spectrum does not exhibit a well-defined synchrotron self-absorption turnover. The very broad peak at 10 GHz could be best explained by an inhomogeneous synchrotron source[22], each component of which has a fairly flat spectral index. Ledden *et al.*[2] found $\alpha \approx 0.15$ in fitting the outburst spectrum to several self-absorbed components. Conservatively, we shall use $0.2 \leqslant \alpha \leqslant 0.5$, as large values of α produce the smallest lower limits on θ. Apparently, the radio flux decreases beyond 10 GHz. We shall, therefore, consider that the relevant component becomes optically thick at 10 GHz, as this also gives the smallest lower limit on θ. We also assume that the radio spectrum continues to at least 10^{12} Hz before cutting off, as suggested by an apparent continuity between the radio and infrared spectra[21]. This is necessary if Compton scattering is to produce X-rays at $\gamma^2 10^{12}\ \text{Hz} \approx 10^{19}$ Hz.

The maximum brightness temperature, T_n, occurring at frequency ν_n, is given by[20,23]

$$\frac{F^c_{\nu_c}}{F^s_{\nu_s}}\left(\frac{\nu_c}{\nu_s}\right)^{\alpha} \simeq \frac{16\pi}{3}\,\frac{j^{sc}_{\alpha 0}}{k_{\alpha 0}}\ln\Lambda\,\frac{r_e\nu_n}{c}\left(\frac{kT_n}{i_{\alpha 0}mc^2}\right)^{3+2\alpha}(1+z)^{4+2\alpha}$$

where $F^s_{\nu_s}$ is the synchrotron flux density at optically thin frequency ν_s, $F^c_{\nu_c}$ is the Compton-scattered flux density at frequency ν_c, $j^{sc}_{\alpha 0}$ and $k_{\alpha 0}$ are dimensionless functions of α (given in ref. 18), ln Λ is a function of the cutoffs in the electron spectrum[18], r_e is the classical electron radius, and m is the electron mass. We then find $T_n \leqslant 2.4 \times 10^{11}$ K, and correspondingly $\theta \geqslant 0.38$ m arc s, independent of distance (except through redshift corrections). This limit is derived for $\alpha = 0.5$. If, however, $\alpha = 0.2$, then we obtain $T_n \leqslant 1.5 \times 10^{11}$ K and $\theta \geqslant 0.50$ m arc s.

These values are to be compared with the 10.8 Ghz VLBI angular size measured in January 1978 with a transcontinental baseline (to be reported fully elsewhere by J. Broderick, *et al.*). It was found that $\geqslant$80% of the source is contained within a component of angular size $\leqslant$0.30 m arc s. In view of the various uncertainties involved in the application of the synchro-Compton model, and the interpretation of the VLBI visibility data, we do not consider this to be a major discrepancy. Of interest, however, is the possibility that it may indicate the presence of relativistic expansion in the source. Given the distance implied by the largest absorption redshift present (0.851) we can calculate the physical dimension of the source, l, and therefore the energy contained in relativistic particles, U_e, and magnetic field, U_B (refs 19, 23). Taking $\theta \simeq 0.30$ m arc s and $H_0 = 55$ km s^{-1} Mpc^{-1}, we find that $l \simeq 2.8$ pc, $U_e \simeq 3 \times 10^{54}$ erg, and $U_B \simeq 3 \times 10^{53}$ erg, for $\alpha \simeq 0.2$. If $\alpha \simeq 0.5$ then $U_e \simeq 1.4 \times 10^{55}$ erg and $U_B \simeq 5 \times 10^{52}$ erg. In either case the ratio of particle to magnetic energy, E_{em}, is large ($\geqslant$10), and the dynamics must be particle dominated. This would indicate relativistic expansion if the mean energy per particle is comparable to or greater than the rest energy of those particles that neutralise the electron plasma.

If the source is relatively local[6], then the physical size is reduced accordingly, the energy requirements are reduced substantially, but the dynamics remain particle dominated because $E_{em} \propto l^{-1}(1+z)^9$. The minimum of E_{em} occurs for $l \simeq 700$ Mpc, in which case $E_{em} \gtrsim 1.5$. Placing the source at a distance at which the brightness temperature inferred from the late-1975 outburst is 10^{12} K (~200 Mpc) gives $E_{em} \gtrsim 3$.

Wolfe *et al.*[4] found that the observed brightness temperature is $\gtrsim 10^{12}$ K at ~1 GHz, in excess of the inverse-Compton limit $\simeq 10^{12}\ \text{K}/(1+z) \simeq 5 \times 10^{11}$ K. In a static synchro-Compton model this would produce an excessive infrared or optical flux, further requiring that relativistic expansion be invoked.

The magnetic field, **B**, can be calculated independently of distance[19]. If $\theta \simeq 0.30$ m arc s, then $\mathbf{B} \simeq 0.4$–0.12 G depending on assumed spectral index. As long as $\mathbf{B} \leqslant 0.15$ G, then the electrons radiating at 10^{12} Hz are able to cross the source before losing their energy through synchrotron losses.

It would be interesting to determine better the magnitude of the discrepancy reported here. This can be accomplished by observations with the HEAO B X-ray observatory and VLBI observations over a longer baseline. Thus it will be possible to determine the extent to which relativistic expansion or other effects must be included in the synchrotron radiation models.

We thank Dr W. Mayer and F. Pineda for assistance with the observations, and Drs J. J. Broderick and S. L. O'Dell for useful discussions. B.D. was a guest observer for this observation. This work is supported by NASA grant NSG 5221, and partially supported by NASA contract NAS5-11450 and MIT subcontract SC 22152.

IUE observations of the eclipsing binary Epsilon Aurigae

THE eclipsing binary Epsilon Aur is a most peculiar binary system and it has not been explained satisfactorily. We report here our observations of this system using the International Ultraviolet Explorer (IUE) collected at the Villafranca Satellite Tracking Station of the European Space Agency (SA).

Epsilon Aur is a single-spectrum binary whose visible component is a supergiant F0 Ia; it is eclipsed once every 27.1 yr by its invisible companion. The eclipse is total and lasts 714 d. The amplitude is 0.8 mag and is independent of wavelength. The eclipse is peculiar for these reasons: (1) during totality the spectrum of the primary F0 Ia star is always seen; (2) from the amplitude of the minimum the two stars might be expected to have about the same magnitude, a point which cannot be reconciled with the fact that only one spectrum is visible at maximum light, even when doubling of lines is expected. These inconsistencies can be removed by assuming that the invisible companion is surrounded by a disk or ring which is the eclipsing body. The fact that the minimum amplitude is independent of the wavelength was explained by assuming that the eclipsing body is a disk or ring of dust particles[1–3] or of ionised atoms

0028–0836/78/0276—0376$01.00

which explain the opacity of the disk or ring as produced by electron scattering only[4].

This second hypothesis was suggested by the characteristics of the spectrum of the eclipsing body, which can be observed during the partial phases of the eclipse[4]. It is not identical to the F0 Ia spectrum, as would be expected if it were due to stellar light simply scattered by dust particles, but the lines originated from non-metastable levels are much fainter than those in the stellar spectrum which indicates that they are formed in a rarefied gas. However, the non-metastable levels of Mg I, Ca I and Fe I are more populated than is expected from the diluted radiation of the primary star at the surface of the eclipsing body. Hence, if the primary were responsible for the excitation of the eclipsing body (as suggested by Kuiper, Struve and Strömgren[5]), it must be richer than expected in UV radiation.

To explain the observations, it has been suggested[4] that the UV radiation does not come from the F0 primary, but from the invisible companion, which is assumed to be a hot star surrounded by a ring of ionised gas. Other suggestions[3,6] were that the secondary could be a black hole; the source of high-temperature radiation required for explaining the spectroscopic features of the eclipsing ring could be provided by the accretion mechanism, heating the gas at ~10^6 K (ref. 3).

To check these various hypotheses and discover the nature of the companion, we have observed the UV spectrum of Epsilon Aur with IUE, using the low-resolution mode (FWHM 5.5 to 7 Å) for the far UV (λλ 1150–1900 Å), and the high resolution mode (FWHM ~ 0.15 Å) for the near UV (λλ 1900–3200 Å). The observations were made on 19 April 1978 at phase 0.81 P. The exposure times were 30 min in the low-resolution, and 60 min in the high-resolution mode. The low-resolution spectrum indicates the presence of a hot object whose continuum is interrupted by several absorption lines and by a strong emission identified with λ 1302 O I (Fig. 1). The high-resolution spectrum is that expected for an F-type supergiant.

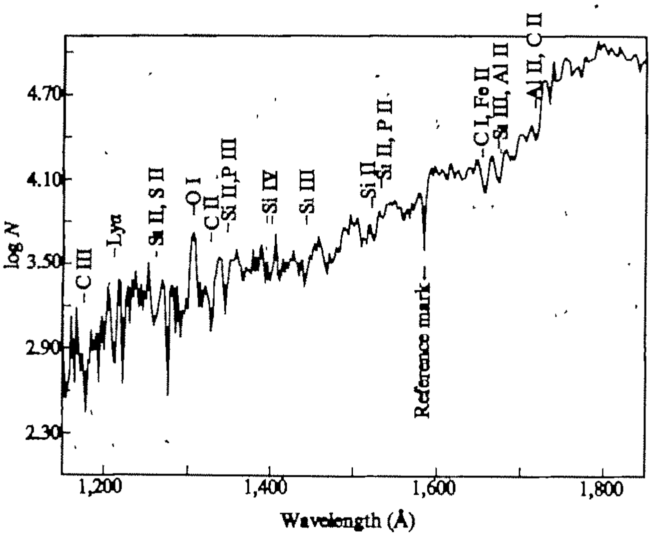

Fig. 1 The low-resolution short-wave spectrum of Epsilon Aur.

The output of the IUE software N, or net flux (corrected for the background), is transformed into absolute flux $\mathcal{F}(\lambda)$ (in erg cm^{-2} s^{-1} t^{-1}) by the relationship $\mathcal{F}(\lambda) = N(\lambda)S(\lambda)^{-1} t^{-1}$ where $S(\lambda)$ is the sensitivity of the IUE camera determined by Bohlin (personal communication) and t the exposure time (s). The values of the sensitivity should be considered as preliminary. Comparison of the fluxes from standard stars observed with OAO 2 and with experiment S2/68 on TD 1 with those observed with IUE (low-resolution mode, large slit 10″×20″) gives an uncertainty of 20% or better (as stated by the resident astronomers). However, our observations were made using the small aperture (3″ hole); in this case the light loss for both spectrographs is estimated to be ~50±20%. The transmission of the small aperture is grey to ±2%. Hence our measured flux is lower than the true flux but the energy distribution is not affected.

The continuum has been traced as a smooth line passing through the highest points of the whole spectrum N versus λ. The faint image at wavelengths shorter than the sensitivity limit at λ 1150 indicates the presence of light scattered from longer wavelengths. The amount of this scattered light is evaluated by measuring the net flux N remaining at the centre of Lyα ($N = 500$). By subtracting this value from the net flux we compute the absolute observed flux corrected for scattered light. Then the flux is corrected for interstellar extinction using the relationship of Nandy *et al.*[7] for $E(B-V) = 0.30$. This value of $E(B-V)$ is obtained by plotting the equivalent width of the interstellar absorption feature centred at λ 2200, $W = 144 \pm 30$ Å, on the relationship W (λ 2200) with $E(B-V)$ given by Nandy *et al.*[7].

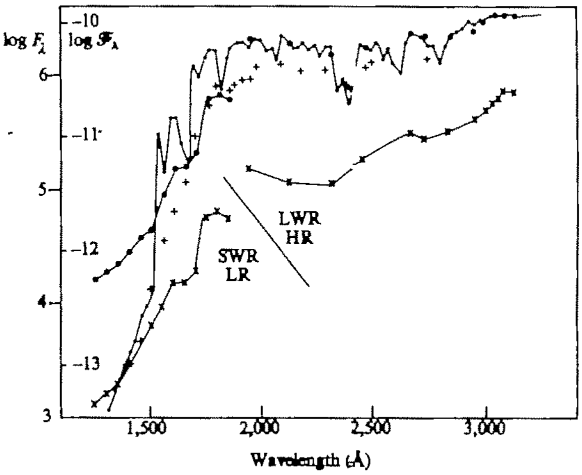

Fig. 2 The continuous flux $\mathcal{F}_\lambda$ (in erg cm^{-2} s^{-1} $Å^{-1}$) observed for Epsilon Aur (×, non-corrected for interstellar extinction, and ○, corrected for interstellar extinction with $E(B-V) = 0.30$), and that observed for Alpha Car with experiment S2/68 on TD 1 divided by 30(+) to make it comparable with that expected for Epsilon Aur which is 3.7 mag less bright than Alpha Car. F_λ is the surface flux computed for an atmosphere with parameters $T_e = 7{,}500$ K and $\log g = 1$ (●). SWP, LR, observations made in the low-resolution mode with the short wave primary camera; LWR, HR, observations made in the high-resolution mode, with the long wave redundant camera.

The continuous flux corrected for scattered light and for interstellar extinction is compared with that observed for Alpha Car (F0 Ia, $E(B-V) = 0.01$) with experiment S2/68 on TD 1 (ref. 8) and with the theoretical surface flux computed by Kurucz et al.[9] for $T_e = 7{,}500$ K and $\log g = 1$, solar composition (a model which reproduces the visual spectrum well[10]) (Fig. 2).

The ratio

$$r_\lambda = \frac{\mathcal{F}_{\lambda\,\mathrm{obs}}}{\mathcal{F}_{\lambda\,\mathrm{pred}}} = \frac{R_A^2 F_{\lambda A} + R_B^2 F_{\lambda B}}{R_A^2 F_{\lambda A}}$$

(where $\mathcal{F}_{\lambda\,\mathrm{obs}}$ is the observed flux at Earth corrected for interstellar extinction, and $\mathcal{F}_{\lambda\,\mathrm{pred}}$ is the predicted flux at Earth computed assuming that Epsilon Aur has the same energy distribution as Alpha Car; $F_{\lambda A}$ is the flux emitted by a stellar atmosphere with $T_e = 7{,}500$ K, $\log g = 1$ computed by Kurucz *et al.*[9]; $R_A = 10^{13}$ cm is the radius of the primary as indicated by the circumstances of the eclipse) has the following values:

$r(\lambda\ 1300) = 50 \pm 30$

$r(\lambda\lambda\ 1400\text{–}1500) = 8.1 \pm 0.4$

$r(\lambda\lambda\ 1550\text{–}1600) = 2.3 \pm 0.3$

$r(\lambda\lambda\ 1650\text{–}3100) = 1.1 \pm 0.3$

From these data we can estimate that the effective temperature and the radius of the companion have the following values:

$$T_B = 15{,}000 \pm 3{,}000\ \text{K}, \quad R_B = 10^{11} \pm 0.5 \times 10^{11}\ \text{cm}$$

The absorption line spectrum confirms that the companion is not very hot: λ 1640 He II and λλ 1548–1550 C IV are not present, while λλ 1394–1402 Si IV are. All the strongest lines of C I, C II, C III, N I, O I (in emission), Si II, Si III, Si IV, P II, P III, S II, S III, and of once- and twice-ionised atoms of the iron group are present.

The strong emission of O I at λ 1302 indicates the existence of an envelope where the hydrogen is mostly ionised, because H I and O I have almost identical ionisation potentials. Lyβ emission can overpopulate the upper level of λ 1025.77 O I, which has almost the same high EP as Lyβ; then by cascade, emissions at λ 8446 and λ 1302 can be explained[11,12].

The companion is therefore a B-type star falling on or slightly below the main sequence, whose absolute bolometric magnitude is about 7 mag fainter than that of the primary. As the system is not close, the presence of the ring cannot be explained by mass exchange between the two stars. The companion may be a past nova, and the ring may have formed with gas expelled during an outburst. Absolute magnitude and spectral type of quiescent recurrent novae have values similar to those derived for Epsilon Aur B.

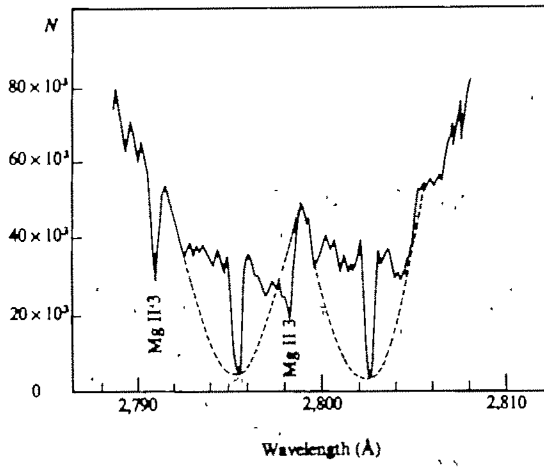

Fig. 3 The profiles of the Mg II resonance lines and the Mg II lines of multiplet 3. The ordinates are IUE counts, corrected for the background. Continuum $N = 130 \times 10^3$.

The near UV spectrum is characterised by strong absorption lines of once-ionised metallic atoms. The most interesting features are the Mg II resonance lines, which have already been observed with BUSS in 1976 but were strongly under-exposed. In the present spectrum (Fig. 3) it is evident that the central part is filled with emission, and this is cut by a strong absorption core which can be formed in the chromosphere of the F0 supergiant or be an interstellar feature, or a blend of the two. From the intensity of the Mg II interstellar lines versus distance relationship given by Lamers and Snijders[13] it seems probable that they are interstellar features. The profile of the Mg II resonance lines is very similar to that observed for Alpha Car[14], but the width of the emissions is 5.1 Å and that of Alpha Car 1.9 Å, suggesting that Epsilon Aur has a larger luminosity than Alpha Car. By plotting the width of the emission w (in km s^{-1}) on the relationship M_v against log w, given by Evans *et al.*[14], a value $M_v = -7$ is found for Epsilon Aur. The flux in the emission is about 2.5×10^{-12} erg cm^{-2} s^{-1} Å^{-1}, and after correction for interstellar extinction is 1.4×10^{-11}. The analogous flux for Alpha Car is 3.1×10^{-10}, that is 22 times that for Epsilon Aur, while the expected value due only to their difference in apparent magnitude is 30 times that of Epsilon Aur.

We thank all the staff of VILSPA Observatory for their assistance in observing and reducing the data, Dr M. Penston for calling our attention to the existence of scattered light in the far UV spectrum, and Dr P. Santin for assistance in data processing with the DEC PDP-11/45 computer system of Trieste Observatory. This work was supported by a CNR-SAS contract.

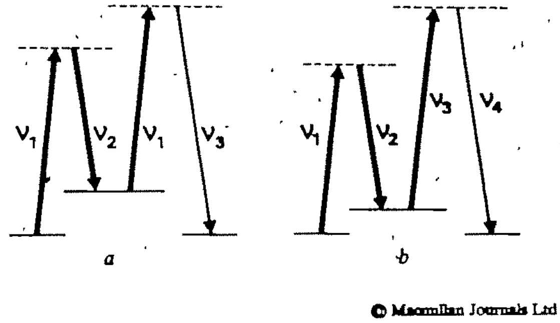
Low frequency coherent anti-Stokes Raman spectroscopy of air

THE techniques of coherent Raman spectroscopy are revolutionising the applications and scope of Raman spectroscopy. Particularly important aspects are: very high resolution spectroscopy (the Doppler width being proportional to the Raman shift of the band under study); nanosecond (and sub-nanosecond) spectroscopy, where the resolution obtained may be limited by the Fourier transform of the experimental time scale; discrimination against luminescence from the sample (whether laser induced or not). We discuss here coherent anti-Stokes Raman spectroscopy (CARS) at low frequency shifts.

The technique is briefly as follows: when a sample is irradiated with two lasers at frequencies ν_1 and ν_2 a signal is generated at a frequency $2\nu_1 - \nu_2 = \nu_3$ (see Fig. 1*a*). The signal intensity is proportional to $I^2_{\nu_1} \times I_{\nu_2}$ (where I is the incident beam intensity). When $\nu_1 - \nu_2$ is tuned to be equal to a molecular Raman active transition frequency resonance occurs. Furthermore, the signal at ν_3 is emitted to be a diffraction limited beam, in ideal phase matching conditions. There have been many reports on the use

Fig. 1 Schematic representation of *a*, three-colour CARS; *b*, four-colour CARS.



0028-0836/78/0276—0378$01.00

of CARS, notably on gases such as N_2, C_2H_2 (ref. 1) and D_2 (ref. 2). However, we know of only one low-frequency spectrum[3] (equivalent to a Raman shift of ~100 cm^{-1}). In that example the scattering medium was a liquid, while the technique we describe here is suitable for gases at pressures appreciably below atmospheric. Because CARS signals scale normally as the square of the number density, this represents an improvement in sensitivity of more than four orders of magnitude.

The lasers used for our initial experiments were:

Fixed frequency ν_1: Flash lamp pumped Nd/YAG frequency doubled to 532 nm (JK Lasers)
Tunable frequency ν_2: Flash lamp pumped dye laser (Chromatix CMX-4).

Using the above equipment, but with the Nd/YAG laser in the unstable resonator configuration, CARS spectroscopy on gases using colinear beams is routine in the range 1,000–3,200 cm^{-1}. Below 1,000 cm^{-1} problems arise due to resonant CARS signals from optical components notably in lenses and windows (where the number density is high). The CARS signal from the glass can be removed conveniently by beam expansion before beam combination and passage through the lenses and windows. Where the cell windows have to be close to the beam waist, CARS signals may be greatly reduced in one of two ways. Either the window material is selected to have no first order Raman spectrum and contains atoms of low polarisability (such as LiF) or the windows are very thin. In this way spectra may be run relatively routinely to 600 cm^{-1} for moderately scattering gases at tens of torr pressure.

Below 600 cm^{-1} the major problem lies in the collimated broad band superradiance emitted at the signal frequency by the tunable dye laser. An additional difficulty is the separation of the weak (wanted) signal from the other two intense (unwanted) colinear beams. Both of these problems become increasingly important as one moves to smaller and smaller Raman shifts.

An alternative experiment uses two tunable dye lasers (ν_1, ν_2) and one fixed frequency laser (ν_3) which is considerably removed in frequency from both the dye lasers, as shown in Fig. 1*b*. Providing ν_1 and ν_2 are well removed from ν_3 in frequency, the dye laser beams can be readily separated from the fixed frequency laser ν_3 with its associated CARS signal ν_4. Superradiance problems with fixed frequency solid state lasers are negligible compared with those from dye lasers.

This arrangement was realised experimentally with a purpose built step-tunable dye laser (ν_1) pumped by 80% of the frequency doubled Nd/YAG output. The remaining 20% of this 532 nm radiation was used as the fixed frequency (ν_3), while the Chromatix CMX-4 acted as the tunable laser (ν_2). In this way, ν_3 is particularly free from other frequencies due to the square law dependence (on the intensity of the incident beam) for the frequency doubling process.

The remaining difficulty is the separation of ν_3 from the signal. This may be achieved by using prisms or gratings of sufficient dispersion. However, for pure rotational Raman spectroscopy all bands are depolarised. In three-colour CARS (Fig. 1*a*) the polarisation of the CARS radiation follows that of ν_2. The situation is more complex in four-colour CARS[4] (Fig. 1*b*). For depolarised bands (or polarised bands where the anisotropy is large) polarisation of the CARS signal (ν_4) will be exactly perpendicular to ν_3 if the polarisations of ν_1 and ν_2 are orthogonal and ν_3 is parallel to either ν_1 or ν_2. By passing all four beams through an analysing polariser and a prism of moderate dispersion, ν_1 and ν_2 can be effectively removed and ν_3 attenuated by six orders of magnitude. The limitation in the removal of ν_3 is the birefringence of the optical components. Additional filtering of the signal with a conventional double monochromator allows the monitoring of ν_4 to approximately a shift of 40 cm^{-1}.

The success of this approach is clearly demonstrated by the pure rotational CARS spectrum of air in Fig. 2. The inset shows a higher resolution spectrum of the 60 cm^{-1} band arising from a near coincidence (~0.7 cm^{-1}) of $^{14}N_2$ $J = 6 \rightarrow 8$ and $^{16}O_2$ $J = 9 \rightarrow 11$. The resolution of 0.2 cm^{-1} is routine and 0.01 cm^{-1} could readily be achieved, although not using the CMX-4.

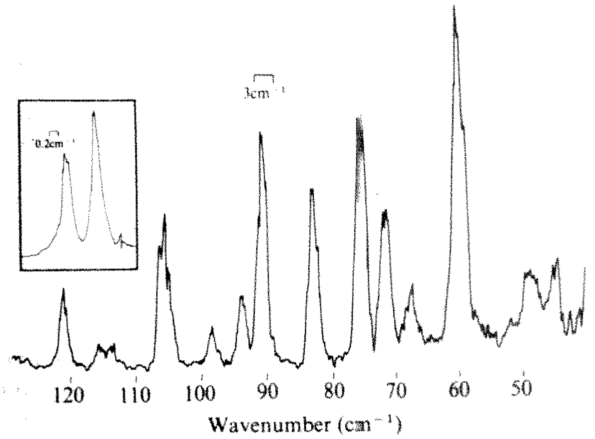


Fig. 2 Pure rotational CARS spectrum of air. Inset: the 60 cm^{-1} band under higher resolution.

For strongly polarised bands the BOXCARS approach of Eckbreth[5], using non colinear beams coupled with the present four colour system seems to be attractive.

We thank the SRC for financial support, Dr D. C. Hanna and L. Laycock for the design and construction of a Nd/YAG pumped dye laser, and Dr M. Yuratich for helpful discussions.

Trace elements in diamonds of different types

STUDIES of optical and electrical properties have shown that natural diamond can be broadly categorised into four types, types IA, IB, IIA and IIB (refs 1–3). Type IA is the most common (98% abundance)[3] and contains up to 0.34% N (ref. 16), which has been argued[5] to occur in atom pairs. Type IB diamond contains much less N, of which 1–2% occurs as single substitutional paramagnetic N. Type II diamonds contain even less N. The p-type semiconducting property of type IIB diamond is due to the presence of B (refs 6, 7), the concentration of which has been correlated with the acceptor concentration[7]. We have determined and report here the impurity contents of 23 diamonds of different types in order to investigate whether elements other than N and B contribute to the physical properties of diamond. Although there are few diamonds of each type and the statistics are therefore poor, two diamonds were found to contain an excess of Ni, while the three Type IIB diamonds possibly contained an excess of Al.

The diamonds analysed were classified into the different types using infrared and ultraviolet spectral characteristics, and

0028–0836/78/0276—0379$01.00

conductivity measurements. Diamonds 1 to 6 (Table 1) were flawless light yellow octahedra. In all the other diamonds inclusions and flaws were visible at 50× magnification under polarised light and these were removed by cutting and polishing. The individual diamonds were analysed using an established neutron activation analysis technique[4,8]. Superficial contamination was avoided by chemical etching after irradiation to remove a few micrometres of diamond from the outer surface[9]. The results are given in Table 1.

Errors vary with sample size and impurity concentration, and range from 5% at best to 40% at the limit of detection. The most reliable data are for Na, Al, Sc, Mn, Co and Ni. Because of the interest in Ni, limits of detection were calculated for this element[10]. Rare earth elements (REEs) were observed in some diamonds at very low concentrations, but no reliable quantitative determinations could be made.

Despite the care taken to remove inclusions it is clear from the trace element concentrations and their inter-relationships[8,11] that diamonds nos 4, 8, 9, 10, 18 and 20 contained mineral inclusions (Table 1). The impurities present in the rest of the diamonds were inferred to be predominantly due to submicroscopic inclusions of the parental magma[11].

Considering, for example, the relationship between Al and Mn for the 23 diamonds studied (Fig. 1), and ignoring the inclusion-containing stones, there seems to be no significant difference between types IA and IIA diamonds. This observation is supported by more detailed scrutiny of the data in Table 1, and it seems that the present data on trace element levels can contribute little to the existing body of knowledge which attributes the difference between types IA and IIA diamond to the N content, and the physical mode of its occurrence.

The data in Table 1 show that among the inclusion-free diamonds the type IIB diamonds contained the highest levels of Al. A plot of the Al against Mn contents (Fig. 1) shows that the Al content is in excess of that expected from the submicroscopic inclusions of parental magna inferred to be present in all diamonds[11]. That this is an Al excess and not a Mn deficiency can be shown by comparing the Al with other lithophile elements, for example, the Al to Sc ratio is ~3,000 in the parental magma (H.W.F. unpublished data). It is difficult to determine the real significance of the Al excess in type IIB diamonds because comparable Al excesses are occasionally found in other types of diamond, for example, nos 2, 3 and 7 (Table 1). There has been controversy over the part played by Al in semiconducting diamond[12], and it has been suggested that Al

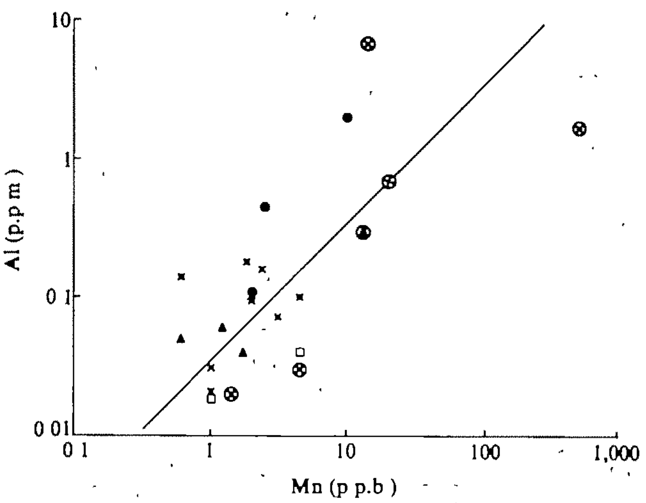

Fig. 1 Aluminium and manganese content in diamonds of different types: ×, type IA; □, type IA; △, type IIIA; ●, type IIB. Points circled are from diamonds containing inferred mineral inclusions. The composition line shows the Al:Mn ratio of ~35 inferred by Fesq et al.[11] for the parental magma (p.p.b., parts per 10^9).

Some elements were determined in only a few of the diamonds. Diamond no. 8 contained 20 p.p.m. Ca, Diamonds nos 9 and 18 contained 0.5 and 1.1 p.p.m. Cu, respectively. REE's were observed in diamonds nos 4, 8, 10, 18 and 20.

*Parts per 10^9.

†Diamonds with inferred mineral inclusions.

could act as a getter for N (ref. 13), thus preventing compensation of B. A larger number of type IIB diamonds is being analysed for B, N and Al in order to clarify any secondary role which may be played by Al in semiconducting diamonds.

As Table 1 shows, two diamonds with types IB character (Nos 11 and 12) have unusually large Ni:Co ratios (2,500 and 1,400) compared to all other diamonds. With the exception of these two diamonds, the Ni:Co ratios in the diamonds analysed here ranged from <15 to 118. This range includes the ratios for those diamonds where Ni was not detected but was assumed to be present at the limit of detection. This range is in good agreement with that found previously where Ni:Co ratios ranging from 5 to 110 were found in a large suite of diamonds[4] (note error in ref. 11, Table 3). Those diamonds were not typed but probably contained predominantly type IA diamonds, the most common type. One exception found in that work was for a 1 g sample containing about 15 orange diamonds from the Premier Mine, Transvaal. This sample, which probably contained some type IB diamonds, had a Ni:Co ratio of 250, which again is unusually high. These ratios should be compared to those inferred for the parental magma: silicate phase ~15; sulphide phase ~40 (H.W.F. unpublished data).

In this case it is more difficult to prove which of the two elements is anomalous. However, it is unusual for the Fe:Ni ratio to be <1. In the data obtained from the analysis of over 100 samples of diamond only nine cases were found where the Fe:Ni ratio was <1, the lowest being 0.14. From the calculated limits of detection for iron in diamonds nos 11 and 12, the maximum possible ratios are seen to be 0.05 and 0.14, respectively, which are unusually low[4]. Because both the Fe and the Co contents are low compared to that of Ni in diamonds nos 11 and 12 only, it suggests that these diamonds are characterised by a net Ni excess and are therefore unusual.

Two arguments can explain the high Ni:Co ratio found in these two diamonds. First, it could be due to submicroscopic inclusions of a Ni-rich, Co-poor, phase. The low levels of lithophile elements (for example, Al and Sc) found in these two diamonds suggests that any possible Ni-rich phase should be a sulphide. Alternatively, it has been shown[14] that Ni can occupy lattice sites in synthetic diamonds grown from Ni-rich melts, where Ni acts as a catalyst. Klyuev *et al.*[15] regard the morphology of type IB diamond, and the presence of paramagnetic nitrogen, as indicating formation in a low-temperature environment. If this is so then the availability of Ni as a catalyst could be essential to their formation. Unfortunately the two Ni-rich stones cannot be unambiguously classified: diamond no. 12 is dominantly type IB with some admixture, while diamond no. 11 is most likely mixed type IB and type IIA.

These speculations reflect the need for further measurement of the Ni:Co ratios in type IB diamonds. High purity diamonds are necessary as the presence of inclusions with a 'normal' silicate or sulphide composition will tend to mask any unusual Ni:Co ratio. A search for Ni in the lattice of type IB diamonds using other methods of analysis could help clarify the possible role of Ni in the formation of type IB diamonds.

A reduction in $^{87}Sr/^{86}Sr$ during basalt alteration

HYDROTHERMAL alteration of basalts on the ocean floor has been reported to cause a general increase in the $^{87}Sr/^{86}Sr$ ratio of the basalts[1,2]. Results are presented here from Mull in the British Tertiary province which suggest strongly that hydrothermal alteration in such discrete magmatic centres may actually cause a reduction in the $^{87}Sr/^{86}Sr$ ratios of some basalts. Preliminary data indicate that the $^{143}Nd/^{144}Nd$ ratios are unaffected.

Oxygen isotope studies[3,4] of Tertiary igneous rocks from Skye, Mull and Ardnamurchan have demonstrated that large scale hydrothermal systems were established in these areas at the time of igneous intrusion. On both Skye and Mull hydrothermal aureoles extend for up to 6 km from the central intrusive complexes into the surrounding basalts. Within these regions greenschist-facies mineral assemblages have been formed and the rocks are depleted in ^{18}O due to interaction with hot meteoric waters.

The samples selected for this study are from a quarry 3.5 km east of Salen, which lies within the epidote zone of the central aureole on Mull. A hydrothermally altered lava flow is exposed which shows a gradual transition from dark basalt in the massive flow interior to green 'spilitic' material at the margin. In the centre of the flow only olivine has broken down; it is pseudomorphed by chlorite and oxides and the groundmass is rich in chlorite. With increasing alteration plagioclase and the titanomagnetites are replaced by albite, sphene, and calcite and/or epidote. Only at the margin of the flow is pyroxene completely broken down (Fig. 1) and an assemblage of chlorite, albite, quartz, amphibole, epidote, and sphene occurs in which none of the original mineralogy is preserved. Within this flow Al, Ti, Zr, Nb, Y, P, and the rare earth elements preserve almost constant ratios except at the margin where slight loss of *P* and the light rare earths (La, Ce) is observed[5–7]. This is accompanied by variations in the other major and trace elements; particularly, drastic leaching of Ca. Sr isotope analyses were carried out on 10 whole rock samples across the lava flow and on leached pyroxene separated from the flow centre. A secondary mineral pod consisting of zeolite, calcite, and albite surrounded by chlorite which formed immediately above the base of the overlying lava flow, and two discordant veins were also analysed to determine the $^{87}Sr/^{86}Sr$ ratio of at least some of the hydrothermal fluids.

The results are presented in Table 1. Within the lava flow the age-corrected initial $^{87}Sr/^{86}Sr$ ratios range from 0.70467 near the top of the flow to 0.70519 at the base of the sampled section (Fig. 1). The decrease in $^{87}Sr/^{86}Sr$ towards the top of the flow is accompanied by an increase in the degree of visible alteration and a decrease in Fe^{3+}/Fe^{2+}. Sr contents range between 270 and 440 p.p.m. in the more altered samples but seem to be much less variable near the centre of the flow.

$^{143}Nd/^{144}Nd$ ratios were determined on two samples using the technique described in ref. 8. The two samples show very

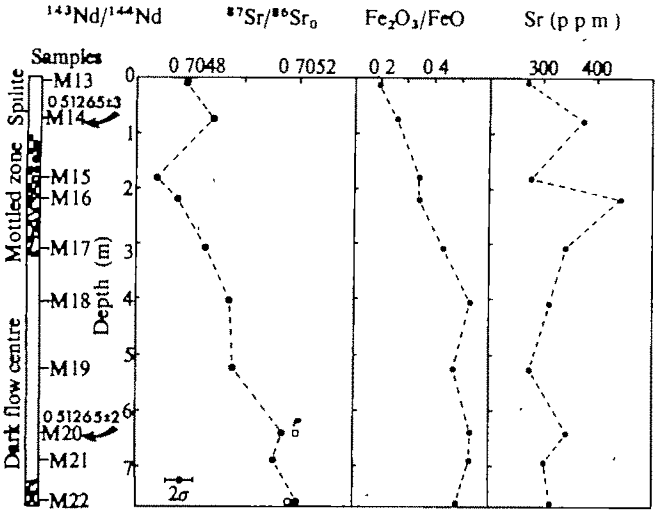

Fig. 1 Variations in ^{87}Sr/^{86}Sr$_0$, Fe$_2$O$_3$/FeO, and Sr p.p m across 7.5 m of an individual lava flow, near Salen, Mull. The degree of hydrothermal alteration is illustrated and M22 shows the onset of increased alteration approaching the base of the flow. Open symbols denote samples leached in 6M HCl; □, pyroxene; ○, whole rock.

different degrees of alteration but in sharp contrast to their variable ^{87}Sr/^{86}Sr ratios (Fig. 1) their Nd compositions are indistinguishable analytically (M14, 0.51265±3; M20, 0.51265±2; 2σ errors).

To investigate further the Sr isotope geochemistry, pyroxene was separated from M20 and it and some whole rock powders were subjected to leaching experiments. Leaching was carried out with 6M HCl in sealed Teflon bombs for 14 h at 130°C (ref. 9). X-ray analysis of the whole rock powders before and after leaching showed a marked increase in the concentration of pyroxene and to a lesser extent plagioclase, due to the dissolution of secondary minerals such as chlorite. Analysis of the residue after leaching should therefore provide ^{87}Sr/^{86}Sr ratios close to the pre-alteration composition of the lava flow.

The pyroxene has an age-corrected initial ^{87}Sr/^{86}Sr ratio of 0.70519 while that of the leached whole rock sample M22 is 0.70516 (Fig. 1). Rb and Sr concentrations for the leached residues from M18, M19, and M20 are not available but they all have significantly higher present-day ^{87}Sr/^{86}Sr ratios than the unleached samples. This indicates that the altered material tends to have lower ^{87}Sr/^{86}Sr ratios than the fresh basalts.

The leaching experiments and the observed decrease of ^{87}Sr/^{86}Sr with increasing bulk rock alteration and decreasing Fe^{3+}/Fe^{2+} (Fig. 1), all suggest that hydrothermal alteration of this lava flow resulted in a general reduction in ^{87}Sr/^{86}Sr. The composition of the separated leached pyroxene provides the best estimate of the primary composition of the magma (~0.7052). The two ^{143}Nd/^{144}Nd results, however, indicate that the lava was isotopically homogeneous when it crystallised, and that Nd was not affected significantly by the hydrothermal alteration (see also ref. 7).

Evidence that the fluids responsible for the hydrothermal alteration did have low ^{87}Sr/^{86}Sr ratios is provided by the results on secondary minerals (Table 1). The secondary pod from the overlying flow gave values of 0.70421 and 0.70427. The two vein samples M64 and M24 which cut the flow and therefore represent later stage fluids have ^{87}Sr/^{86}Sr ratios of 0.70467 and 0.70521. This may also indicate a rise in the value of the ^{87}Sr/^{86}Sr ratio of the fluids with time at this locality.

Forester and Taylor[4] have suggested that the alteration within the hydrothermal aureole on Mull was caused by interaction with fluids having δ^{18}O values of about −11 to −12. Such depleted oxygen compositions are suggestive of meteoric water in high latitudes, but at least in the area of this study the fluids are also apparently characterised by low ^{87}Sr/^{86}Sr ratios (< 0.7048). This clearly rules out interaction with Moinian basement[10], or Tertiary intrusives such as the Glen Cannel and Loch Usig granophyres which have initial ^{87}Sr/^{86}Sr ratios of 0.7094±3 and 0.7135–0.7162 (refs 11 and 10) respectively. Sources of the unradiogenic Sr in the fluids are either unconfirmed but possible granulite facies basement, or, much more likely, the basalts themselves.

We envisage that interaction of meteoric water with hot volcanic rocks caused the chemistry of the resultant fluids to be buffered by that of the basalts. As 70% of the fresh volcanic rocks from Mull analysed by Beckinsale *et al.*[11] have ^{87}Sr/^{86}Sr ratios <0.7043, the fluids in this area are likely to have similar ^{87}Sr/^{86}Sr ratios. Their interaction with basalt of Sr composition 0.7052 will therefore result in a reduction in ^{87}Sr/^{86}Sr in the

‡ Initial Sr composition calculated assuming an age of 60 Myr and $\lambda = 1.39\times10^{-11}$ yr^{-1} for ^{87}Rb decay.

Results in brackets indicate that they were determined on samples which had been leached in 6M HCp(see text) more altered material (see Fig. 1). Moreover as no systematic variation in Sr content in the altered rocks was observed (Fig. 1) it seems that Sr isotope exchange took place without net addition or removal of Sr. Finally these results may provide some constraints on our models for the size of water circulation 'cells'. They suggest that the Sr composition of the fluids in this area was not affected significantly by interaction with either 'old' basement (perhaps 0.5 km beneath the present erosion surface) or Tertiary intrusive rocks which crop out only 1.5 km to the south.

Field measurements of the rheology of lava

KNOWLEDGE of magma rheology is required to understand many igneous and volcanic processes. Viscosities of silicate melts can be estimated from their chemical composition and temperature using empirical methods[1-3]. However, the validity of these estimates has been established only at supraliquidus temperatures where common igneous melts behave as newtonian fluids. Recent experimental evidence from field and laboratory studies[4-7], has demonstrated that, at subliquidus temperatures, some magmas behave as non-newtonian fluids due to the presence of dispersed crystals and gas bubbles and possibly as a consequence of structuring in the silicate melt. We present data here on the rheological properties of small lava flows which were erupted on Mount Etna in 1975. These data were obtained by field measurements using a new field viscometer[8], a shear vane attached to a torque wrench, a conventional penetrometer and various field techniques for estimating rheological properties from the dimensions of lava flows.

Published field measurements of lava rheology have been obtained using various techniques[4,9-12] which, with the exception of one, assume newtonian rheology and also fail to take account of marked thermal (and therefore rheological) gradients which develop at the margins of active flows. The most accurate lava rheology data to be published[4] indicates that the tholeiite in the Makaopuhi lava lake in 1968 was pseudoplastic with yield strengths of 70 and 120 N m^{-2} measured in two experiments and plastic viscosities of 750 and 650 Pa s respectively. The rotating shear vane used for these measurements, however, is suitable only for stable encrusted lava lakes. Because moving lava flows are generally encountered during volcanic eruptions, alternative methods of measuring lava rheology are required. We describe here several techniques with different levels of sophistication which can be used to measure rheological properties of active lava flows.

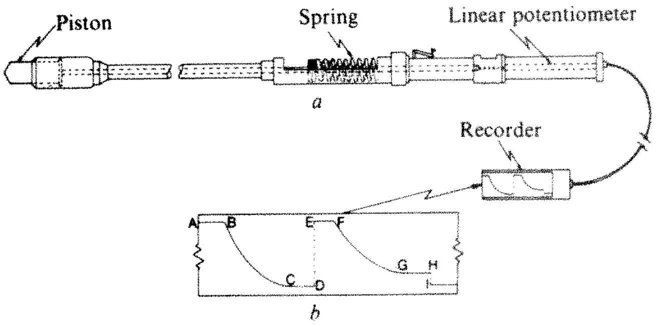

Fig. 1 The Mark 2 viscometer and recorder are shown in (*a*) while an enlarged view of a typical trace from the recorder is shown in (*b*). The Mark 2 is 2 m long and is constructed from high temperature stainless steel. The stainless steel spring used on Etna had a strength of 0.155 N m^{-1}. The recorder, a Cambridge type 72125 single speed hot wire recorder, had a chart speed of 0.0245 m s^{-1}. The traces in (*b*) are characteristic of a newtonian fluid (A–D) and a Bingham material (E–H). For a newtonian fluid, the horizontal distance between A and D is a function of newtonian viscosity. For the Bingham material, GH corresponds to the equilibrium position of the piston in the material; thus the vertical distance HI is related to the dynamic yield strength of the material.

The Mark 2 field viscometer (Fig. 1) is essentially a penetrometer, but differs from conventional penetrometers in that shearing is confined mainly to the region adjacent to the advancing piston in the interior of the lava. Shearing resistance is not affected by the more viscous cool flow margins as with a conventional penetrometer. In the field the instrument, which is made from BS 321 S20 stainless steel, is preheated by repeated insertions into lava until the temperature of the 'active' end is comparable to that of the lava. It is then inserted to the required depth in the lava and the piston released. A controlled but variable shear rate around the advancing piston is obtained using a compressed spring as the propelling force (Fig. 1) and piston velocity, at a given axial force, is monitored by a linear potentiometer on a hot wire pen recorder. The recorder output is readily converted to shear stress–shear rate data[8]. The yield strength of the lava is obtained directly from the residual force applied by the piston at zero piston velocity (Fig. 1). Thus complete rheological data for the lavas over a wide range of shear rates can be obtained (Fig. 2).

Two additional instruments were used to measure yield strengths on Etna[8]. One is a stainless steel shear vane attached to a torque wrench. After preheating, the vane is inserted into the lava and the torque is increased until the shear vane begins to rotate. Shearing resistance along the shaft is obtained by repeating the measurement at the same depth with the shear vane removed. Thus viscous resistance due to shearing within the lava surrounding the shear vane (and hence the yield strength of the lava) is readily calculated. The third instrument to be used on Etna was a penetrometer. This comprised a 2 m long, 3 cm diameter stainless steel rod, and a pressure transducer which was used to apply a known pressure during insertion. Two other methods were used to acquire rheological data on Etna. These involve (1) measuring the width of newly-formed levees[7,13]; and (2) measuring the dimensions of small lava flows[13,14]. Temperatures were measured during each rheological measurement using a Cr–Al thermocouple.

Rheological data and accompanying temperatures measured on Etna are given in Figs 2 and 3. Figure 2 shows the shear stress–shear rate data for a typical measurement using the Mark 2 viscometer. This measurement was made 3 m downflow from an active bocca at a depth of 0.2 m. The temperature of the lava

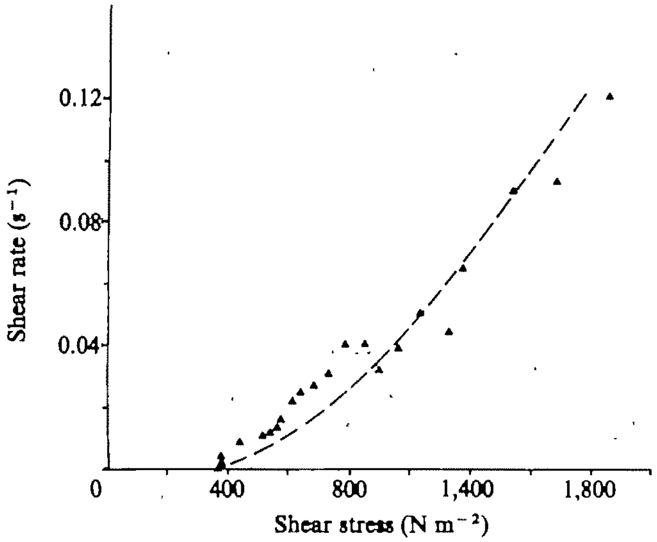

Fig. 2 Rheology of the 1975 Etna lava at 1,086 °C It can readily be seen that the Etna lava is pseudoplastic with a yield strength of 370(±30) N m^{-2}. If the curve is approximated to a Bingham relationship, the Bingham viscosity is 9,400 ± 1,500 Pa s.

at that point was 1,086 ± 3 °C. The results in Fig. 2 confirm that, at this temperature, the Etna lava had a yield strength of 370 ± 30 N m^{-2}, and it behaved in a pseudoplastic manner. If the curve is approximated to a Bingham relationship, the Bingham or plastic viscosity is 9,400 ± 1,500 Pa s at shear rates <0.15 s^{-1}. Lower plastic viscosities at higher shear rates are possible.

The yield strength of the interior of the 1975 Etna lavas was also calculated using the shear vane, the penetrometer and dimensions of initial levees[8]. Yield strengths measured by these methods are comparable with those calculated using the Mark 2 (Fig. 3), although the consistently higher values obtained by the conventional penetrometer suggest that shear resistance due to the cooler, outer margins of lava flows significantly affected the apparent yield strengths measured using this type of instrument. The relationship between the yield strength of the interior of the 1975 Etna lava and temperature are given by curve 1 in Fig. 3. Four estimates of yield strength were obtained from flow front dimensions. These measurements record the average or 'bulk' rheological properties of the lava which has a low yield strength in the hot interior and a high yield strength in the cool margins. The relationship between the bulk yield strength and the temperature of the isothermal interior of the Etna lavas is shown by curve 2 in Fig. 3. From curves 1 and 2 it seems that the bulk yield strengths of small advancing Etna lava flows are ~2.5 times greater than their hot interiors.

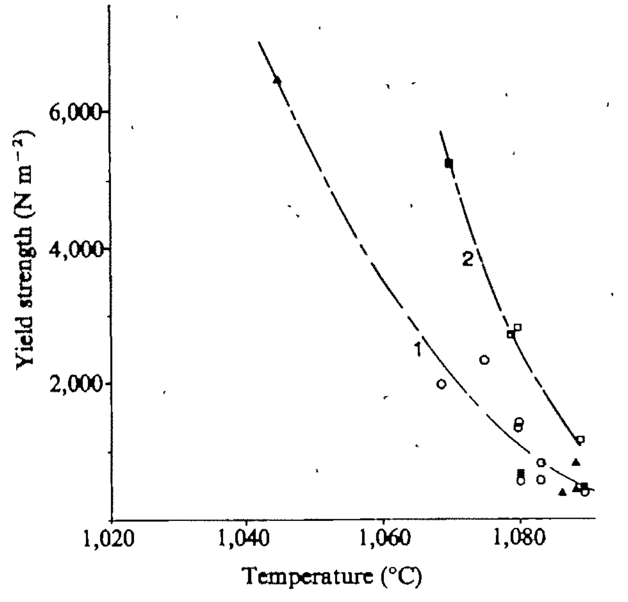

Fig. 3 Relationship between the central temperature and yield strength of specific points along several 1975 Etna lava flows. Curve 1 indicates the trend for the interior of lava flows, while curve 2 indicates the possible relationship for the fronts of advancing flows. It is postulated that curve 1 will tend, asymptotically, to a yield strength of zero at supraliquidus temperatures. ▲, Mark 2; ○, Shear vane; △, penetrometer; □, flow front data; ■, initial levee data.

Etna was the first volcano for which non-newtonian behaviour of lava was proposed[15]. Our results confirm that, on eruption, the 1975 sub-terminal Etna lavas were pseudoplastic with a yield strength. Compared with the tholeiite in Makaopuhi lava lake in 1968[4], the Etna lava flows had higher crystal contents (modal analyses: 35% for Hawaii and 45% for Etna) and lower effusion temperatures (1,135 °C for Hawaii and 1,090 °C for Etna). The higher crystal concentrations and lower effusion temperatures of the Etna lavas are, at least partly, responsible for the higher yield strengths and plastic viscosities of the Etna lava flows[3].

For the volcanologist, non-newtonian behaviour of lava has many implications, both in understanding the flow behaviour of lava flows and in interpreting their morphology. For example, as the apparent viscosity of a pseudoplastic material decreases with increasing shear rate, a fast-moving lava flow will seem to be more fluid than when it moves more slowly. Consequently, if the viscosity of lava flows is calculated from the commonly used Jeffrey's equation[12], Fig. 2 shows that lower apparent viscosities will be calculated for faster-moving lava flows.

For the petrologist, magma rheology is of considerable importance in many processes, such as ascent of magmas, crystal settling[16,17], convection in magmas and xenolith transport[18]. Depending on the reasons for the development of a yield strength in magmas, some, or all, of these processes may be affected by the possible non-newtonian properties of magmas. If the yield strength results entirely from the interaction effects of the phenocryst phase, then only relatively large-scale processes will be affected by the yield strength, for example the settling of xenoliths. On the other hand, if the yield strength results from the formation of a microcrystalline mosaic[19], liquid–liquid immiscibility[20], or structural reorganisation of the melt[21], small-scale processes will also be affected. In particular, crystal settling will not be possible in certain magmas. The reasons for the development of a yield strength in lava flows are investigated more fully elsewhere[22].

Effect of degassing on rheology of basaltic lava

BEFORE eruption, most basaltic lava flows lose volatiles, either by Hawaiian—or Strombolian-type fire-fountaining. This gas loss may be of fundamental importance in explaining the observed non-newtonian characteristics of many lava flows. The model proposed here also helps to explain the variations in the surface morphology of many basaltic lava flows.

The loss of most common volatile components increases the viscosity of silicate melts[1,2], and this has been cited as a cause of moderate changes in the viscosity of lava flows[3]. However, an even more important consequence of gas loss is a sudden undercooling of the lava triggering an all-pervasive growth of quench crystals in the lava. This process leads to a rapid increase in viscosity and the development of a high yield strength in the lava.

Degassing of magma leads to undercooling of lava by three processes. First, decompression of the gas phase cools the total magma system adiabatically. For water, $\sim$20 °C cooling occurs per 1 wt% released (ref. 4 and L. Wilson, unpublished calculations). Second, the solution of gases suppresses the liquidus of a melt and alters the order of appearance of mineral phases[5]. Hence, sudden gas loss upsets equilibrium and the melt will generally become undercooled with respect to its anhydrous liquidus. Experimental studies on water solubility and the effect of increasing water pressure on liquidus temperatures[2,5,6] indicate that common types of basalt which contain 1% water would be saturated at 300–400 bar. Such a basalt would be undercooled, by this process, between 30 and 50 °C, if brought rapidly to the surface and then degassed. Carmichael *et al.*[7], on the basis of thermodynamic arguments, also deduced that the crystallisation temperatures of silicate phases would increase on volatile loss. Third, fire-fountaining results in some mixing with the atmosphere and opportunity for radiative heat loss. Some or all of this cooled magma may then be erupted as a lava flow. Swanson and Fabbi[8] have shown that fountain height increases with greater volatile content in Hawaiian fountains which fed lava flows. Consequently, the high fountains associated with large volatile contents would result in increased atmospheric cooling. Data from chilled pillow margins indicate that mid-ocean ridge basalts have water contents ranging from 0.25 to 1.0% with a tendency for alkali basalts to have higher contents than tholeiitic basalts[9–11], whereas basalts from calc-alkaline island arcs and back-arc basins seem to contain even higher water contents[12,13]. Taking a mean water loss from basalts of 1 wt%, we estimate that, as a result of the above three mechanisms, this loss would, typically, cause the lava flow to become undercooled by at least 50 °C. The amount of undercooling will increase with increasing gas loss.

Kirkpatrick[14–16] has shown that crystal nucleation and growth rates both increase with higher values of undercooling of a melt, attain a maximum at several tens of °C, and then decrease. For example, maximum nucleation and growth rates in basalt occur at 50–100 °C undercooling, that is, the same range of undercooling which we predict results from gas loss in many basalts. From Kirkpatrick's studies we estimate that plagioclase crystals will grow at rates of 0.1–1.0 μs^{-1} in a lava undercooled by 50 °C. Using a conservative value of 0.1 μs^{-1}, a 20 μm crystal could grow in 3.5 min. Growth and nucleation will continue until the residual melt has attained equilibrium. With large undercoolings the rapid growth of an extensive mosaic of crystallites can be anticipated in the early stages of flow. It also follows that strongly undercooled lavas (high original gas content) will require more extensive crystallisation to re-establish equilibrium at the extrusion temperature. As basalt lava flows commonly have emplacement times of hours, days or even weeks, gas loss thus results in an all-pervasive growth of quench crystals in the early stages of flow.

This mechanism is, therefore, far more effective in changing lava rheology than atmospheric cooling which penetrates into lavas only slowly because of their poor thermal conductivity[18–23]. In addition, crystallisation changes the composition of the residual melt which, in most cases, would become more siliceous. This effect, together with the sudden appearance of crystal dispersants and the accompanying loss of volatiles, would result in a greatly increased viscosity. More important, the lava would develop a yield strength. An aphyric magma which, before eruption, may have behaved in a newtonian manner will change to non-newtonian behaviour (develop a yield strength) as quench crystallisation takes place. A lava containing many phenocrysts will increase both in yield strength and viscosity.

Several morphological features of lava flows have been interpreted as resulting from non-newtonian rheology[18,24,25]. The formation of levees and channels and the ability of lavas to cease to flow on steep slopes has been attributed to the yield strength of lavas[18,25]. The formation of *aa* surfaces has been interpreted as being due to the inability of surface tension forces to overcome the yield strength[18].

Although lava flows with *aa* surfaces and levee and channel morphology are characteristic of high yield strength lavas, pahoehoe surfaces have also been observed forming on similar lavas, for example, Etna, 1975 (refs. 20, 23). On Etna the main factor controlling the type of lava which formed was effusion rate, pahoehoe surfaces forming on the low effusion rate lava flows. However, this generalisation cannot be extended to all other volcanoes as pahoehoe surfaces can also form on extensive flows with high inferred effusion rates[26]. Apparently therefore, when lava flows have a moderate to high yield strength, pahoehoe lavas form only at low effusion rates, whereas *aa* lavas form when effusion rates exceed a critical value (2×10^{-3} $m^3 s^{-1}$ on Etna in 1975). On the other hand, when lavas behave as newtonian fluids, or when their yield strength is low, pahoehoe flows form, even at high effusion rates. Although the yield strength of the Etna lavas results, at least partly, from their high phenocryst content, certain flows with a low phenocryst content show features indicative of a high yield strength. Examples are the 1961 Askja basalt lava[27] and the 1875 Sveinagja basalt[28].

These paradoxes in the morphology of basalts can be resolved by the mechanism outlined here. Magmas with high volatile contents will produce strongly undercooled degassed lava. These lavas will develop a high yield strength due to quench crystallisation and will form channelled *aa* flows except at low effusion rate. Magmas with low volatile contents will not be strongly undercooled so will not change rheology substantially on extrusion; they would have either low yield strengths or even behave as newtonian fluids. Formation of pahoehoe flows, even with high discharge rates, would result. Evidence for high volatile content is indicated in the Askja and Sveinagja eruptions directly, by the intense fire-fountaining observed and, indirectly, by the evolved nature of the basalts indicating extensive fractionation of anhydrous phases[28]. It is interesting that the 1961 Askja lavas turned from *aa* to pahoehoe flows later in the eruption, when the intensity of fire-fountaining waned.

The most sluggish basalts are commonly found in island arc settings. These basalts are generally much more viscous than basalts associated with the spreading environments. They invariably produce *aa* or block lava flows and are usually accompanied by violent fire-fountaining, for example, the 1971–72 eruption of Villarica, Chile. Calc-alkaline basalts are

0028-0836/78/0276—0385$01 00

generally believed to have high water contents[12,13,29] compared with other common basalt types. Our proposal qualitatively explains these relationships. These basalts are more strongly undercooled after gas loss and consequently have much higher yield strengths and apparent viscosities.

There are several implications of these proposals. First, models of lava flow movement will be required to consider quench crystallisation due to gas loss as a major cause of downflow changes in rheology. Second, the rheology of active lava flows will generally not reflect the rheology of the magma before eruption, and there is a fundamental change in rheology accompanying gas loss. Hence, although many lava flows are non-newtonian this does not necessarily imply that all ascending magmas are non-newtonian. Finally, deductions based on the yield strength of lava from studies of flow morphology cannot be related simply to magma composition[18,30], but must also be related to gas content.

Pre-ceramic maize on the north-central coast of Peru

An archaeological site, located near the beach line in a desert part of the Huarmey Valley, 292 km north of Lima, in the department of Ancash, province of Casma, district of Huarmey, 78°10′21″W, 10°02′45″S in Peru, was first observed by D. H. Kelley in 1957. It had been previously found by E. P. Lanning who identified it as a pre-ceramic site. It was first designated Huarmey North 1 and it appears as such in previous literature; we are assigning it its real name, Los Gavilanes. We report here ^{14}C dating of maize plant, tassel and cob material from this pre-ceramic site in Huarmey, Peru, at 3,750 ± 100 yr BP.

Charred stones of an underground structure where the associated maize material was found has a date of 4,800 ± 500 yr BP, by thermoluminescence analysis. The corn material was identified as being almost entirely of the Proto-Confite Morocho race, a modern counterpart of which exists today only in the central highlands of Peru. No evidence was found of maize races originating outside of the central Andean region.

A first sounding made by Kelley produced some maize material, which was examined by P. C. Mangelsdorf. Further excavations produced 238 different maize cob, tassel and plant parts. These findings were in a pre-ceramic context[1].

^{14}C measurements made on the maize material gave erratic results, which made the validity of the dating doubtful, so that a preliminary report[2] gave only general information, and no dating. It was found later that corn itself is an inadequate organic material for carbon dating, because growing corn has a most unusual rate of adsorption of ^{14}C and ". . dates of maize remains are known to be consistently too young . . . . This is due to the fact that *Zea mays* together with many other plants (mainly grasses) from semi-arid and arid regions utilise the recently discovered 4-carbon or Hatch–Slack photosynthetic pathway and not the more widespread 3-carbon or Calvin pathway for carbon dioxide fixation. Such C-4 species are not common in temperate regions; the syndrome generally constitutes an adaptation to a hot and dry environment" (ref. 3). It was also found that the technique of handling and treating the maize material presumably had not been appropriate to eliminate contamination by masses of crystallised carbonates which were later found adhering to the surface of many corn cobs at the site, and which could have obscured the radio-carbon results.

In 1974, with support of the Royal Ontario Museum of Canada, a new excavation was made, which yielded the results presented here and which permitted us to re-evaluate earlier information[2] and prepare a new report[4]. The site is located on the right of the Huarmey river banks, bordering on a fossil lagoon, which was formed between barriers of old beach lines over an old stream bed. Alyssian winds cause constant movement of shifting sands that have covered the site completely. On the surface only stone accumulations are visible, some of which could be circular structures, arranged in a confusing pattern.

The 1974 excavation was made in one of the circular structures. This was only partially completed because of the large volumes of sand that had to be removed. The excavation yielded an irregular inverted truncated cone, the walls of which are built with irregular stones, 9 m in diameter at the top, and 1.30 m deep. On the walls of this structure abundant residues of maize leaves were found. A cut on one of the sides of the structures made in order to establish its nature, showed abundant refuse mixed with the stone.

Preliminary analysis has also shown the existence of human and animal bones, predominating among the latter are a shore and sea fauna, with scarce representation of *Camelidae*, *Cervidae* and *Canidae*. There is also abundance of molluscs, primarily *Bivalvia*, *Gasteropoda* and *Amphineura*. Plant remains of *Distichlis spicata* L., *Schirpus* sp., *Tillandsia* sp., *Inga* sp., *Pachyrrizus* sp., *Schinus molle* L., *Gossypium barbadense* L., *Cucurbita* sp., *Lagenaria siceraria* (Mol.) Standl, and *Ambrosia* sp. were also found.

The artefacts found at the site are mostly lithic. Tentatively, artefacts can be distinguished as made from cobblestone: these are basically strikers, choppers and chopping tools. Circular flat pebbles, worked along the edges by unifacial percussion and whose function is still unknown, are also characteristic and distinctive. Tools obtained from flakes are scrapers, notched pieces and some cores were used like scrapers; there is also a sizeable proportion of flakes used without further preparation. There are also textile fragments made by the technique of twining, typical of the pre-ceramic period. Some coprolites were also found and these are being studied at present.

On the basis of the charcoal pieces found associated with the debris, a ^{14}C dating was obtained of 3,750 ± 110 yr BP (GIF 3564, Laboratoire du Radiocarbone du Commisariat à l'Ener-

0028-0836/78/0276—0386$01 00

gie Atomique CNRS). Charred stones of the excavated structure were dated by thermoluminescence analysis at 4,800 ± 500 yr BP (BOR 20, Laboratoire de Cristallographie et Physique Cristalline, University of Bordeux).

All evidence points to the Los Gavilanes site as belonging to the final Peruvian pre-ceramic period, that described by Lanning[5] as Pre-ceramic 6, and in which corn apparently played an important part.

Abundant maize cob, stalk and tassel material was recovered from the 1974 excavation made at the Los Gavilanes site. Nine intact corn cobs and 12 cob fragments were examined and measured (Fig. 1). They ranged in length from 2.5 to 9.4 cm, with diameters ranging from 0.7 to 1.4 cm. About 70% of the ears and cob fragments have 8 rows of kernels, with all the remainder having ten rows except one with 12 rows. The cupules of the cobs are distributed rather laxly, are rather deep, and are 2.5 mm in width and 4.5 to 6.0 mm in length, some with prominent cupule wings, pilosity of the cupules mostly low to medium, but a few with high pilosity. The kernels may have been isodiametric, about 3 mm in size, of the popcorn type, with 12 to 13 kernels in each row. The glumes are rather long, the external ones being semi-hard, coriaceous and the internal ones very soft and papery; they are either a quarter or half tunicate. Their colour is brownish red, and a few are purple (probable allele arrangement A_1A_2BP1).

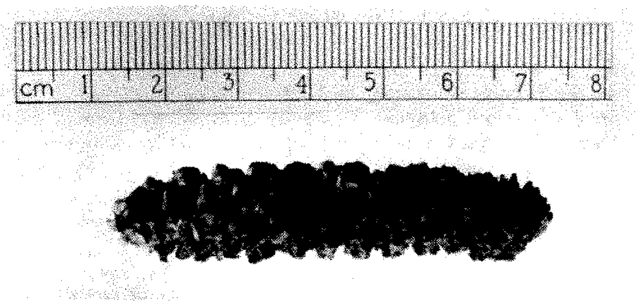

Fig. 1 Corn cob from Los Gavilanes site.

Husk material has a venation index of 7 to 9, the veins being very prominent. This is a rather high index[6], representative of primitive maize material. One of the husks exhibits a very definite purple colour. This colour type is prevalent today in the highland area of Peru, and has been shown[7] to have a definite selective advantage at high altitudes. Its presence in high frequencies in the Los Gavilanes population is a good indication of possible transfer of ancestral seeds from the highlands to the coast of Peru.

The cob peduncle is rather slender as in most highland popcorns. Stalk diameter is small, between 0.6–0.8 cm, and about 0.85 cm including leaf sheath.

Tassel fragments (Fig. 2) indicate a very lax type, such as found today in both primitive and advanced highland maize races of Peru. Condensation index of the tassels[6] ranges from 0.59 to 1.2, with the majority of the tassels falling within the shorter range of 0.58–0.8.

Unquestionably there is a single predominating maize race in this complex, an early form of Confite Morocho, designated as Proto-Confite Morocho[6]. A few cobs exhibit a fair degree of introgression of another race Proto-Confite Chavinense, better shown in one ear with some fasciation, and the only one in the cache to have 12 rows.

The abundance of plant and tassel material at the site would seem to indicate that the complete plants were harvested in the cultivated part of the valley and brought to the site tied in bundles, possibly carried on people's backs.

It is possible that the structure that has been opened was used as a silo. An interesting observation in this connection is that all the stones of the sides of the excavated structure have been burned. Similar storage pits lined with stones were found by A.G. full of ears of corn in sandy hills near Lima. The corn ears were protected from insects and rodents by filling the spaces between them in the pits with sand. Similar modern storage systems using sand were still in use in 1950 in the Huarmey Valley, and were examined at that time by A.G.

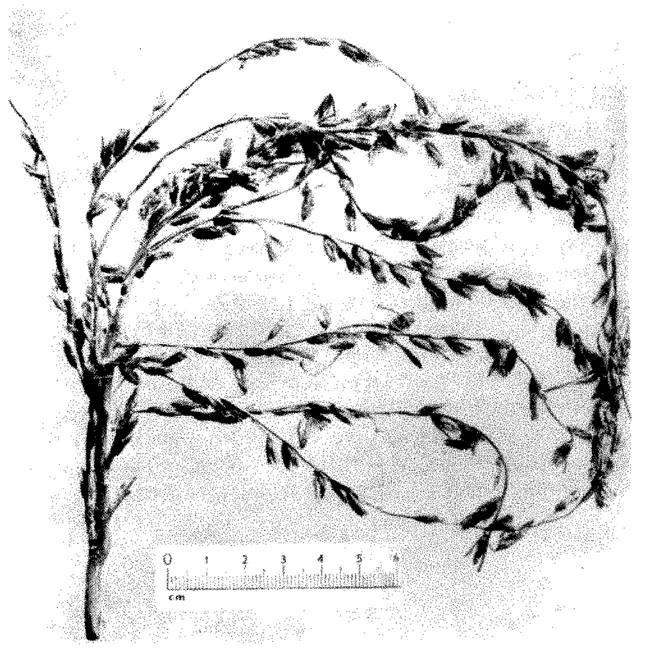

Fig. 2 Complete tassel from Los Gavilanes site.

The implication of the find is that maize was cultivated on the coast of Peru in the pre-ceramic period, about 4,000 years ago. This maize is undoubtedly related to the Confite Morocho race presently existing in the highlands of Peru and one of the most primitive races in existence. This find tends to confirm the postulation of both the origin of primitive coastal maize of Peru, as migrating from the Peruvian highlands[6], and the origin of cultivation and domestication of maize in the Central Andean region as an independent process from the domestication of maize in Meso-America[8]. There is no evidence on this site at this early period of introduction of maize resembling the primitive types that were being cultivated in Mexico contemporaneously.

We thank Virginia Popper and Elizabeth S. Wing for their help with identifications, Mario Peña for help with malacological data, Max Schvoerer for thermoluminescence dating, Georgette Delibrias for ^{14}C dating and Claude Chauchat who took part in ground research.

Lead detoxification by a copper-tolerant isopod

THE acquisition of metal tolerance by freshwater and marine invertebrates in environments polluted by mine waste in south-west England has now been established[1,2]. Generally, for invertebrates such tolerance has been shown to be specific for particular metals[1], although the literature suggests that co-tolerance may operate for copper and silver in the polychaete *Nereis diversicolor*[3] and for zinc and nickel in the grass *Agrostis tenuis*[4,5]. We show here that co-tolerance operates in the isopod crustacean *Asellus meridianus*, in which tolerance to copper seems to confer tolerance to lead. Two populations of *A. meridianus* from differing habitats are also shown to use different methods for achieving lead tolerance.

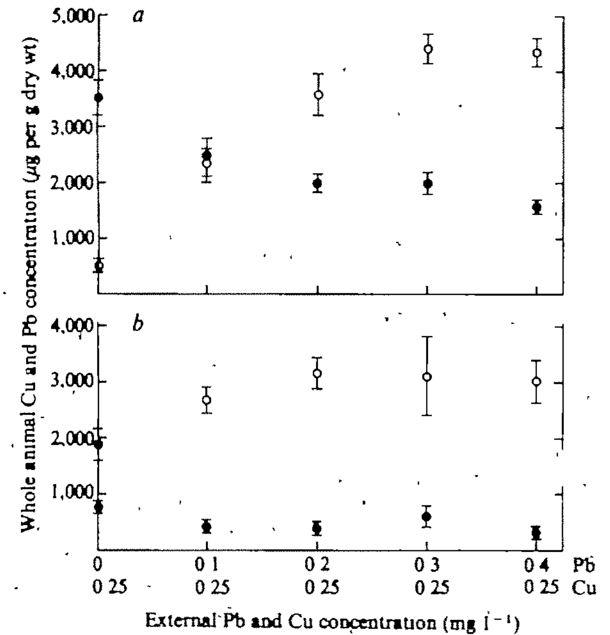

Fig. 1 The effect of increasing concentrations of lead (0.1–0.4 mg l^{-1}) and a constant copper concentration (0.25 mg l^{-1}) on uptake of copper (●) and lead (○) by *A. meridianus* from *a*, the Hayle and *b*, the Gannel, after 14 d exposure to test solutions at 15 °C±1 °C. Experimental techniques followed those described in detail elsewhere[2]. Test solutions were made up using Analar grade $CuSO_4$ and $Pb(NO_3)_2$ in a freshwater medium; solutions were renewed every 48 h throughout the experiment. Twenty animals were used at each dilution and batches of five whole animals were wet digested in Aristar HNO_3 and analysed for copper and lead with an Evans electroselenium 240 atomic absorption spectrophotometer. Each point is the mean of four batch samples; bars represent the s.e.m

In the present study, two populations of *A. meridianus* Rac were studied from two rivers, the Hayle and the Gannel, which, respectively, drain disused copper and lead mines in Cornwall, U.K. Previous work[2] had established copper and lead tolerance in animals from the River Hayle, where 'total' copper concentrations in the water range between 0.10 and 0.25 mg l^{-1} and levels of lead are low, <0.01 mg l^{-1}. A marked lead tolerance had also been observed in animals from the River Gannel, where total lead concentrations in the water range between 0.19 and 0.35 mg l^{-1}. No copper tolerance was observed in animals from the latter site, where total copper levels in the water are 0.01–0.04 mg l^{-1}.

Animals from both populations were exposed to solutions containing copper and lead alone and to mixed solutions containing the two metals in various proportions. The uptake of copper by Hayle animals is considerably reduced by the addition of increasing levels of lead, which are accumulated readily (Fig. 1*a*). Uptake of copper by the Gannel population in similar conditions is lower than that of Hayle animals and is apparently unaffected by the addition of increasing concentrations of lead. Lead uptake by these animals is also lower than that shown by the Hayle population (Fig. 1*b*).

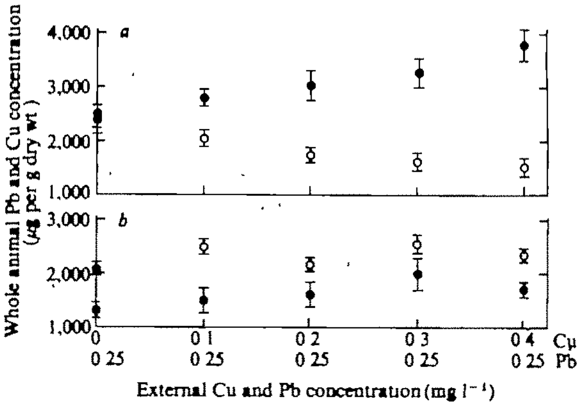

Fig. 2 The effect of increasing concentrations of copper (0.1–0.4 mg l^{-1}) and a constant lead concentration (0.25 mg l^{-1}) on uptake of lead (○) and copper (●) by *A. meridianus* from *a*, the Hayle and *b*, the Gannel, after 14 d exposure to test solutions at 15 °C±1 °C. Each point is the mean of four batch samples; bars represent the s.e.m.

When experimental conditions are reversed and animals are exposed to a constant lead concentration and increasing copper levels, uptake of lead by Hayle animals is reduced at higher copper concentrations (Fig. 2*a*). Reduction of the amount of metal accumulated by these animals is not as pronounced as in the previous experiment (Fig. 1*a*). Similarly, uptake of copper is not as marked as uptake of lead in the first experiment, suggesting that lead may be more preferentially bound than copper. Lead uptake by the Gannel population is apparently unaffected by increasing copper concentrations and copper uptake is low compared with that of Hayle animals (Fig. 2*b*).

Earlier work[2,5,6] had established that the hepatopancreas served as a principal storage organ for trace metals in isopod crustaceans. Ultrastructural and subsequent X-ray microanalytical studies of the hepatopancreas of *A. meridianus* from the Hayle exposed to lead suggest that both copper and lead are present at the same sites within the cells of the hepatopancreas (Fig. 3*a–c*). It is apparent that both copper and lead compete for sites in the hepatopancreas of this tolerant isopod, as both chemical analysis (Fig. 4) and microanalysis confirm a relationship between the two metals. X-ray microanalysis further demonstrates that lead is present only in the 'cuprosomes' of exposed animals. It is suggested that lead is more readily bound than copper, which is released into the lumen of the hepatopancreas, probably as a result of apocrine secretion (Fig. 3*a*) in which the apical end of the cell is lost together with the granules[8], in response to an incoming dose of lead. Similar preferential binding of lead over copper has also been observed in earthworm chloragosomes (Ireland, personal communication).

The ability of copper-tolerant isopods from the Hayle to 'detoxify' lead by storing the metal in 'cuprosomes' at the expense of copper indicates that metal tolerance in invertebrates may not be as specific as had originally been supposed. Also, the mechanisms operating for particular metals, in this case lead and

0028-0836/78/0276—0388$01 00

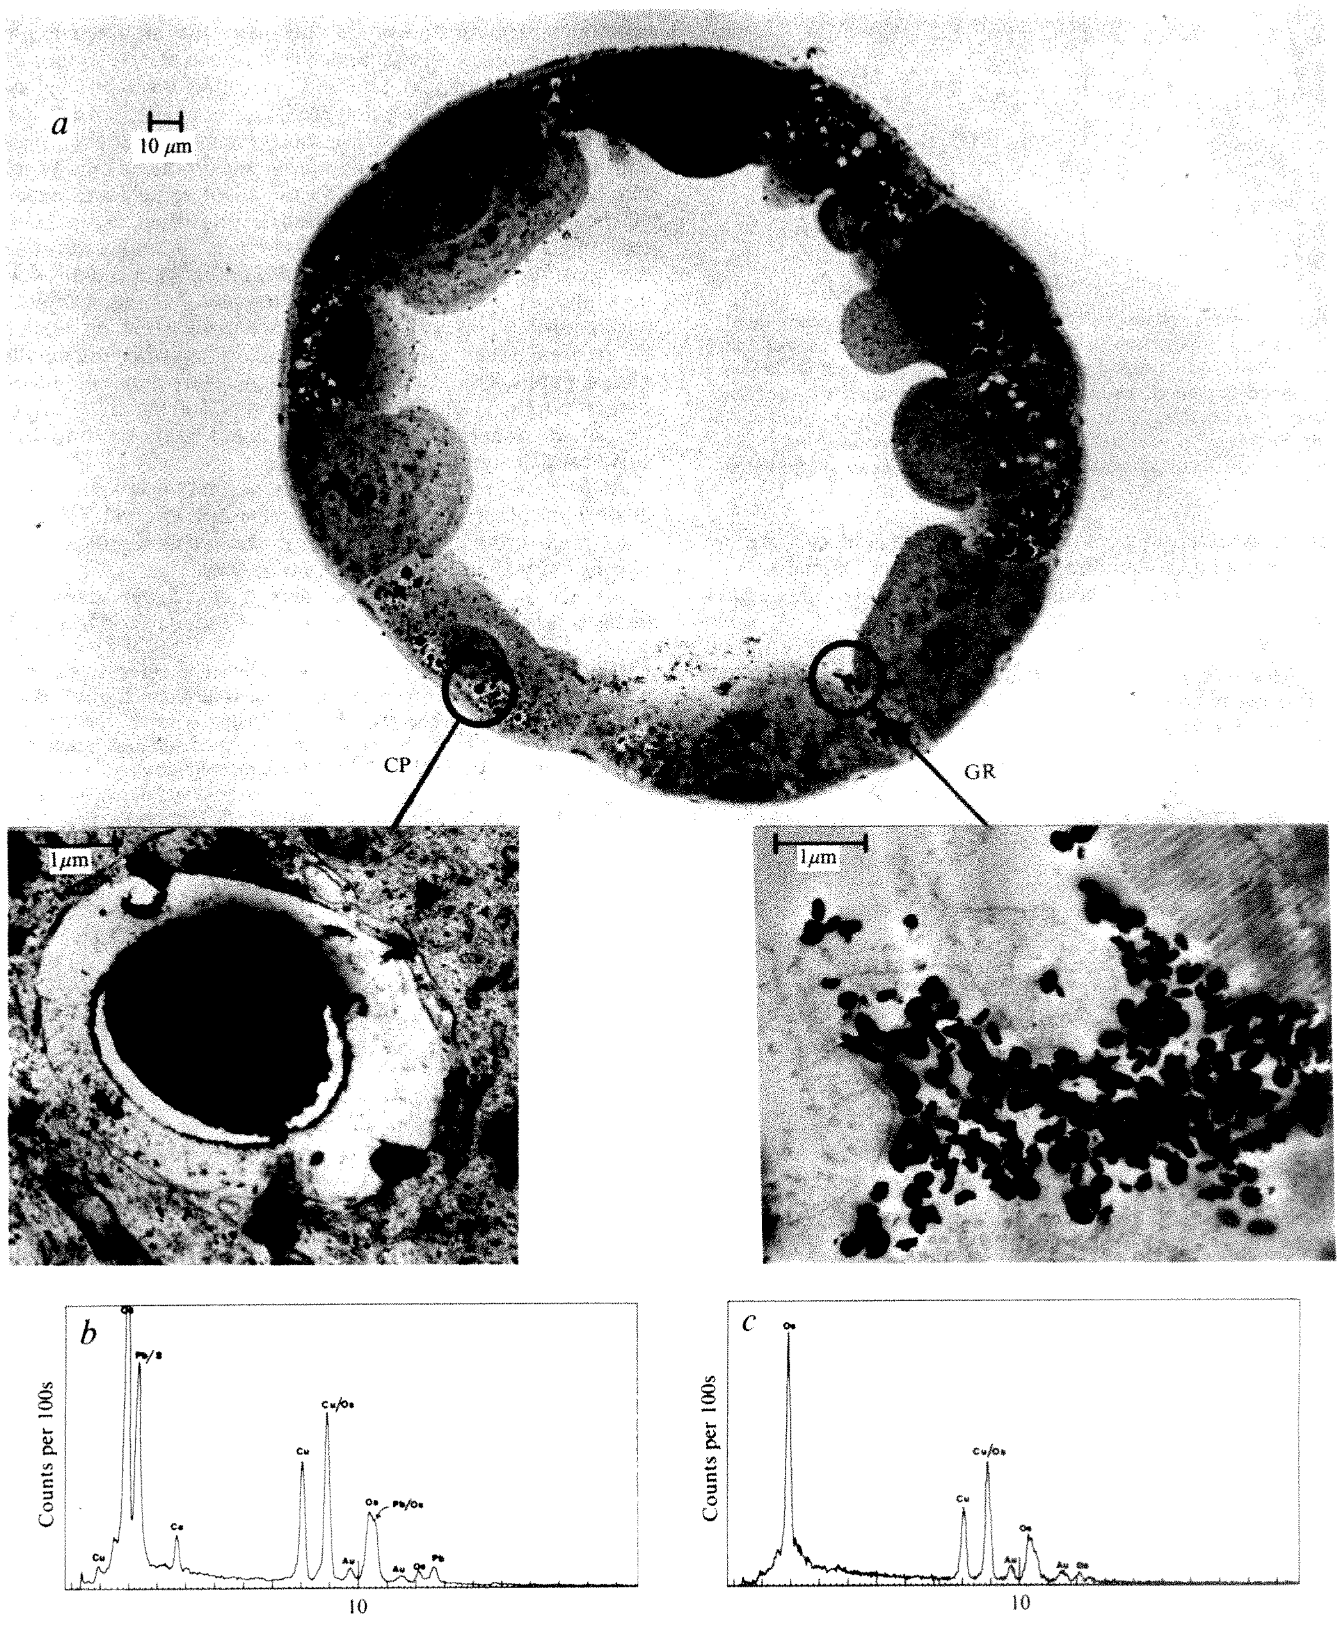

Fig. 3 Uptake of lead by isopods from the River Hayle exposed to 0.5 mg l^{-1} Pb for 10 d at 15 °C ± 1 °C. *a*, Photomicrograph showing 1-μm section of the hepatopancreas, stained with toluidine blue, of an exposed Hayle animal. Insets show electronmicrographs of densely staining 'cuprosomes' (CP) around the border of the cells and granular material (GR) being released into the lumen of the hepatopancreas. The hepatopancreatic caeca of lead-exposed animals were fixed in gluteraldehyde and osmium tetroxide, dehydrated and embedded in Araldite. 1-μm sections were cut and stained in toluidine blue and thin sections (600–1,000 Å) were then mounted on copper grids for ultrastructural analysis. The sections were viewed in an EM6-b (AEI Scientific Apparatus) electron microscope. *b*, The elemental spectrum of a cuprosome (CP) of a lead-exposed animal, showing peaks for Os (fixative), Au (grid) and constituents (Pb, Cu, Ca, S) of cuprosome. *c*, The elemental spectrum of granular material in the lumen of the hepatopancreas of a lead-exposed animal showing peaks for Os (fixative), Au (grid) and constituents of granular material (Cu). Hepatopancreatic caeca were fixed as above and sections (600–1,000 Å) mounted on gold grids for analysis by the electron microscope micro-analyser EMMA 4 (AEI Scientific Apparatus). Full vertical scale is 18,300 counts; in both cases the displayed spectrum takes into account the spectrum for the surrounding cytoplasm, which has been subtracted from the original.

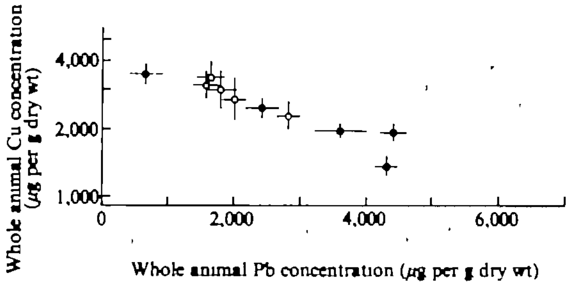

Fig. 4 Levels of copper plotted against levels of lead accumulated by whole animals from the Hayle during exposure to copper and lead alone and to mixed solutions of copper and lead. ●, Points obtained during exposure of animals to a constant Cu concentration and increasing Pb concentrations; ○, points obtained during exposure of animals to a constant Pb concentration and increasing Cu concentrations Each point is the mean of four batch samples; bars represent the s.e.m.

copper, in different populations of the same species are not necessarily similar, as indicated by the ability of Gannel animals to restrict the uptake of both copper and lead into the hepatopancreas.

I thank Dr T. Appleton for assistance with X-ray microanalysis and R. Hewitt for assistance in preparation of material for electron microscopy. The work was supported by the Natural Environment Research Council.

Transient tritanopia experiment in blue cone monochromacy

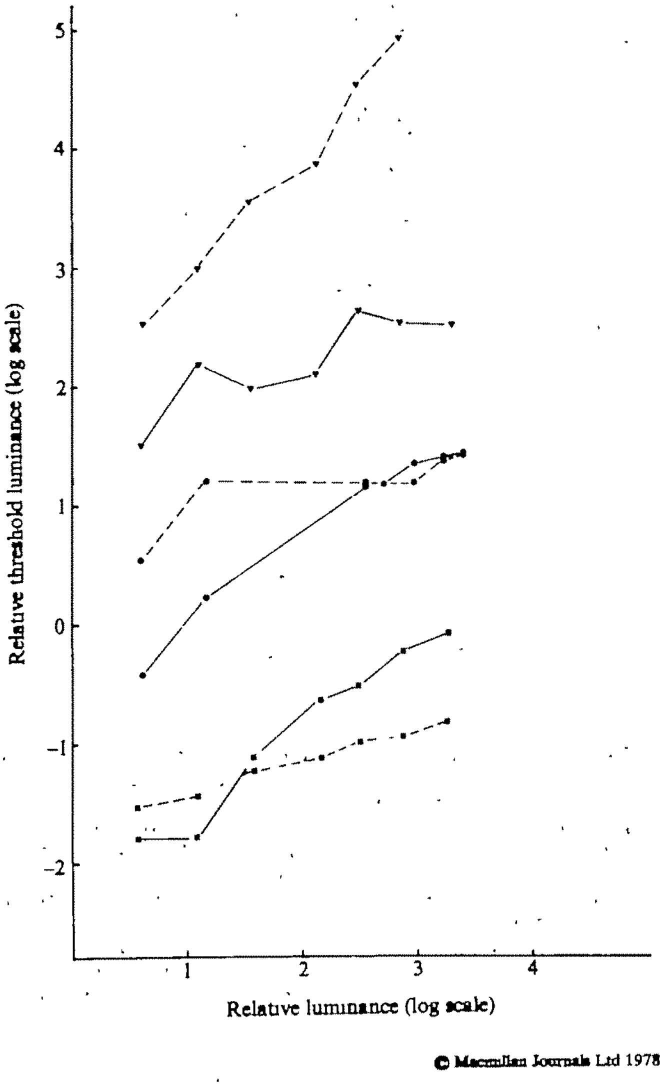
WHEN the eye has been adapted to a bright yellow light, a marked loss of sensitivity to short-wavelength stimuli may be recorded immediately after the extinction of the adapting field. This phenomenon, first described by Stiles[1], was termed transient tritanopia by Mollon and Polden[2]. They supposed that a recovering long-wavelength mechanism may inhibit or otherwise suppress the blue cone signal during early dark adaptation. Transient tritanopia was found in one protanope and, in a modified form, in one deuteranope. This indicates that each of the red or green mechanisms or both in combination may give rise to the inhibition effect. It is of particular interest in this connection to know if this kind of inhibition is present in persons without red or green cones. In blue cone monochromacy, a unique kind of colour vision anomaly, there are only blue cones and no functioning red or green cones. We report here the experimental results obtained with such a person where no suppression effect upon the blue mechanism could be demonstrated. The results are compared with those of a typical rod monochromat and a person with normal vision.

The blue cone monochromat (BTW), a 17-yr-old male, had visual acuity of 6/60 in each eye. He had pendular nystagmus and moderate photophobia. The presence of functioning blue cones was ascertained during the clinical examination and by spectral sensitivity studies[3]. By means of two modified Prado Universal projectors, a monochromatic circular test spot of 450 nm and 1° angular size was presented on a 30° yellow adapting field projected on a $BaSO_4$ screen. The viewing distance was 0.40 m. The test spot was presented about 1° above a fixation mark. The field of adaptation was produced by a Wratten 12 gelatine filter. Every 18 s the adapting field was extinguished for 3 s and a single test flash, lasting 30 ms, was presented 400 ms after the extinction of the field. Stimulus duration was controlled by electromechanical shutters. Maxwellian-view presentation was not preferred because of the subject's nystagmus. Preliminary experiments did not show significant differences either using artificial pupils or with maximally dilated pupils. The experiments were therefore performed with natural pupils. During the short period of 400 ms after extinction of the adapting field the pupil is not likely to show any significant change[4].

At photopic adaptation levels, the normal observer shows a distinct loss of threshold sensitivity in the dark interval. The blue cone monochromat subject, however, showed no significant loss of sensitivity at any level of adaptation (Fig. 1).

A slight increase of threshold sensitivity at lower adaptation levels is seen in the normal observer and is due to rod intrusion

Fig. 1 The transient tritanopia experiment in three kinds of observers: a normal trichromat (■), a blue cone monochromat (●) and a rod monochromat (▼). Ordinate, relative threshold luminance at which the blue test spot is detected; abscissa, relative luminance of adapting field. - - - -, log threshold luminance recorded on a steady yellow field. ——, log threshold luminance 400 ms after the adapting field has been turned off. Luminance is given relative to 1 cd m^{-2}. The curves for the blue cone monochromat and the rod monochromat have been displaced 2 and 4 log units respectively along the ordinate axis.



consequent to the parafoveal stimulation. This increase of sensitivity is more pronounced in the blue cone monochromat, probably because his nystagmus causes a greater participation of rod receptors.

As rod activity thus influences the response functions, it is of interest to study the results obtained in the same conditions in a rod monochromat, that is, a person without ordinary cones. The results of the rod monochromat are shown in Fig. 1 by the top curves. At low adaptation levels, the response pattern is similar to that of the blue cone monochromat, but it differs significantly at higher adaptation levels. The ratio between threshold values in the light and dark intervals increases with the luminance of the background light. At high luminances the threshold sensitivity regains more than 2 log units during the short period of 400 ms after extinction of the background light. This fast recovery rate is essentially different from the responses of the two other observers having both cones and rods in their retinas.

When acting without the influence of other receptors, the rod mechanism, thus has a very great ability of recovering after exposure to the yellow light. By the presence of blue cones this ability of fast recovering is completely lost, as the threshold values are now at the same level irrespective of the background light being on or off. When green and red cones are present, there is also a suppression of the blue mechanism giving further loss of threshold sensitivity in the dark interval. This, which is the transient tritanopia, is demonstrated by the normal observer.

The lack of transient tritanopia in the blue cone monochromat supports the theory of Mollon and Polden that this phenomenon in normal persons is an effect due to the inhibition of the blue cone mechanism by the other cones.

Mutagenic action of aromatic epoxy resins

EPOXY RESINS are used extensively for protective coatings and in paints and adhesives; the consumption of epoxy resins during 1973 was 190,000 metric tons, which is an almost twofold increase over a period of 10 years[1]. About 90% of the epoxy resins used are manufactured by condensation of two molecules of epichlorhydrin with one or more molecules of bisphenol A (2,2-bis (4-hydroxyphenyl)-propane). The mutagenic action of simple epoxides such as ethylenoxide and epichlorhydrin was first shown in fruit flies[2] and has subsequently been demonstrated in a wide range of organisms. Epoxy resins are diepoxides and bifunctional alkylating agents, and bifunctional alkylating epoxides are known to be mutagenic[3,4]. Mutagens are suspected of having a carcinogenic effect because of the relationship between carcinogenicity and mutagenicity[5] and most diepoxides are carcinogenic in mice and rats[6]. We report here that aromatic epoxy resins are mutagenic in *Salmonella typhimurium*, and may thus represent a cancer risk in man.

Table 1 Compounds tested by the *Salmonella*/microsomé mutagenicity test

			MW	*n*
Epikote	828	(E 828)	370	0
Epikote	1001	(E 1001)	950	1
Epikote	1004	(E 1004)	1,800	3
				
Epichlorhydrin		(ECH)		92.5

The Epikote resins were supplied by Shell Chemicals According to that firm, Epikote 828 is basically the diglycidylether of bisphenol A, as indicated by the formula, plus a small proportion of higher molecular weight material. The higher molecular weight resins contain some resin of lower molecular weight. Epichlorhydrin was from Fluka.

Three aromatic epoxy resins were tested by the plate incorporation assay with histidine-requiring mutants of *S. typhimurium*. The test was carried out as described by Ames *et al.*[7]. Epichlorhydrin (ECH) was included as positive control (see Table 1). The epoxy resins are all mutagenic in tester strain TA 100 (Fig. 1).

To ensure that mutagenic action was not due to interaction between the resins and dimethyl sulphoxide (DMSO), which is normally used as solvent in the plate incorporation assay, we also tested an aqueous emulsion made by ultrasonic emulsification of E 828. The aqueous emulsion was mutagenic to *S.typhimurium* TA 100, but to a lesser extent than in assays where DMSO was used as solvent.

E 828 was the most active compound of the resins tested, and both E 828 and E 1001 were more mutagenic than the positive control, ECH. The solubility of the resins decreases as the molecular weight increases. The resins were suspended in the agar medium in the amounts shown in Fig 1. However, as the resins were not in solution, the amounts given may not express the true doses.

Comparison of the first column of Table 2 with Fig. 1 shows that the mutagenic action of ECH in tester strain TA 1535 was about the same as that demonstrated with TA 100. In contrast, the mutagenic activity of the resins was very low compared with that observed using TA 100. This indicates that the mutagenic action of the resins is not caused solely by the possible content of unreacted ECH in the resins.

Assays were carried out to determine the mutagenic effect of epoxy resin metabolites. After addition to the plates of rat liver microsomes, prepared from rat liver activated with sodium phenobarbital and containing NADP, the mutagenic activity of the epoxy resins and ECH was reduced almost 10-fold in assays with TA 100.

When the same assays were carried out with TA 1535, E 828 was clearly activated by rat liver enzymes in the presence of NADP (compare the second and first columns in Table 2). In contrast, this resin was inactivated in assays where NADP was omitted (see third column in Table 2). The results obtained with E 1001 showed the same tendency.

As in the assays with TA 100, the mutagenic activity of ECH in assays with TA 1535 was reduced almost 10-fold by rat liver enzymes (see Table 2). This reduction in activity was independent of the presence of NADP. The inactivation of epoxy resins and ECH by microsomes without NADP was enzymatic, since the addition of heat-inactivated microsomes to the plates gave the same results as shown in the first column of Table 2.

0028-0836/78/0276—0391$01 00

It is known from studies of polyaromatic hydrocarbons and styrene oxide that the microsomal epoxide hydrase catalyses the hydration of epoxides to diols, and that the soluble fraction glutathione-*S*-epoxide transferase catalyses the conjugation of epoxides with glutathione[8]. These two enzymes are active in rat liver preparations without NADP. The resulting metabolites are considered to be non-mutagenic or less mutagenic than the epoxide[9,10].

The activation of the aromatic epoxy resins as found in TA 1535 is not caused by decomposition of the compounds and liberation of bisphenol A. Bisphenol A was tested for mutagenicity, both with and without the addition of liver microsomes and was not active in tester strains TA 1535 or TA 100.

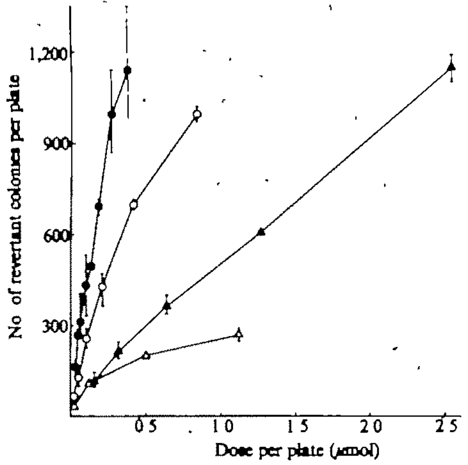

Fig. 1 Mutagenicity of aromatic epoxy resins and ECH for *S. typhimurium* TA 100 (revert by base-pair substitution). The epoxides were dissolved in 100 μl dimethyl sulphoxide (Merck, spectrometric grade). Bacteria and dissolved test agent were incorporated into the agar overlay. No S-9 mix was added. The number of spontaneous revertant colonies was estimated at 250. Each point is an average of numbers scored on three plates. The limits of the vertical lines indicate the lowest and highest values obtained with each dose. ●, E 828; ○, E 1001; △, E 1004; ▲, ECH (positive control)

Extensive studies of benzo(*a*) pyrene metabolites show that the combined epoxide hydrase–monooxygenase system leads to the formation of highly mutagenic diol-epoxide[11]. The monooxygenase system is dependent on NADP. Metabolites of this type might explain why NADP-dependent enzymes play a role in the formation of metabolites which are more mutagenic than the original epoxy resins to tester strain TA 1535, as shown in Table 2.

The demonstration of a mutagenic effect of aromatic epoxy resins in *S. typhimurium* indicates a genetic hazard, including a cancer risk, for humans exposed to these compounds. The fact that epoxy resins can be metabolised to mutagenic active compounds enhances the genetic risk from aromatic epoxy resins. Man is exposed to the resins during their manufacture and use either by skin contact with the compound or by inhalation of air contaminated with droplets or powder particles of epoxy resin. It has been demonstrated that topical aromatic epoxy resins (MW 350) are toxic to rats[12]. Therefore, it seems that the resins can penetrate the skin and be absorbed by animals.

Aromatic epoxy resins have been tested for carcinogenicity. After one skin exposure to 900 μM aromatic epoxy resin (MW 395), one skin tumour and three malignant lymphomas appeared in 50 mice[13]. In a study with only 40 mice, no tumours were found after skin painting with undiluted resin[14] but results are inadequate since none of the animals was alive after 24 months. In a study by Hine *et al.*[15], four malignant sarcoma tumours were produced at the site of injection after administration to 30 rats.

Table 2 Activity of aromatic epoxy resin metabolites ascertained by the *Salmonella* microsome mutagenicity test

Compound	Dose (μmol per plate)	−S-9 mix	+S-9 mix	+S-9 mix (−NADP)
E 828	0.54	ND	39	ND
	1.35	ND	109	ND
	5.40	58	521	ND
	13.5	79	996	20
	54.0	162	ND	14
E 1001	2.1	24	39	9
ECH	0.254	216	ND	ND
	0.635	474	ND	ND
	2.54	1,418	34	35
	6.35	ND	152	105
	25.4	ND	911	731

The figures represent the numbers of revertant colonies per plate produced by various doses of aromatic expoxy resins and epichlorhydrin (ECH) in tester strain TA 1535 (reverting by base-pair substitution). The spontaneous revertents (36) are subtracted. Each figure is an average of numbers scored on 3–10 plates in two independent assays. ND, not determined. The plate incorporation assay described by Ames *et al*[7]. was followed without modification. The assay was performed with and without the addition of rat liver microsome preparations. To some plates, preparations containing NADP were added, that is S-9 mix described by Ames *et al.*[7]. In other plates S-9 mix without NADP was used. 150 μl S-9 was added to each plate.

Since malignant tumours were demonstrated, and as the number of animals was small and the period of observation short in the above-mentioned studies, there is no basis for concluding, as did Hine *et al.* and others, that aromatic epoxy resins are safe from the point of view of carcinogenicity.

Owing to the long latent period for genetic damage and most cancers in humans[16], it is not possible to identify the genetic or cancerogenic hazards of aromatic epoxy resins by epidemiological studies in the immediate future, since consumption on any scale may not have taken place until the 1960s.

To prevent cancer and genetic damage in humans it is necessary to minimise the exposure to substances such as aromatic epoxy resins which have been shown to be mutagenic in bacteria, and thus must be considered as potential mutagens and carcinogens in human beings.

T cell origin of human macromolecular insoluble cold globulin

THYMUS-DERIVED (T) lymphocytes are a heterogeneous cell population in terms of their function and the surface antigens they express. In the mouse, a subpopulation of sensitised T cells is cytotoxic for allogeneic or modified syngeneic target cells by virtue of recognition of histocompatability antigens, that is, H-2K and H-2D (refs 1 and 2). These cytotoxic T lymphocytes express a specific antigen of the Ly antigen series, Ly-2,3 (refs 3 and 4). Another subpopulation of T cells mediate responses in the mixed lymphocyte reaction and the graft-versus-host reaction[4,5]. These cells recognise immune response associated antigen (Ia) and possess another antigen of the Ly series, Ly-1 (refs 4 and 5). In addition, separate classes of T cells mediate helper and suppressor regulatory effects on antibody response and also have distinctive Ly membrane markers[4,6,7]. Although membrane proteins such as immunoglobulin and B-cell antigens are specific to bone marrow-derived (B) lymphocytes in humans, there are few well characterised proteins that serve to distinguish human T cells[8-12]. We have recently identified a glycoprotein synthesised in mouse thymocytes and splenocytes[13,14]. This protein has been termed macromolecular insoluble cold globulin (MICG) to describe its major physicochemical properties. It has a molecular weight of 225,000, is insoluble in the cold in non-ionic detergents and has the electrophoretic mobility of a β globulin. MICG has also been shown to be the exclusive product of T lymphocytes[15]. This report describes the characterisation of a similar protein in human T cells.

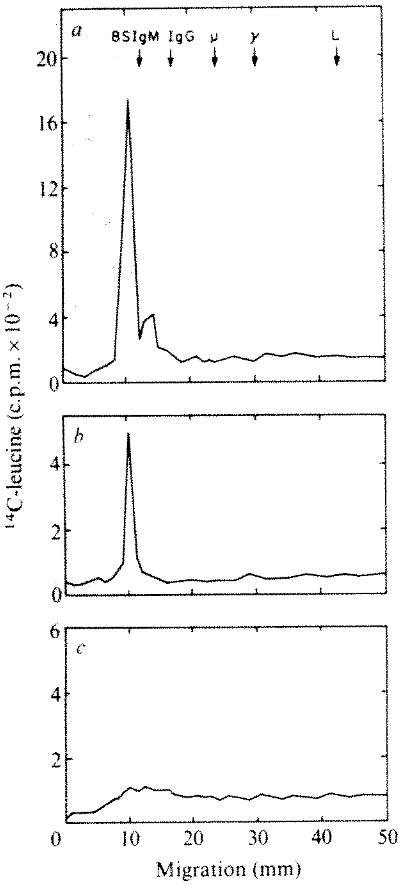

Fig. 1 Cold precipitation of ^{14}C-leucine labelled human MICG protein from lysates of: *a*, PBL (36×10^6); *b*, T cells (12×10^6); *c*, B cells (12×10^6). Precipitates were reduced and subjected to SDS-PAGE (5%). Top of gel is on the left side of figure. Arrows indicate the position of ^{14}C-leucine labelled markers (derived from mouse plasmacytoma cells of the appropriate class) which were electrophoresed on companion gels[13]. 8S IgM unreduced monomer IgM (MW 200,000); IgG, unreduced intact IgG; μ, IgM heavy chains; γ, IgG heavy chains; L, light chains.

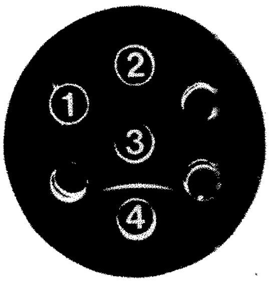

Fig. 2 Ouchterlony analysis (double immunodiffusion). Wells: 1, PBL lysate in 0.5% Triton X-100 and 2 M urea; 2, rabbit antiserum to human MICG; 3, rabbit antiserum to human cold insoluble globulin (given by M. Mosesson); 4, normal human plasma.

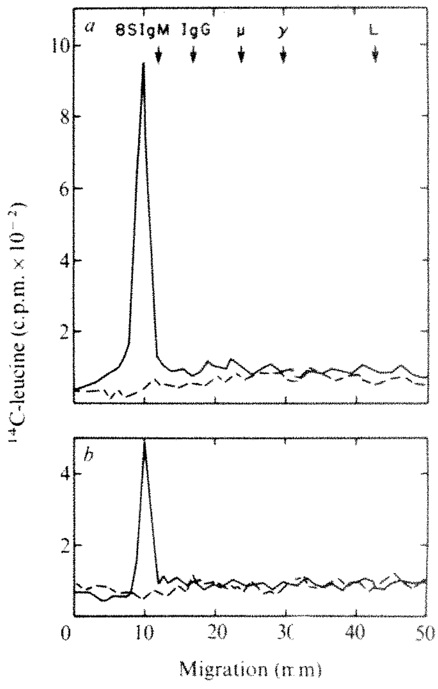
Peripheral blood lymphocytes (PBL) were separated from heparinised whole blood by Ficoll-Hypaque centrifugation (FHC)[16]. T lymphocytes were isolated from PBL by rosette formation with sheep red blood cells (SRBC) and sedimentation on FHC[17]. The lymphocytes from the SRBC pellet (after lysis of SRBC) were used as a source of T cells. They contained less than 2% surface immunoglobulin-positive cells and 97% of these cells formed rosettes with SRBC. B lymphocytes were isolated from the B cell-enriched fraction (unrosetted cells) at the Ficoll–medium interphase by application to Sephadex G-200 anti-human Fab columns[18,19]. Bound cells, eluted by competitive inhibition with human IgG, were 98% surface immunoglobulin-positive and less than 1% formed rosettes with SRBC. Surface immunoglobulin-positive cells were determined by fluorescence microscopy using rabbit anti-human light chain antiserum labelled with fluorescein isothiocyanate[20].

Fig. 3 Antiserum precipitation of radiolabelled lysates from PBL, T cells and B cells. Lymphocytes, labelled with ^{14}C-leucine, were lysed in isotonic buffer[13], *p*H 7.2 and 0.5% (v/v) with respect to desoxycholate, for 20 min at 4 °C. Lysates were immunoprecipitated using antiserum (250 μl) in antibody excess for 16 h at 4 °C. Samples were reduced and treated on SDS-PAGE (5%). *a*, PBL (75×10^6) precipitated with either anti-MICG antiserum (——) or normal rabbit serum (- - - -); *b*, T cells (40×10^6) (——) or B cells (40×10^6) (- - - -) precipitated with anti-MICG antiserum.



0028–0836/78/0276—0393$01.00

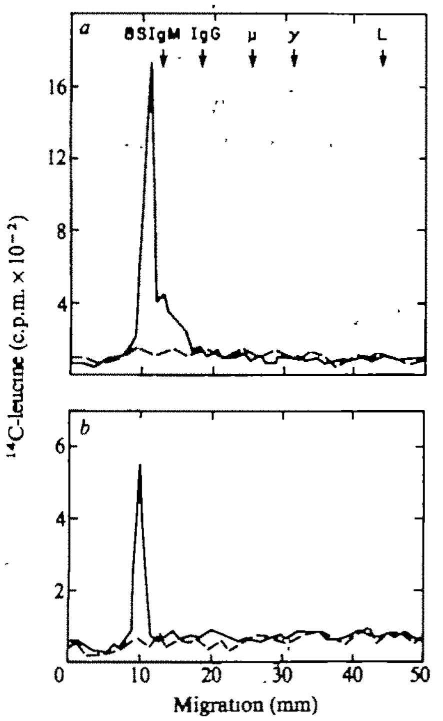


Fig. 4 Specificity of antihuman MICG antiserum. Radiolabelled (^{14}C-leucine) PBL lysates were precipitated and electrophoresed on 5% SDS gels after reduction: *a*, PBL (50×10^6) were lysed in NP-40 and cold precipitated (——) at 4 °C for 2 d and the supernatant reacted with anti-MICG antiserum (250 μl) in antibody excess (– – – –). *b*, Lysates from PBL (30×10^6), prepared as in Fig. 3, were reacted with either unadsorbed anti-MICG antiserum (——) or anti-MICG adsorbed with T cells (300×10^6 T cells per ml antiserum) for 1 h at 37 °C (– – – –).

Lymphocytes, radiolabelled with 10 μCi of ^{14}C-leucine, were lysed in Nonidet P-40 (NP-40) and the lysates cold precipitated for 2 d at 4 °C in detergent buffer[14]. The washed precipitates were dissolved in 2% SDS–8 M urea–phosphate buffer for 1 h at 37 °C, reduced with 0.5 M 2-mercaptoethanol and alkylated with 0.65 M iodoacetamide. The samples were then electrophoresed on 5% SDS–polyacrylamide gels, and the gels sliced and counted[14]. Cold precipitated PBL lysates demonstrated a major peak of radioactivity with a molecular weight of 225,000 (Fig. 1*a*), compared with appropriate standards[14]. Incubation of cell lysates for 2 d at 22 °C did not induce the precipitation of this macromolecule. Similar to mouse MICG, the 225,000 MW protein had the electrophoretic mobility of a *β* globulin.

To investigate the cell of origin of this protein, PBL were separated into T and B lymphocyte subpopulations and radiolabelled lysates analysed for cold insolubility. As shown in Fig. 1*b* and *c*, only isolated T cells were able to synthesise the cold precipitable macromolecule. There was no radioactivity cold precipitated from B lymphocytes.

The relationship between MICG and human serum proteins was analysed with antiserum to isolated MICG[14]. This antiserum did not react with isolated, radioiodinated proteins, including albumin, α_2 macroglobulin, transferrin, IgG, IgA or IgM, nor did it react with concentrated human plasma or serum in Ouchterlony analysis[14]. In contrast, antiserum to MICG showed a single precipitan band with PBL lysates (Fig. 2). Note also that a variety of monospecific antisera to human serum proteins did not react with PBL lysates in Ouchterlony analysis. These included antisera to α_2 macroglobulin, albumin, transferrin, IgM, IgA, IgG, IgD, IgE, fibrinogen, cold insoluble globulin and whole plasma (Fig. 2).

Monospecificity of this antiserum was also shown by direct precipitation of radiolabelled lysates derived from PBL, T cells and B cells. As MICG is insoluble in the cold in non-ionic detergents, it was necessary to lyse lymphocytes with a detergent in which MICG was soluble. When radiolabelled lymphocytes were lysed in Desoxycholate, the macromolecule remained in solution. After precipitation of these lysates with antiserum to MICG, a single peak of radioactivity was demonstrated on SDS gels for both PBL and T cell lysates (Fig. 3*a* and *b*). The molecular weight of this protein was 225,000, when compared with appropriate standards. In contrast, no radioactivity was precipitated from B cells with anti-MICG antiserum (Fig. 3*b*), nor did normal rabbit serum react with the radiolabelled lysates (Fig. 3*a*).

To determine whether the 225,000 cryoprotein visualised using SDS–polyacrylamide gel electrophoresis (PAGE) was similar to the protein precipitated by anti-MICG antiserum, radiolabelled PBL lysates were cold precipitated and the supernatant allowed to react with antiserum to MICG. Following cold precipitation there was no radioactivity precipitated from the supernatant with anti-MICG antiserum (Fig. 4*a*). The reverse of this experiment, whereby radiolabelled lysates were first precipitated with anti-MICG antiserum and the supernatant cold precipitated, also demonstrated antigenic similarity (not shown).

As a final proof of the specificity of this antiserum for T cells, the antiserum was adsorbed with T cells and reacted with radiolabelled PBL lysates. In these conditions, the antiserum was not reactive with the radiolabelled lysate (Fig. 4*b*). When the antiserum was adsorbed with B lymphocytes, there was no loss of activity against PBL.

The present experiments demonstrate a unique protein present in human T cells. It has similar chemical characteristics to mouse MICG and has been termed human T-MICG. Further studies are in progress to elucidate the biological function of this protein. Certainly, T-MICG serves to distinguish human T cells from B cells.

Mode of coupling between hormone receptors and adenylate cyclase elucidated by modulation of membrane fluidity

THE hormone- and neurotransmitter-dependent adenylate cyclases represent transmembrane regulatory systems in which the receptor unit faces the outside of the cell and the cyclase catalytic unit faces the inside. When the hormone or neurotransmitter binds to the receptor, the catalytic unit of the cyclase is activated and produces cyclic AMP at the inner surface of the membrane[1]. It has recently become clear that some hormone receptors are permanently coupled to adenylate cyclase whereas others are not. We demonstrate here that the effects of modulating membrane fluidity on the rate of adenlyate cyclase activation can be used to distinguish between the two modes of coupling.

Activation of adenylate cyclase requires the simultaneous binding of hormone to receptor and intracellular GTP to the guanyl nucleotide regulatory subunit[2]. Furthermore, in the case of the β-adrenergic receptor the hormone signal is terminated concomitantly with the hydrolysis of GTP to GDP and inorganic phosphate at the regulatory site[3]. Thus for the β-adrenergic receptor, and perhaps generally, the continued presence of both hormone and GTP is essential to maintain the steady-state level of active adenylate cyclase[2,3]. This mechanism may also account for the observation that non-hydrolysable GTP analogues induce a permanently active state of the cyclase in the presence of hormone. When the latter occupies the GTP regulatory site, the GTPase step is blocked and the enzyme remains in its inactivated state[2,4,5].

Recent evidence suggests two alternative modes of interaction between the receptor regulatory unit and the catalytic cyclase unit. Either the receptor and the enzyme are mobile and float in the membrane[6-10] (in this case the activation of the catalytic moiety takes place during the encounter between receptor and enzyme) or the receptor and the enzyme are permanently coupled to each other, as a typical soluble regulatory enzyme composed of regulatory and catalytic subunits such as aspartate transcarbanylase (in this case the subunit interactions are similar to those of classic regulatory proteins in solutions). The first mechanism is described in the following scheme:

$$\begin{array}{l} \mathrm{HR+E} \xrightarrow{k_1} \mathrm{(HRE)} \xrightarrow{k_2} \mathrm{HR+E'} \\ \quad \uparrow\!\downarrow K_\mathrm{H} \\ \mathrm{H+R} \end{array} \qquad (1)$$

where H is the hormone, E the enzyme, R the receptor, k_1 the bimolecular rate constant, E′ the activated enzyme, K_H the receptor–hormone dissociation constant and k_2 the first order activation constant. (HRE) indicates the transient ternary complex, the hormone–receptor–enzyme. If the ternary complex is short-lived ($k_2 \gg k_1$), the encounter between hormone-bound receptor and catalytic unit becomes rate limiting. Such a coupling mechanism has been termed 'collision coupling'. The second mechanism (permanent coupling) can be described by the following scheme:

$$\begin{array}{l} \mathrm{HRE} \xrightarrow{k} \mathrm{HRE'} \\ \quad \uparrow\!\downarrow K_\mathrm{H} \\ \mathrm{H+RE} \end{array} \qquad (2)$$

where RE is the receptor–enzyme complex, H the hormone, k, the first-order constant of activation and K_H the dissociation constant of hormone to receptor–enzyme complex.

In these two schemes we have eliminated the deactivation process of the active enzyme species. This is achieved in hormone-dependent adenylate cyclases when nonhydrolisable GTP analogues such as guanylylimidodiphosphate (GppNHp) replace GTP in the adenylate cyclase reaction[2,5]. Therefore, in the presence of hormone and GppNHp, the enzyme becomes permanently active and accumulates according to[9,10]:

$$B = A\{1-\exp(-k_\mathrm{obs}t)\} \qquad (3)$$

In the 'collision coupling' model (equation (1)), A = total concentration of catalytic units and B concentration of the units activated at time t. k_obs Is the pseudo first-order rate constant given by:

$$k_\mathrm{obs} = k_1[\mathrm{R_T}]\frac{[\mathrm{H}]}{K_\mathrm{H}+[\mathrm{H}]} \qquad (4)$$

where $[\mathrm{R_T}]$ is the total receptor concentration, k_1 the bimolecular rate constant and the term $[\mathrm{H}]/(K_\mathrm{H}+[\mathrm{H}])$ expresses the fraction of hormone-occupied receptors.

The maximal number of the activated catalytic units in that case is independent of receptor concentration, as every receptor can activate an unlimited number of catalytic units through the collision process. It is apparent from equation (4) that k_obs is directly proportional to the receptor concentration.

For equation (2), A in equation (3) is the total concentration of receptor–enzyme and B the concentration of the activated receptor–enzyme unit at time t. K_obs In this case is given only by:

$$k_\mathrm{obs} = \frac{k[\mathrm{H}]}{K_\mathrm{H}+[\mathrm{H}]} \qquad (5)$$

where k is the first-order rate constant of activation and the term $[\mathrm{H}]/(K_\mathrm{H}+[\mathrm{H}])$ is the fractional occupancy of the receptor by the hormone. At saturating hormone concentrations this term is equal to one.

We have recently shown[9,10] that the coupling of turkey erythrocyte adenylate cyclase to the β-adrenoceptor is 'collision coupling' whereas the adenosine receptor is permanently coupled to the enzyme in the same cell[11,12]. This was based on the observation that progessive destruction of the β-adrenergic receptor by a specific affinity label results in a proportional decrease in the rate constant of cyclase activation by the receptor, without reduction in the total number of catalytic units which can be activated. In contrast, progressive destruction of the adenosine receptor by a specific affinity label results in a proportional decrease in the number of catalytic units which can be activated without a change in the rate constant of activation[12]. As the collision coupling mechanism, in contrast to the precoupled mechanism, necessitates a relative movement of the receptor with respect to the catalytic units in the membrane matrix, a different dependence of enzyme activation by the hormone through membrane fluidity is expected for epinephrine compared with adenosine.

To test this hypothesis we modified the fluidity of turkey erythrocyte membranes and measured the kinetics of enzyme activation by epinephrine and by adenosine. Turkey erythrocyte membranes were fluidised progressively by the insertion of *cis*-vaccenic acid which is one of the most efficient fluidising agents[13]. The apparent membrane microviscosity was measured using fluorescence polarisation[14], using 1,6-diphenyl(1,3,5)hexatriene (DPH) as the fluorescence probe. In parallel, we measured the time course of adenylate cyclase activation to its permanently active state, by either *l*-adrenaline or adenosine, in the presence of saturating concentrations of GppNHp. The first-order rate constants for the first-order process of adenylate cyclase activation by the two hormones were derived from equation (3) according to the procedure described elsewhere[9,10].

Figure 1 shows that the rate constant of the epinephrine-dependent activation increases linearly with membrane fluidity, whereas the rate constant of the adenosine-dependent activation is independent of membrane fluidity. This supports the kinetic experiments described above. Furthermore, the linear depencence of k_obs on $1/\eta$ in the case of the adrenaline-dependent activation, strongly suggests that the interaction between receptor and enzyme is diffusion controlled.

The inverse relationship between the rate of a diffusion-controlled bimolecular reaction and the viscosity of the medium is well established[15,16]. When the bimolecular reaction occurs in two dimensions the relationship is[17]:

$$k_1 = \frac{k_\mathrm{obs}}{[\mathrm{R_T}]} = \frac{N_\mathrm{A}\cdot 4\pi \cdot D_\mathrm{R,E}}{\ln\left[\left(\frac{\pi}{4}[\mathrm{R_T}]N_\mathrm{A}\right)^{1/2}\cdot\frac{1}{a}\right]} \qquad (6)$$

where k_1 is the bimolecular rate constant (equation (1)), k_obs the measured pseudo first-order rate of enzyme activation (equations (3) and (4)), $D_\mathrm{R,E}$ relative diffusion coefficient, $[\mathrm{R_T}]$ total receptor concentration, N_A Avogadro's number and a the

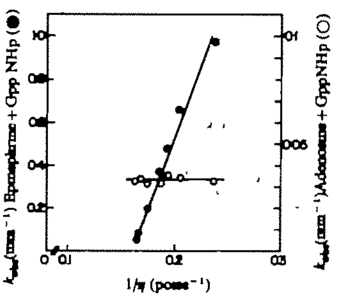

Fig. 1 The dependence of the rate constant of adenylate cyclase activation by *l*-adrenaline and by adenosine on membrane fluidity. Adenosine- and *l*-adrenaline-induced first-order processes of adenylate cyclase activation were measured as a function of increasing membrane fluidity. The kinetics of enzyme activation were determined and analysed as described in the text, using equation (3) to fit the hormone-induced activation curves. The fluidity of the membrane was increased progressively by treating the membrane with *cis*-vaccenic acid as described earlier[13] The fluidity of the membranes was measured by fluorescence polarisation using DPH as a fluorescence probe[14] (●), Dependence of k_{obs} for adrenaline activation on membrane fluidity; (○), dependence of k_{obs} for adenosine activation on membrane fluidity.

length of receptor to enzyme interaction domain. As the diffusion coefficient is inversely proportional the viscosity of the medium (Stokes'–Einstein relation) one can rewrite equation (6) as:

$$k_{obs} = \frac{N_A \cdot 4\pi[R_T]}{\ln\left[\left(\frac{\pi}{4}[R_T]N_A\right)^{1/2} \cdot \frac{1}{a}\right]} \times \frac{C}{\eta} \qquad (7)$$

where C is a constant and η the viscosity of the medium. From the slope of the plot of k_{obs} against $1/\eta$ the value of C can be calculated. Knowing η one can calculate the value of $D_{R,E}$.

Using the relationship between the bimolecular rate constant k_1 and the viscosity of the medium in a diffusion-controlled reaction in two dimensional space[17], one can calculate that the diffusion coefficient describing the relative motion of the receptor and the enzyme is in the range of 4.0×10^{-11} to 9×10^{-10} cm^2 s^{-1} at 25 °C. The value of k_1 can be obtained from k_{obs} ($k_1 \sim 1 \times 10^{13}$ min^{-1} (mol cm^{-2})$^{-1}$ (equation (4)) as $[R_T]$ is known for turkey erythrocytes[18,19]. This range of values for the diffusion coefficient is typical for mobile membrane receptors[20,21]. These values range from 2×10^{-11} to 4×10^{-9} cm^2 s^{-1}. The independence of the adenosine-induced rate of enzyme activation on membrane fluidity (Fig. 1) confirms previous biochemical studies[11,12] which showed that this receptor is permanently coupled to the cyclase.

The validity of the fluorescence depolarisation technique as a measure for membrane viscosity has been questioned[22]. It seems that even if the method does not yield the absolute value of the membrane viscosity these values are directly proportional to the viscosity. The fact that the data presented in this letter confirms the biochemical studies supports the view that the fluorescence polarisation technique is a powerful tool for measuring membrane viscosity. Furthermore, viscosity data which are derived from the rotation of small lipid-soluble molecules in the plane of the membrane approximate viscosity measured in other ways, for example by following diffusion of membrane proteins[23].

Membrane fluidity also affects the catalytic unit directly, as the maximal activity of the enzyme increases as a function of membrane fluidity. From Fig. 2 it is apparent that the adenosine-dependent activity, the adrenaline-dependent activity and the NaF-stimulated activity increase as a function of membrane fluidity in a similar way. Similar effects of membrane viscosity on the adenylate cyclase activity were recently reported[24,25]. The specific activity of other membrane bound systems, such as Ca^{2+}-ATPase[26], (Na^+, K^+)ATPase[27] and the β-galactoside transport system[28] were also found to depend on the membrane fluidity.

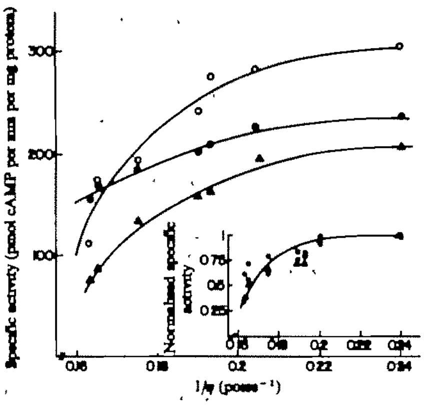

Fig. 2 The dependence of adenylate cyclase specific activity on membrane fluidity. The specific activity of adenylate cyclase as a function of membrane fluidity was measured in the presence of either 0.10 mM *l*-adrenaline plus 0.1 mM GppNHp (○), 0.1 mM adenosine plus 1.0×10^{-4} GppNHp (▲), or in the presence of 10 mM NaF (●). The assay mixture also contained 50 mM Tris-HCl, 6 mM $MgCl_2$, and 1 mM EDTA, pH 7.4, as described earlier[29]. Inset: The maximal specific activity for each mode of activation was taken as 1.0 and the relative increase in specific activity as a function of membrane fluidity was plotted. In this way one can compare the dependence of the three modes of activation with each other.

The dependence of the rate of adenylate cyclase activation by a hormone receptor on membrane fluidity can be adopted as a general diagnostic test for investigating coupling between a hormone receptor and adenylate cyclase. This approach can be extended to other membrane processes which involve the interaction between a receptor and a catalytic moiety, other than cyclase, such as an ionophore.

Monoclonal antibody to a human histocompatibility alloantigen, HLA-A2

ANTIGENS of the HLA-A, -B, -C and -DR series have been defined mainly using sera from multiparous women[1], which generally are comparatively weak, serologically complex and available in only limited quantities. Furthermore, large screening programmes are required to find usable sera, especially for rare specificities. Although antisera to HLA determinants can be produced in high titres by immunising animals of various species with purified HLA-A, -B, -C, -D antigens[2–5], they usually require extensive absorption to reveal polymorphic specificity and so have not so far been used as routine tissue-typing reagents. The development of techniques for producing hybrid cell lines secreting monoclonal antibodies of defined specificity[6,7], provides a way of circumventing the problems of generating human polymorphic antisera by heteroimmunisation and has already been used to produce a monoclonal antibody against the human blood group A determinant[8]. Here we describe the production of a cell line secreting an anti-HLA-A2 antibody.

Female BALB/c mice were immunised subcutaneously with 20 µg of purified papain-solubilised HLA-A2 antigen[9] in complete Freund's adjuvant. After 1 month an equivalent boost in incomplete Freund's adjuvent was given and 2 weeks later the mice bled and their sera tested for anti-HLA-A, -B, -C antibodies. Serum titres of between 1 in 1,000 and 1 in 5,000 as measured by an indirect binding assay[10] on human B-cell lines expressing HLA-A, -B, -C antigens were observed. The titres against the B-cell line Daudi, which does not express HLA-A, -B, -C or the associated β_2 microglobulin (β_2m) antigens[11] were less than 50 and not significantly different from that obtained with pre-immune serum. No specificity for HLA-A2 could be detected by this method. The three mice with the highest serum titres were boosted intravenously with 10 µg of HLA-A2 antigen in saline, killed 5 days later, their spleens removed and the spleen cells fused with the mouse myeloma cell line P3-NSL/1-Ag4-1 (refs 6, 7, 12). After fusion the cells were divided between 192 two-ml culture wells. Visible colonies of hybrid cells were observed in all wells after 2 weeks and the culture supernatants were then tested for binding activity against an HLA-A2 positive B-cell line (Bri 8). Positive activity was seen in 109/192 supernatants, and the cultures from 39 that gave greater than 6 times the background were grown and their supernatants tested against Bri 8 and Daudi cell lines. This distinguished anti-HLA-A, -B, -C or β_2m antibodies from those directed against other cell surface components. Of the 39 cultures 38 showed no reaction with Daudi cells, thus indicating the high specificity of this procedure for generating antibodies to HLA-A, -B, -C or β_2m antigens. On continued growth, 14 cultures retained strong activity and were selected for further study. The binding activity of all 14 supernatants was fully inhibited by pre-incubation with purified HLA-A2 antigen, but only one of them could be inhibited by pure β_2m. Thus, the majority of the antibodies produced show specificity for the HLA-A, -B, -C chain, in contrast to one report suggesting a predominance of anti β_2m antibodies following immunisation with whole cells[13].

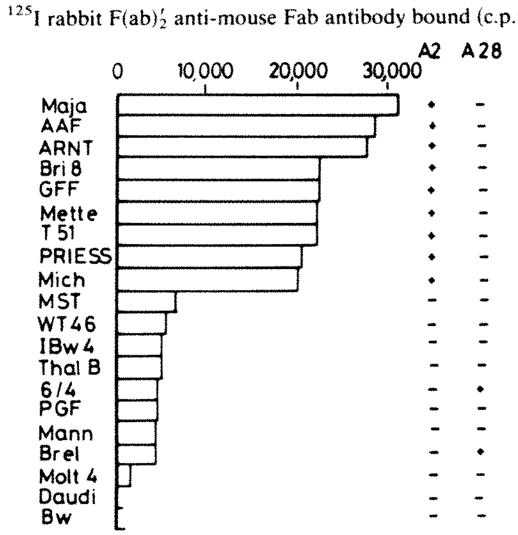

Fig. 1 Specificity of PA2.1 antibody for cell lines expressing HLA-A2 as measured by indirect trace binding assay. 10^6 cells were incubated with 50 µl of PA2.1 culture supernatant for 1 h at 4 °C, washed three times and then incubated with ^{125}I rabbit F(ab)$'_2$ anti-mouse Fab antibody, 300,000 c.p.m. for 1 h at 4 °C. The cells were washed four times and then counted for radioactivity. BW is a mouse thymoma cell line, Molt 4 a human T-cell line, all others are human B-cell lines[8].

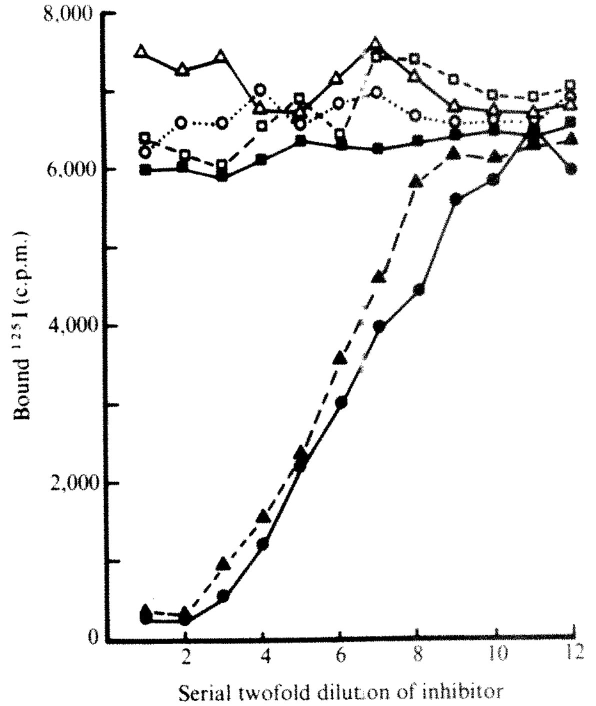

Fig. 2 Inhibition of PA2.1 antibody by purified papain-solubilised HLA-A, -B antigens with different antigenic specificity. HLA-A, -B antigen preparations (200 µg ml^{-1}) were serially diluted and 50 µl preincubated with 5 µl of PA2.1 supernatant for 1 h at 20 °C. Residual PA2.1 binding activity was then measured as for Fig. 1 with Bri 8 as the target cell (see refs 9 and 21). ●, HLA-A2 from J. Y. cells (homozygous *A2, B7*); ▲, HLA-A2 from 231 cells (homozygous *A2, B27*); □, HLA-A28 from L.B. cells (homozygous *A28, B40*); △, HLA-B40 from LB cells, ○, a mixture of HLA-A3, 25, B12, 27 from IM-1 cells (A3, 25, B12, 27); ■, a mixture of HLA-B7, 12 from RPMI 4265 cells (A2; B7, 12).

Of the 14 supernatants 10 reacted equally with all the cells from a panel of lines expressing a range of HLA-A, -B, -C antigenic specificities and so probably recognise antigenic determinants common to all HLA-A, -B, -C antigens comparable to a monoclonal antibody (W6/32) which has previously been described[18]. Polymorphic reaction patterns[4] were observed in 4 supernatants. PA2.1 reacted only with cells typed as HLA-A2 and did not react with cells expressing the highly cross-reactive HLA-A28 antigen[14] (Fig. 1).

Supernatants PA2.2, PA2.3 and PA2.4 reacted with some HLA-A2-negative cells as well as all HLA-A2-positive cells. These antibodies probably recognise cross-reacting antigenic determinants which HLA-A2 shares with some other HLA-A, -B, -C antigens. Their detailed specificity is being analysed, but

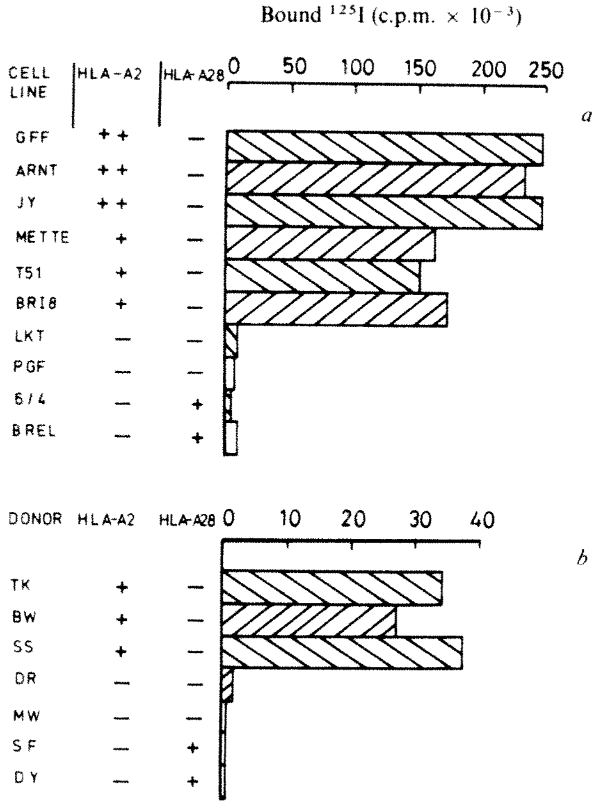

Fig. 3 Quantitation of HLA-A2 relative to total HLA-A, B, -C antigens on (*a*), B cell lines and (*b*), peripheral blood lymphocytes. The indirect binding of PA2.1 and W6/32 antibodies under saturating conditions of 1st antibody ($20\ \mu g\ ml^{-1}$) and 2nd antibody ($40\ \mu g\ ml^{-1}$) was measured on 5×10^5 cells in (*a*) and 2×10^6 cells in (*b*). The experimental procedure was as for Fig. 1 with an input of 3×10^6 counts per minute. To compare different cells within each group, the values plotted for the PA2.1 antibody binding have been normalised to a constant amount of radioactivity (representing total amount of HLA-A, -B, -C antigens) bound by the W6/32 antibody. This was the mean amount of radioactivity bound by the W6/32 antibody for all cells within a group and was 5×10^5 c.p.m. for B cell lines and 2.5×10^5 c.p.m. for peripheral blood lymphocytes. Cells are indicated as typed homozygous (++: based on family studies), heterozygous (+) and negative (−) for HLA-A2 and HLA-A28 by human alloantisera.

preliminary inhibition experiments with purified HLA-A, -B, -C antigens of different specificity indicate that supernatant PA2.2 probably reacts with a group including most HLA-A locus antigens.

Culture PA2.1 was cloned in soft agar[15] and one (PA2.1) of a number of colonies all with similar positive activity was arbitrarily selected for further study. The immunoglobulin secreted by PA2.1 was biosynthetically labelled with ^{14}C-lysine. Analysis by SDS-polyacrylamide gel electrophoresis, with other well characterised monoclonal antibodies as standards[16] showed that the PA2.1 antibody was an IgG molecule. It was not cytotoxic in complement-dependent antibody mediated cell lysis.

The specificity of the PA2.1 antibody for HLA-A2 was confirmed by inhibition with a variety of pure papain-solubilised HLA-A, -B, -C antigens (Fig. 2). Two preparations of HLA-A2 from different cell lines completely inhibited the PA2.1 antibody with similar specific activity, whereas four preparations representing eight other HLA-A, -B, -C antigenic specificities completely failed to inhibit. In particular, the PA2.1 antibody was not inhibited by the HLA-A28 preparation. It is unlikely that this was due to denaturation and loss of antigenic acitivity in the non-HLA-A2 antigen preparations, as all six fully inhibited the W6/32 monoclonal antibody, which recognises a determinant common to all HLA-A, -B, -C antigens that is dependent on the association of the HLA-A, -B, -C chain with β_2m and is easily inactivated by denaturation (data not shown).

HLA typing of B-cell lines often reveals patterns of serum cross reactions not usually observed with peripheral blood lymphocytes[17]. However, when PA2.1 antibody was tested by indirect binding against peripheral blood lymphocytes from a panel of 20 HLA-typed individuals it maintained its specificity for HLA-A2. Eight HLA-A2-positive individuals reacted strongly while 12 HLA-A2-negative individuals, including three who were HLA-A28 did not react (Fig. 3*b*). The same panel of peripheral lymphocytes was analysed in the fluorescence activated cell sorter after incubation with PA2.1 antibody and fluorescent labelled rabbit $F(ab)'_2$ anti mouse Fab antibody, using W3/25 monoclonal antibody with specificity for rat lymphocytes as control[18]. There was again complete concordance with HLA-A2, confirming the specificity of PA2.1 antibody for HLA-A2 and showing its potential use for cell separation. When the indirect binding assay is used with saturating amounts of antibody it is possible to quantitate the numbers of antigenic sites per cell[10]. By comparing the binding of PA2.1 and W6/32 antibodies, the proportion of the total HLA-A, -B, -C antigen which is HLA-A2 can also be estimated. As shown in Fig. 3*a*, cell lines homozygous and heterozygous for HLA-A2 could readily be distinguished. On this basis HLA-A2 accounted for 40–50% of the total HLA-A, -B, -C in homozygous cells and 30–35% of the total in heterozygous cells. Peripheral lymphocytes (Fig. 3*b*) had, per cell, about one eighth of the amount of HLA-A, -B, -C antigens found on B-cell lines as measured by the W6/32 antibody, although within each cell type the expression of HLA-A, -B, -C antigens varied by a factor of about two. In contrast to the B-cell lines, HLA-A2 accounts for only 12–15% of the total HLA-A, -B, -C expressed as W6/32 reactivity on the peripheral lymphocytes of individuals heterozygous for HLA-A2. This difference in apparent relative expression of HLA-A2 between EBV-transformed B-cell lines and a predominantly T-cell population of normal lymphocytes is being investigated further.

Xenogeneic immunisation between distantly related species, such as mouse and man, does not, in general, readily lead to the production of allospecific antibodies, although recently Lampson *et al.*[19] have produced limited quantities of anti-HLA-A2 antibodies using a mouse spleen cell culture system. We have shown, however, that it is possible by immunisation of mice with pure HLA antigen preparations to produce stable hybrid cell lines secreting mouse monoclonal antibodies directed at human polymorphic histocompatibility antigenic determinants. In addition to providing tissue typing reagents, these antibodies will be invaluable for the purification, separation and immunochemical analysis of HLA-A, -B, -C, -D molecules. We are, for example, now using the PA2.1 antibody to determine the antigenic structure of HLA-A2 and compare it with HLA-A28. Serological analysis of cross-reacting monoclonal antibodies such as PA2.2 may clarify the antigenic relationships between various HLA alleles and provide information on the evolution of this complex genetic system[20].

We thank Harry Orr and Jack Strominger for HLA antigen preparations, Alan Williams for the W3/25 and rabbit $F(ab)'_2$ antimouse Fab antibodies and Don Mason for cell sorter analyses. P. P. was supported by a Junior Fellowship from the Society of Fellows, Harvard University. We thank Colin Barnstable for many helpful discussions and Barbara Gunn and Beryl Winearls for their advice and technical help, and the MRC for support.

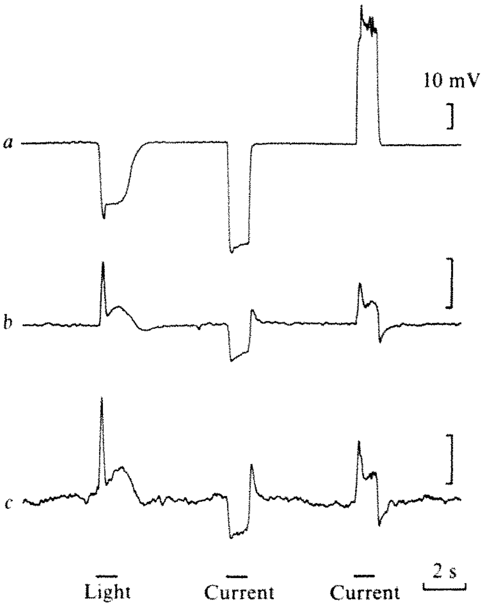
Effect of polarisation of horizontal cells on the on-centre bipolar cell of carp retina

THERE are two types of bipolar cell in the vertebrate retina, the on-centre and the off-centre cells[1,2]. The on-centre bipolar cells respond with depolarisation to the light spot in the centre of the receptive field and with hyperpolarisation to surround illumination. It is generally assumed that the effect of surround illumination is mediated by horizontal cells, as negative feedback from horizontal cells to photoreceptors has been demonstrated in the turtle retina[3]. Here we have attempted to clarify the role of horizontal cells in surround antagonism by hyperpolarising horizontal cells by applying extrinsic current in the retina of the carp, *Cyprinus carpio*. The response of the bipolar cells was similar to that elicited by surround illumination. However, the ionic mechanisms differed depending on the morphological type[4] of horizontal cell. An analysis of these mechanisms has led us to conclude that the external horizontal cells receiving inputs exclusively from cones modify the cone–bipolar transmission and the intermediate horizontal cells receiving inputs exclusively from rods modify the rod–bipolar transmission.

Fig. 1 Effect of polarisation of an intermediate horizontal cell on a bipolar cell. *a*, Potential changes of the intermediate horizontal cell; *b*, responses of the bipolar cell recorded simultaneously with *a*; *c*, responses of the same bipolar cell during hyperpolarisation of its membrane by steady current of 2.3 nA. In each trace the response to diffuse white light was tested first (left), then the horizontal cell was polarised in the dark to both hyperpolarising (middle) and depolarising (right) directions by extrinsic current through one barrel of a double-barrelled electrode. Timing of light and current stimuli is indicated below. The current used to polarise the horizontal cell was 10 nA. The coupling resistance of the double-barrelled electrode was 0.9 MΩ when measured in Ringer solution. The voltage drop across the coupling resistance was not compensated in these experiments. Calibration of 10 mV is shown at the end of each trace.



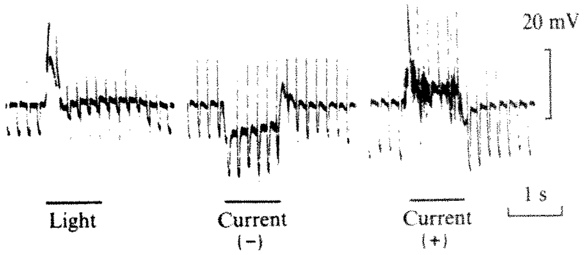


Fig. 2 Bridge records of bipolar cell responses to light (left) and to hyperpolarisation (middle) and depolarisation (right) of an intermediate horizontal cell by extrinsic current. Negative current pulses of 2.4 nA and of 50 ms duration were applied into the bipolar cell at a frequency of 5 pulses s^{-1} through the bridge circuit. The bridge was adjusted so that the decrease in the membrane resistance was indicated by a decrease in the height of pulses deflecting downward. The 20-mV change in the pulse height corresponds to 8.3-MΩ change in the membrane resistance. The response to light is accompanied by a resistance decrease. The hyperpolarising response to polarisation of the horizontal cell is accompanied by an increase and the depolarising response by a decrease in the membrane resistance.

Cajal[4] has described three morphologically different types of horizontal cell in the teleost fish retina; external, intermediate and internal. Both morphological and physiological studies have shown that external horizontal cells receive inputs exclusively from cones and intermediate horizontal cells exclusively from rods[2,5,6]. Recent studies further revealed two sublayers of external horizontal cells[7,8]. The cells in the distal layer are not colour-coded and give the response known as the L-type. Those in the second layer are colour-coded and give the response known as the C-type. The internal horizontal cells of Cajal are now considered as the processes of external horizontal cells[9]. These different types of horizontal cells were polarised in the present experiments by extrinsic current and its effect on bipolar cells was studied. The bipolar cells studied in these experiments were on-centre cells, because they were most frequently recorded and their responses were relatively stable. The bipolar cells recorded were identified by staining with Procion yellow as the large bipolar cells of Cajal which are known to have connections with both rods and cones[5,10].

Single- and double-barrelled microelectrodes, which could be advanced independently, were set almost parallel with their tip distance within 50 μm on the horizontal plane and were inserted into the isolated inverted retina vertically from above. When the responses of a bipolar and a horizontal cell were recorded, by single- and double-barrelled electrodes respectively, their cell types were identified by the response to diffuse white light of about 0.4 lm cm^{-2} and by changing patterns and wavelengths of the light stimulus if necessary. After confirmation of the response types, an extrinsic current of the order of 10 nA was passed through one barrel of the double-barrelled electrode in the absence of light but at the same timing as the light stimulus. In order to examine the ionic mechanisms of bipolar cell responses elicited by polarisation of horizontal cells, the membrane potential of bipolar cells was also changed by a steady polarising current or a train of current pulses of the order of 2 nA through a bridge circuit built in a preamplifier (WPI M701R). The steady current was used to estimate the reversal potential and the pulse current to measure the membrane resistance changes.

An example of simultaneous recordings from an intermediate horizontal cell (*a*) and an on-centre bipolar cell (*b*) is shown in

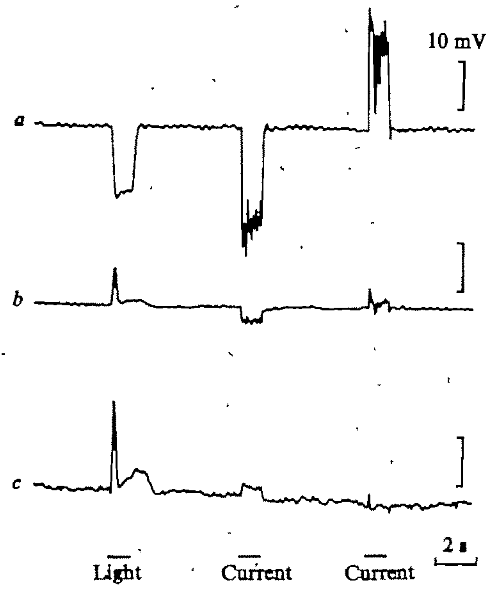
0028-0836/78/0276—0399$01.00

Fig. 1. The response of intermediate horizontal cells can be easily distinguished from that of external horizontal cells by its time course. The hyperpolarisation of intermediate horizontal cells by current elicited a hyperpolarising response in the on-centre cell and the depolarisation a depolarising response. When the bipolar cell was hyperpolarised by a steady extrinsic current, both hyperpolarising and depolarising responses elicited by the horizontal cell polarisation were augmented (*c*). The depolarisation of the bipolar cell resulted in a decrease in the response amplitude. The measurement of the membrane resistance changes revealed that the hyperpolarising response was accompanied by an increase and the depolarising response by a decrease in the membrane resistance (Fig. 2). It is inferred from these results that the effect of polarisation of intermediate horizontal cells is mediated by ionic channels such as sodium channels which have a positive reversal potential. These channels are made more permeable by depolarisation and less permeable by hyperpolarisation of intermediate horizontal cells.

An example of simultaneous recordings from an L-type external horizontal cell (*a*) and an on-centre bipolar cell (*b*) is shown in Fig. 3. The hyperpolarisation of external horizontal cells also elicited a hyperpolarising response in the on-centre cells and the depolarisation a depolarising response. These responses were made smaller or inverted by hyperpolarisation of the bipolar cell membrane by steady extrinsic current (*c*). They were augmented by depolarisation of the bipolar cell. The measurement of the membrane resistance changes revealed that the hyperpolarising response was accompanied by a decrease and the depolarising response by an increase in the membrane resistance (Fig. 4). It seems therefore that the effect of polarisation of external horizontal cells is mediated by ionic channels which have a more negative reversal potential than the membrane potential in the dark like potassium and/or chloride channels, commonly observed in the inhibitory synapses. These channels are made more permeable by hyperpolarisation and less permeable by depolarisation of the external horizontal cells.

Studies on the synaptic transmission from photoreceptors to on-centre bipolar cells indicate that rod signals are mediated by a permeability increase of subsynaptic sodium channels in the light and cone signals by a permeability decrease of subsynaptic potassium and/or chloride channels[11]. Our results are consistent with these data if we assume that intermediate horizontal cells not only receive exclusive inputs from rods and selectively affect the rod–bipolar transmission in a way expected from the feedback hypothesis, but the external horizontal cells receive exclusive inputs from cones and selectively affect the cone–bipolar transmission.

Fig. 3 Effect of polarisation of an external horizontal cell on a bipolar cell. *a*, Potential changes of the external horizontal cell; *b*, responses of the bipolar cell recorded simultaneously with *a*; *c*, responses of the same bipolar cell during hyperpolarisation of its membrane by current. Recording conditions were the same as in Fig. 1 except that the current used to polarise the horizontal cell was 13 nA.



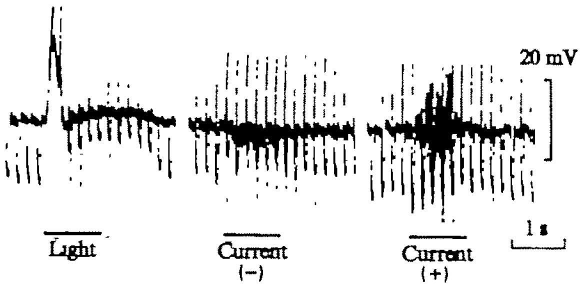


Fig. 4 Bridge records of bipolar cell responses to light (left) and to polarisation of an external horizontal cell by current (middle and right). Conditions of the bridge records were the same as in Fig. 2. The relatively large amount of current (20 nA) necessary to polarise the external horizontal cell generated an electrode noise, which was also picked up capacitatively in the bipolar cell records. Although the bridge records shown here are partly masked by such noise, it is seen that the hyperpolarising response to polarisation of the horizontal cell is accompanied by a decrease and the depolarising response by an increase in the membrane resistance.

The effect of polarisation of intermediate horizontal cells on the bipolar cells were clearly observed in all of the 11 pairs studied. On the other hand, the effect of polarisation of L-type external horizontal cells were observed in 5 out of more than 20 pairs studied. The effect was not prominent even in these 5 units. One reason for such results is that the input resistance of external horizontal cells is generally low which makes it difficult to polarise them sufficiently to affect the bipolar cells because of the restriction on the current flowing through the fine electrodes. It is also probable that the large bipolar cells receive a relatively small number of inputs from cones which mediate this effect.

The effect of polarisation of C-type horizontal cells on the on-centre bipolar cells was also studied in several pairs. But, so far we have been unable to detect any changes in the bipolar cells. It has been reported from morphological studies on goldfish retina that the C-type cells have direct connections with either blue or green cones but not with rods or red cones[12], and that a certain type of large bipolar cell has connections with rods and red cones but not with blue or green cones[13]. Although it is difficult to exclude the possibility that the current passed is not large enough to polarise the cell because of its low input resistance, the results probably indicate that the C-type cells do not affect the type of on-centre bipolar cells studied because they do not share the common photoreceptors.

Change in synaptic channel gating during neuromuscular development

FORMATION of neuromuscular synapses involves accumulation of acetylcholine receptors (AChRs) in the postsynaptic membrane[1-5]. The ionic channels associated with synaptic AChRs differ from the AChR channels present in the surface membrane of non-innervated muscle fibres. In particular, the mean open time of synaptic channels is much shorter than that of non-synaptic channels[6-10]. The question therefore arises at which stage of neuromuscular development the gating properties of synaptic channels become similar to those observed in adult junctions. The experiments described here show a difference in the mean open time of channels in early neonatal and adult rat endplates and suggest that a change in gating behaviour takes place during postnatal development.

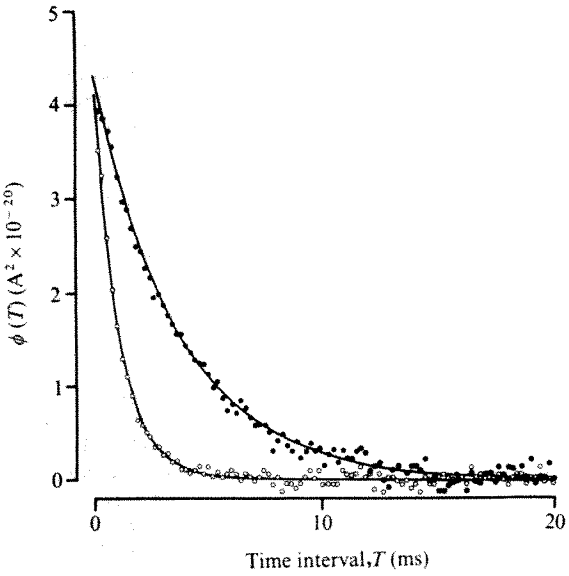

Fig. 1 Autocorrelation functions of ACh-induced current fluctuations recorded from voltage-clamped endplates of rat soleus muscle on postnatal days 8 (●) and 18 (○). Data points represent value of autocorrelation function $\phi(T)$ for different time intervals T. Mean ACh-induced currents were $I = 25$ nA and $I = 22$ nA, respectively. Membrane potential was clamped to −70 mV; temperature 22°C. Clamp currents before and during application of ACh were recorded on magnetic tape at low and high gain. The high gain record was bandpass filtered (1 Hz–2.5 kHz, 48 dB per octave roll off). High gain records were digitised at 200µs intervals and their a.c.f. calculated on a SAICOR auto-cross correlation analyser. Typically current samples of 6–12 s duration were analysed. a.c.fs of control and of ACh-evoked current samples were stored in a PDP 11/34 computer. The a.c.f. of the control sample was subtracted from the a.c.f. of the ACh-induced current sample. The resulting data points were displayed on an oscilloscope screen together with a machine-generated exponential (solid lines) corresponding to the expression $\phi(T) = \sigma^2 \cdot \exp(-T/\tau)$ where σ^2 represents the total variance of current fluctuations, and τ the a.c.f. decay time constant. For the a.c.fs shown, the curve-fitting yielded values of 3.9 ms (●) and 1.0 ms(○) for the decay time constant τ. Estimates of single channel conductances γ were obtained according to $\gamma = (\sigma^2/I)/(V - V_{rev})$ where V is the holding potential and V_{rev} the reversal potential (assumed to be 0 mV). The value of σ^2 is obtained from the extrapolated ordinal intercept of the fitted exponential. The single channel conductances were estimated as $\gamma = 25$ pS (day 8) and $\gamma = 27$ pS (day 18). All experiments were carried out in a solution containing (mM): NaCl, 140; KCl, 2; $MgCl_2$, 5; KH_2PO_4, 1; $NaHCO_3$, 12; pH 7, 2, oxygenated with 95% O_2 and 5% CO_2.

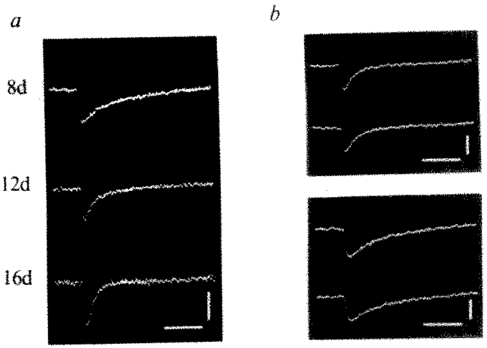

Fig. 2 Time course of m.e.p.cs at different stages of postnatal development. *a*, Change of soleus m.e.p.c. decay time course between postnatal days 8 and 16. Representative examples of single m.e.p.cs at different days after birth are shown. Note complex decay of m.e.p.cs on postnatal day 12. Recordings were made from soleus muscles of littermates. Membrane potential was clamped to −70 mV, 21–23°C. m.e.p.cs were recorded on magnetic tape and were replayed into a PDP-11/34 computer at a sampling rate of 20 kHz. Individual m.e.p.cs were displayed on an oscilloscope screen together with either one or the sum of two machine-generated exponentials which were fitted to the m.e.p.c. decay by eye. In the case of m.e.p.cs with doubly exponential decays one exponential was first fitted to the m.e.p.c. tail and subsequently another one to the difference between the data points and the extrapolated slower exponential. The mean $\bar{\tau}$ values in each fibre were on day 8: 4.6 ± 0.3 ms; on day 12: 1.1 ± 0.1 ms for the fast and 4.5 ± 0.3 ms for the slow component of m.e.p.c. decay; and on day 16: 1.2 ± 0.2 ms. Mean ± s.e.m., values from 10 individually measured m.e.p.cs were averaged in each fibre. Similar results were obtained with two other litters. Staining of endplate acetylcholinesterase activity by the Karnovsky method[17] did not show in the light microscope any obvious change in the staining intensity during this period. Calibration bars represent 4 ms and 2.5 nA. *b*, Recordings of m.e.p.cs on postnatal day 8 from neuromuscular junctions of omohyoideus (upper two traces) and soleus (lower two traces) muscle of the same rat. The average values of m.e.p.c. decay time constants were $\bar{\tau} = 1.3 \pm 0.1$ ms for the omohyoideus endplate and $\bar{\tau} = 4.3 \pm 0.2$ ms for the soleus endplate, averaging 10 individual m.e.p.cs in each experiment. Calibration bars represent 2 ms and 2 nA.

Experiments were performed at 20–23°C on isolated soleus and omohyoideus muscles taken from newborn rats between 1 and 18 d of age. Endplates were voltage clamped to −70 mV with a conventional two-microelectrode clamp. Acetylcholine (ACh) was released iontophoretically to induce steady endplate currents (e.p.cs) of 20–50 nA average amplitude. Channel mean open times were estimated from the autocorrelation function (a.c.f.) of fluctuations of the e.p.c. around its mean value. Assuming a simple two-state model of channel gating[6,11,12], the mean channel open time is given by the value of the decay time constant τ of the a.c.f.[7,12].

Figure 1 shows the a.c.fs of ACh-evoked e.p.c. fluctuations recorded from voltage clamped soleus endplates on postnatal days 8 and 18. The a.c.f. decay was singly exponential in both experiments but the decay time constants differed considerably. The value of τ on day 8 was 3.9 ms, which is about four times longer than the value of 1.0 ms found at the day 18 endplate. In seven experiments carried out before day 8, τ was 3.6 ± 0.2 ms (mean ± s.e.m.). This is comparable to the value found for channels in the extrasynaptic membrane of adult denervated[8] or early neonatal fibres (B.S. and H.R.B., unpublished) and for synapses formed *in vitro*[13]. Conversely, the mean channel open time observed in endplates on day 18 had an average value of $\tau = 1.0 \pm 0.1$ ms (four endplates), which is identical to that found in adult endplates[8,10,14]. From around postnatal day 8 to around day 17, however, the a.c.f. decay could be fitted adequately only by the sum of a fast and a slow exponential. Their average time constants were $\tau_{fast} = 1.0 \pm 0.1$ ms and $\tau_{slow} = 3.9 \pm 0.1$ ms (seven endplates). These are very similar to the time constants found at adult (≥18 d) and early neonatal (≤8 d) endplates, respectively. The amplitude of the fast component increased

0028-0836/78/0276—0401$01.00

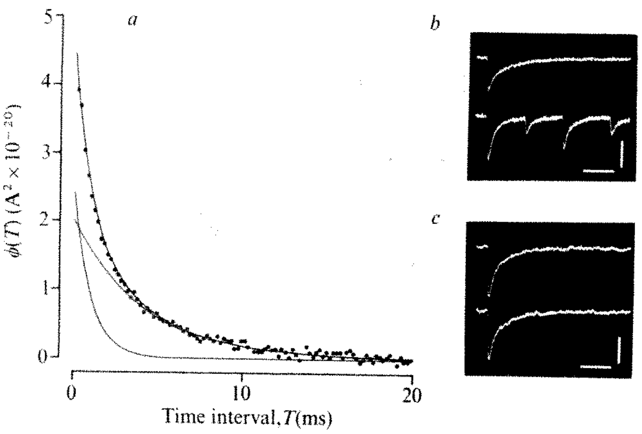

Fig. 3 Presence of two channel populations with different mean open times in neonatal omohyoideus endplate membrane. *a*, Autocorrelation function of endplate current fluctuations induced by iontophoretic ACh application on postnatal day 2. Data points represent value of the a.c.f. $\phi(T)$ for different time intervals T. The sum of two single exponentials, each of the form given in Fig. 1, was fitted to the data points (line drawn through data points). The two other lines represent the single exponentials. The time constants were $\tau_{\text{fast}} = 1.1$ ms for the fast and $\tau_{\text{slow}} = 3.9$ ms for the slow exponential. The ratio of their variances is $\sigma^2_{\text{fast}}/\sigma^2_{\text{slow}} = 1.18$. The slow exponential was first fitted to the tail of the a.c.f. decay, and subsequently the fast exponential was fitted to the difference between the data points and the extrapolated slow exponential. Membrane potential: −70 mV; 23°C. Mean ACh-induced endplate current was 21 nA. *b*, Recordings of m.e.p.cs on the same fibre as in *a*. m.e.p.c. decay is split into fast and slow component. The decay time course can be fitted by the sum of two exponentials with the time constants $\bar{\tau}_{\text{fast}} = 1.2$ ms and $\bar{\tau}_{\text{slow}} = 4.4$ ms. Mean values from 20 individually measured m.e.p.cs. *c*, Focal extracellular recordings of m.e.p.cs on postnatal day 4 from a voltage-clamped fibre (−70 mV, 22 °C). m.e.p.c. decay shows clear splitting in two decay phases and can be fitted by the sum of two exponentials. The respective time constants are $\bar{\tau}_{\text{fast}} = 1.0$ ms and $\bar{\tau}_{\text{slow}} = 5.3$ ms. The calibration bars represent 5 ms and 1 nA for *b* and 5 ms and 0.5 mV for *c*.

gradually during this transition period, whereas the amplitude of the slow component decreased correspondingly suggesting that from postnatal day 8 onwards the number of endplate channels with a short mean open time increases up to postnatal day 18 when all channels have fast kinetics.

Mean channel open time of junctional AChR channels can also be estimated from the time course of miniature endplate currents (m.e.p.cs). The falling phase of an m.e.p.c. in adult endplates is a single exponential the time constant of which, $\bar{\tau}$, approximately equals the mean open time of ACh-activated channels[11,15]. Developmental changes in the mean open time of junctional AChR channels should therefore be reflected in the m.e.p.c. decay time course. This is illustrated in Fig. 2*a* which shows examples of m.e.p.cs recorded from soleus endplates at various times after birth. To postnatal day 8 the m.e.p.c. decay is singly exponential with a mean value for $\bar{\tau}$ of 4.7 ± 0.2 ms (five endplates). This is four to five times greater than the value reported for adult endplates[14]. From around day 8 to around day 17, m.e.p.cs decayed with two time constants. From day 18 onwards m.e.p.c. decays were singly exponential again but with a much shorter time constant than is found in early neonatal fibres, the average value of $\bar{\tau}$ being 1.2 ± 0.1 ms (four endplates). During the transition period the m.e.p.c. decay could be satisfactorily fitted by the sum of two exponentials. Their time constants were similar to those of m.e.p.c. decays observed in early neonatal and adult endplates, respectively. The fast component becomes relatively more pronounced with age. For example, comparing measurements at four endplates on days 9 and 17 the average amplitude ratio of the fast to the slow component increased from 0.34 to 3.4.

A similar change in mean channel open time was observed in neonatal omohyoideus muscle, but it occurred earlier in postnatal development than in the soleus muscle. This is illustrated in Fig. 2*b*, which shows m.e.p.c. recordings from endplates in the omohyoideus and soleus muscles of the same rat at day 8. m.e.p.cs of the omohyoideus muscle decayed much faster than m.e.p.cs recorded from the soleus endplate. Their $\bar{\tau}$ value is comparable to that of m.e.p.cs in adult fibres already at this age. To determine the onset of the transition in channel gating in omohyoideus muscle, m.e.p.cs were recorded on postnatal days 1 and 2. In three out of four endplates studied on day 1 and in all four fibres studied on day 2, m.e.p.cs with doubly exponential decays were observed (Fig. 3*b*, *c*). The time constant of the fast component was $\bar{\tau}_{\text{fast}} = 1.2 \pm 0.1$ ms (seven endplates) comparable to the $\bar{\tau}$ value of m.e.p.cs in adult fibres. The average ratio of the slow to fast time constant was 4.3. Similarly the a.c.f. of ACh-induced e.p.c. fluctuations is fitted best by a double exponential decay during the first postnatal week (Fig. 3*a*) with the average time constants $\tau_{\text{fast}} = 1.2 \pm 0.1$ ms and $\tau_{\text{slow}} = 4.6 \pm 0.2$ ms (four endplates). From day 8 onwards only a fast component was resolved in both a.c.f. and m.e.p.c. decays, their respective time constants being $\tau = 1.0 \pm 0.08$ ms (four endplates) and $\bar{\tau} = 1.3 \pm 0.1$ ms (six endplates). This shows that synaptic channels in omohyoideus muscle have fast kinetics characteristic of the adult endplate, earlier during development than do those of soleus endplates. The fact that m.e.p.c. decays showed a fast component on postnatal day 1 suggests that in omohyoideus muscle a considerable fraction of adult-type channels is already present at birth.

Assuming neuromuscular synaptogenesis in rat begins at day 15 of gestation in the omohyoideus and at day 17 in soleus muscle[16], the experiments would indicate that a conversion of channels from an 'embryonic' to the adult type occurs in omohyoideus muscle between 6 and 14 d and in soleus between 13 and 22 d after the initial signs of neuromuscular transmission. It might be asked what influence causes the change of synaptic channel gating properties at a particular stage of development and why there is a difference between the omohyoideus and the soleus muscle? Neck muscles become active before the muscles of the lower extremities[16] and it is possible that earlier usage of neck muscles, for example during suckling, might cause this difference. Alternatively, maturation of neuromuscular junctions might be slower in red than in white muscle fibres.

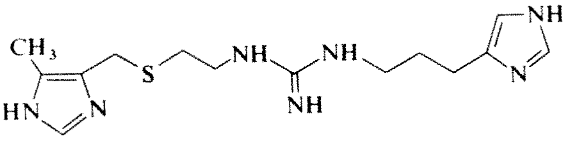
Impromidine (SK&F 92676) is a very potent and specific agonist for histamine H_2 receptors

PREVIOUSLY described selective agonists for histamine H_2 receptors are 4-methylhistamine[1], related congeners[2-6] and dimaprit[7]; these compounds are generally less potent than histamine. We have now found that *N*-[3-(imidazol-4-yl)-propyl]-*N'*-{2-[(5-methylimidazol-4-yl)methylthio]ethyl}-guanidine (impromidine, SK&F 92676 (I)) is extremely potent as an H_2-receptor agonist and briefly report its properties here.



I

The action of impromidine was studied *in vitro* on two tissues known to contain histamine H_2 receptors[1], the guinea pig right atrium and the rat uterus; the results are summarised in Table 1. On the atrium, impromidine had 48 times the potency of histamine whereas on the uterus it was 9.3 times as potent. The maximum responses achievable by the two agonists were compared by construction of complete cumulative dose–response curves (Fig. 1). On the guinea pig atrium impromidine achieved the same maximum response as histamine but on the isolated rat uterus the maximum response relative to histamine was only 80%, clearly suggesting that the compound has a lower efficacy than histamine. Cimetidine[8] (a histamine H_2-receptor antagonist) competitively inhibited the action on the guinea pig atrium, giving a dose-related parallel displacement of the dose–response curve to the right without depressing the maximum response (see Table 1 legend). In the absence of propranolol, 100 μM cimetidine completely suppressed the response to impromidine (in concentrations of up to 1 μM) on the atrium, suggesting that it had no significant agonist interaction with adrenergic β receptors.

On the atropinised guinea pig isolated ileum, a tissue known to contain H_1 receptors, impromidine failed to exert an agonist effect at concentrations up to 10 mM. This indicates that it has <0.001% the agonist activity of histamine at H_1 receptors. In fact, impromidine competitively antagonised the agonist effect of histamine on the ileum ($pA_2 = 5.47$; Table 1). Impromidine also failed to stimulate contractions of the ileum in the absence of atropine, indicating that it is not a muscarinic agonist. Indeed, impromidine competitively antagonised the agonist action of carbachol on this preparation ($pA_2 = 4.89$; Table 1).

In vivo, impromidine was found to be a highly potent stimulant of gastric acid secretion (Table 1). Compared with histamine, using the technique of the lumen-perfused stomach of the anaesthetised, vagotomised rat[7,9], impromidine had 16.8 times the potency of histamine as a gastric acid secretagogue. The time course of the agonist response to impromidine after rapid intravenous injection was similar to that obtained to histamine. The infusion rate for near maximal acid secretion was 0.015 μmol per kg per min (compared with histamine, 0.25 μmol per kg per min). In the anaesthetised cat, impromidine was ~27 times as potent as histamine in stimulating gastric acid secretion, based on a comparison of the infusion rates producing 50% of the maximal response. As found with dimaprit[7], the maximal response seemed to be greater than that

Fig. 1 Isolated guinea pig right atrium; cumulative dose–response curves to histamine (●) and SK&F 92676 (○). Each point is the mean of 10 observations ± s.e.m. 0.5 μM propranolol was present in the bathing fluid.

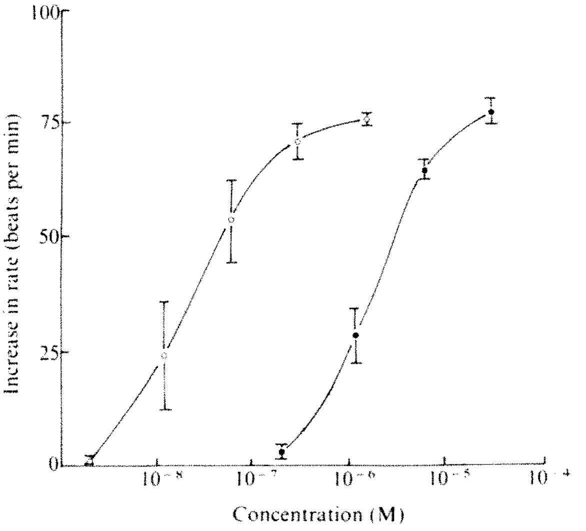


Table 1 Impromidine agonist activities, relative to histamine = 1

Preparation	Agonist activity mean (with 95% confidence limits)	% Maximum of histamine response (mean ± s.e.m.)	*n*
Guinea-pig ileum*	$<10^{-5}$		
Guinea-pig atrium†‡	48.1(37.6–60.1)	98.7 ± 3.6	10
Rat uterus†	9.3(5.7–15.2)	80.2 ± 2.6	22
Rat gastric acid secretion	16.8(11.3–27.1)	ND	16
Cat gastric acid secretion	~27	114 ± 18	5
Heidenhain pouch dog	~22	118 ± 11	5

SK&F 92676 was used as the trihydrochloride, a colourless crystalline solid, $C_{14}H_{23}N_7S$, 3HCl, of molecular weight 430.06 and melting point 198–200°C. It is very soluble in water and posesses three basic groups; a 3×10^{-3} molar solution (0.13% w/v) gives a *p*H of approximately 4.5. At this *p*H, or at *p*H 7.4, solutions are stable for at least 30 d at 20°C. For the *in vivo* studies, solutions were made up in normal saline. Rat gastric acid secretion data were obtained using lumen-perfused stomach of the anaesthetised, vagotomised rat[7,9] in a 2+2 Latin square assay. Cat gastric acid secretion was obtained from anaesthetised cats fitted with an acute gastric fistula and gastric juice was collected by drainage under gravity[7]. Dose–response curves to intravenous infusions of the agonist were constructed as described for the dog in Fig. 2. Conscious dogs were fitted with Heidenhain pouches which had been prepared 1–3 yr previously. Dose–response curves were constructed as described in Fig. 2. ND, not determined.

* Agonist assay on the ileum in the presence of 1 μM atropine[7]. Other actions: H_1-receptor antagonism of histamine, regression of log (DR–1) on log (concentration of SK&F 92676) ($n = 12$) had a slope of 0.95 ± 0.18 and gave $pA_2 = 5.47$ (95% confidence limits 5.16–5.74). Antagonism of carbachol, regression of log (DR–1) on log (concentration of SK&F 92676) ($n = 12$) had a slope of 0.95 ± 0.26 and gave $pA_2 = 4.89$ (95% limits 4.18–5.41).

† Comparative assays in the presence of 0.5 μM propranolol using a 2+2 Latin square design[7]. The ED_{50} values for SK&F 92676 were, respectively, 0.025 μM and 0.18 μM on atrium and uterus.

‡ Cimetidine $pA_2 = 6.53$ (6.09–6.98) ($n = 15$), not significantly different from the value against histamine[8] ($pA_2 = 6.10(6.04–6.17)$). The slope of the regression of log (DR–1) on log (concentration of cimetidine) = 0.81 ± 0.21, not significantly different from unity.

Table 2 Blood pressure responses to doses of impromidine maximal for gastric acid secretion

Species	Dose of SK&F 92676 (μmol kg^{-1} min^{-1})	Mean fall in blood pressure (mm Hg)	Mean increase in pulse pressure (mm Hg)
		(*n* = 4)	
Rat	0.015	27	ND
Cat	0.0032	27	20
Dog	0.0008	27	14

0028–0836/78/0276—0403$01.00

to histamine, but the difference was not statistically significant. The infusion rate for a maximum response was 0.0032 μmol per kg per min. In conscious Heidenhain pouch dogs, impromidine had ~22 times the potency of histamine (Fig. 2). The maximum response to impromidine was significantly greater than that obtained to histamine ($P = 0.05–0.025$). Maximal secretion was obtained at an infusion rate of 0.0008 μmol per kg per min (compare with histamine 0.022 μmol per kg per min). In all species studied the secretory response to impromidine was inhibited by histamine H_2-receptor antagonists. In the Heidenhain pouch dog, an infusion of cimetidine at 10 μmol per kg per h produced a mean inhibition of 86% ($n = 6$) of maximal acid secretion; this is comparable with that obtained against histamine for the same dose of cimetidine.

Blood pressure and gastric acid secretion were measured simultaneously in the anaesthetised rat and cat preparations and also in the acutely fistulated anaesthetised dog. The results shown in Table 2 indicate that at doses maximal for the stimulation of acid secretion, impromidine, in contrast to histamine, produced only small changes in mean blood pressure and in pulse pressure. Impromidine has been shown to be a specific agonist at histamine H_2 receptors. The lack of marked effects on the cardiovascular system at a dose level maximal for acid secretion suggests that impromidine may be useful as a diagnostic agent in man for the estimation of the maximal secretory capacity of the stomach in patients with gastrointestinal disease. Preliminary studies are reported elsewhere[10,11].

Subacute repeated dose studies have been carried out in the rat and dog for up to 14 d at dose levels >10 times the dose required for maximal stimulation of gastric acid secretion. No toxic effects which might limit the use of impromidine were apparent from these studies (G. B. Leslie, unpublished observations). Full details will be reported elsewhere.

The most interesting feature of the pharmacology of impromidine is its high potency compared to histamine. From the pharmacological analysis it seems that this increased potency is the result of an increased affinity of the compound for H_2 receptors rather than an increase in efficacy (using Stephenson's nomenclature[12]). This is obvious for the uterus preparation where impromidine is not a full agonist, although more potent than histamine; it would seem that in comparison with histamine many more receptors have to be occupied by impromidine to achieve a response. The high affinity of impromidine relative to histamine should make this a useful agent for binding studies at H_2 receptors.

The chemical structure poses interesting questions in relation to the pharmacological activity. Impromidine is a guanidine derivative having two different imidazolylalkyl substituents (Table 3, R_1 and R_2 in II), and it is instructive to compare it with analogous guanidines (Table 3, III and IV). The guanidine III (SK&F 91486) is a weak partial agonist at H_2 receptors[13] and must have a low efficacy relative to histamine. Adding the substituent R_2 to structure III gives impromidine and results in a full agonist on the atrium and in a 1,000-fold increase in potency. The group R_2 is, however, a structural feature of H_2-receptor antagonists (for example, metiamide[14,15] and cimetidine[8]) and, furthermore, the analogous guanidine IV (SK&F 92408) is an antagonist showing no agonist activity[16], suggesting that R_2 is associated with affinity but not with efficacy. Thus, a chemical group which contributes affinity in antagonist structures apparently converts a weak partial agonist (Table 3, III) into an agent (impromidine) which has increased efficacy as well as increased affinity. This result has important implications in considering drug–receptor interaction.

Fig. 2 Dog gastric secretion; dose–response curves to intravenous histamine (●) and SK&F 92676 (○) in the conscious Heidenhain pouch dog. Each point is the mean of five experiments ± s.e.m. Dose–response curves to intravenous infusion of the agonist were constructed using a stepwise doubling increment in the dose, each dose level being infused for 1 h and the mean of the acid output in the last two 15-min samples being taken to calculate the dose–response curve.

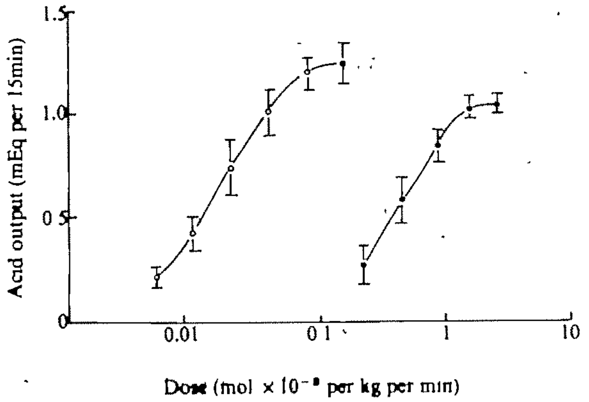

Table 3 Chemical structures of impromidine (SK&F 92676) and related guanidines

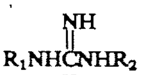

$$R_1NH\overset{\overset{NH}{\|}}{C}NHR_2$$

II

	R_1	R_2	H_2-receptor activity
I SK&F 92676			Potent agonist
III SK&F 91486		H	Weak partial agonist
IV SK&F 92408	CH_3		Antagonist

SK&F 91486 has 4% of the potency of histamine on the guinea pig isolated atrium but achieves only 70% of the maximum response relative to histamine; it competitively antagonises histamine ($pA_2 = 4.65$)[13]. These reported[13] results were obtained in the absence of propranolol; subsequent studies have shown that in the presence of propranolol, SK&F 91486 only attains 30.8±3.0% (mean±s.e.m.) of histamine's maximum response. On the rat isolated uterus (in the presence of propranolol) it has 6.5% of the potency of histamine and achieves only 27% of the maximal response[13]. SK&F 92408 competitively antagonises histamine[16], pA_2 4.80 (atrium), 5.26 (uterus).

We thank D. W. Hills for his contribution to the original synthesis of impromidine, and Dr D. H. Jenkinson for discussion.

A new dopaminergic prodrug

THE clinical treatment of parkinsonism with the dopamine (DA) precursor L-dopa has certain drawbacks[1] and there are relatively few drugs which directly stimulate DA receptors (although there are many which block them, such as the neuroleptics). There is thus great industrial, academic and clinical interest in the development of new DA-receptor agonists[1]. Recently much interest has been given to 2-amino-6, 7-dihydroxytetrahydronaphthalene (ADTN)(Fig. 1), which is known from various *in vitro* and *in vivo* studies[2–10] to be a potent, selective and long-acting DA agonist. Two drawbacks to its more widespread study, however, are that the original synthesis was not easy, consisting of eight steps[11], and like DA, it does not readily pass the blood–brain barrier, so that it must be administered to animals intraventricularly. Although *in vivo* ADTN is not the most potent member of its group of 2-aminotetralin derivatives[12], it has the advantage of being structurally very similar to DA, but metabolically more stable. We have developed an improved, simplified synthesis of ADTN consisting of four steps[13] and we now describe how we have effected the passage of the drug into the brain. In addition to their practical and clinical implications, our results throw new light on the *in vivo* action of this drug.

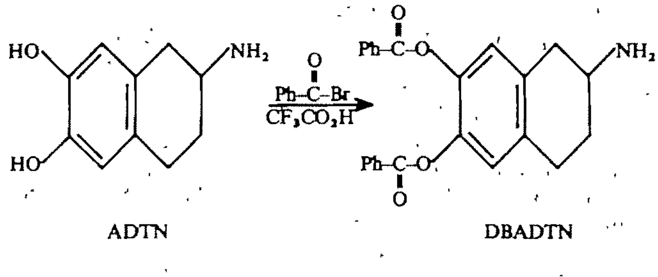

Fig. 1 The molecular weight of ADTN is 179 and that of DBADTN 387; thus, a dose of 50 mg per kg DBADTN is equivalent to 23 mg per kg ADTN.

As lipid-soluble drugs rapidly pass the blood–brain barrier, we synthesised a 'prodrug' from ADTN. A prodrug is a derivative that has certain desirable properties, for example, enhanced lipid solubility, which the parent molecule does not possess, and that can be converted back (by enzymes) into the active species within the body. The synthesis consisted of making a diester derivative of the catechol function (Fig. 1) which reduces the polarity of the parent molecule and makes it more lipid soluble. It was anticipated that after entering the brain the diester-prodrug would be converted back to ADTN by enzymatic hydrolysis. The dibenzoyl ester (DBADTN) was chosen as it was predicted on theoretical grounds that its rate of hydrolysis would be slower than that of the simple aliphatic esters[14], an important point if sufficient prodrug is to survive hydrolysis outside the brain, to pass into this organ. The diester was readily prepared in a yield of 74% by treating ADTN in trifluoroacetic acid with benzoyl bromide at room temperature (Fig. 1). The presence of trifluoroacetic acid ensures that only the catechol function is esterified and that the amino group is not affected. Analytical and spectral data were consistent with the proposed structure, and details will be published elsewhere.

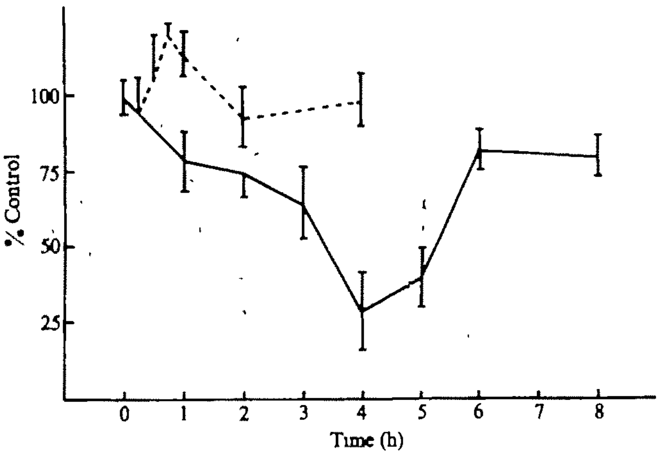

Fig. 2 Effect of DBADTN on HVA and DA concentrations in rat corpus striatum. Female Wistar rats (150–200 g) received 50 mg per kg DBADTN i.p. in a vehicle consisting of 30% ethanol, 30% water and 40% polyethylene glycol 400. HVA and DA were determined in rat corpus striatum using previously described methods[19,30]. Control values (mean ± s.e.m. (number of determinations)) for HVA were 0.52 ± 0.03 (27) µg per g and for DA, 5.68 ± 0.29 (5) µg per g wet weight. A statistical analysis consisting of an analysis of variance followed by the Newman–Keuls test[31] on the absolute values of HVA and DA showed that the decrease in HVA concentration at 3, 4 and 5 h was significantly different from control values at the 5%, 1% and 1% level, respectively. None of the changes in DA concentration were significant at the 5% level. Each point is the mean ± s.e.m. of 7–8 determinations for HVA and 4–8 for DA. – – –, DA; ——, HVA.

The idea that the prodrug would enter the brain and be hydrolysed to ADTN was tested by injecting 100 mg per kg DBADTN intraperitoneally (i.p.) into a female Wistar rat, killing the animal 45 min later, and rapidly dissecting the corpus striatum from the rest of the brain. The ADTN was isolated and derivatised with pentafluoropropionic anhydride using a modification of the method of Wilk and Stanley[15] for gas chromatography–mass spectrometry mass fragmentographic analysis. By monitoring the peaks at m/e 307 and 454 from the acylated derivative of ADTN, it was unequivocally shown that ADTN was present in the corpus striatum and the rest of the brain. DA agonists are known to decrease DA turnover in the corpus striatum as reflected by a lowering of the concentration of homovanillic acid (HVA)[16–18], one of the main metabolites.

The effect of 50 mg per kg DBADTN (equivalent to 23 mg per kg ADTN) on HVA levels in the corpus striatum of rats was studied over 8 h (Fig. 2). A 70% decrease of control levels was found after 4 h but by 6 h the HVA concentrations were almost normal. This slow onset of the maximum effect, in comparison with the rapid effect of apomorphine[19], is probably a result of the delayed concentration rise of ADTN in the brain brought about by enzymatic hydrolysis from the prodrug. Preliminary experiments indicate that lower doses of the prodrug also produce decreases in striatal HVA levels in a dose-related manner. As α-methyldopa is known to produce a very similar effect on HVA levels after the same time period[20] as well as lowering endogenous striatal DA levels, and as this may be brought about by its conversion to α-methyldopamine (which can be viewed as a ring-opened lower homologue of ADTN), the effect of DBADTN on striatal DA levels was also examined (Fig. 2). It was found however, that there was no statistically significant depletion of DA over a 4-h period. To ensure that the effect on

0028-0836/78/0276—0405$01.00

HVA levels was due to ADTN produced in the brain and not to entry of ADTN produced by enzymatic hydrolysis outside the brain, 30 mg per kg of ADTN itself was injected i.p. into rats; however, after 4 h there was no significant lowering of HVA levels ($92\pm3\%(n=8)$ of controls) in the striatum.

It is known that the increase in DA turnover, as reflected in elevated HVA levels, which is caused by DA-receptor antagonists such as the neuroleptics, can be attenuated by DA agonists[17,21]. We were also able to demonstrate this with DBADTN in a dose-dependent manner; thus, the effects of 0.50, 0.25 and 0.05 mg per kg haloperidol could all be attenuated by administration of 50 mg per kg DBADTN (Fig. 3).

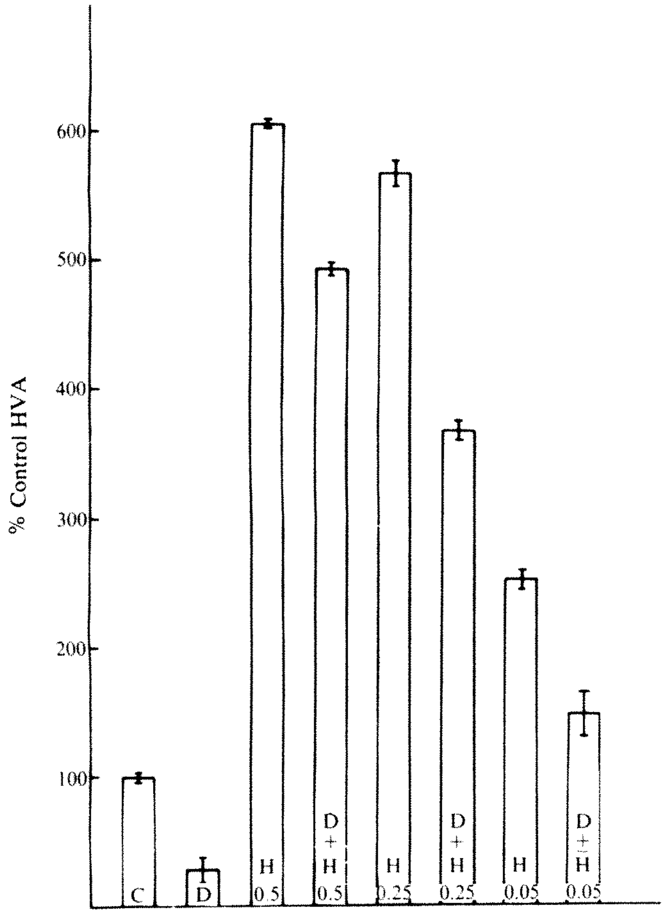

Fig. 3 Effects of DBADTN and various doses of haloperidol, alone and in combination, on HVA levels in rat corpus striatum. Female Wistar rats (150–200 g) received 50 mg per kg DBADTN (D) i.p. in the standard vehicle and 2.5 h after 0.50, 0.25 or 0.05 mg per kg haloperidol (H) i.p., the animals were then killed 1.5 h after the haloperidol injection. The HVA concentration in the corpus striatum was determined as previously described[19], control values (mean ± s.e.m. (number of determinations)) were 0.36 ± 0.01 (20) μg per g wet weight. Statistical analysis using Students t test on the HVA values in the experimental groups, haloperidol (H) against haloperidol (H) + DBADTN (D) showed that for the haloperidol doses of 0.5, 0.25, and 0.05 mg per kg the levels of significance were $P<0.01$ and <0.01 and <0.01, respectively. Each group is the mean ± s.e.m. for 7–8 determinations.

These results agree with the inhibition of the behavioural effects of ADTN by 0.5 mg per kg haloperidol[6]. It has now been shown that there are at least three DA receptors in the CNS, a postsynaptic and two 'presynaptic' receptors, one of which is probably located on the presynaptic nerve terminal, with the other near the DA cell body[22]. We have already presented *in vitro* evidence for an action of ADTN on the latter of these presynaptic DA receptors, that is, in the substantia nigra[23]. It was shown that in homogenates of this brain area, ADTN was as potent as DA in stimulating cyclic AMP production. It was therefore of interest to examine the effect of DBADTN (and hence ADTN) on the terminal presynaptic DA receptor using the γ-butyrolactone (GBL) model[22]. Administration of GBL to rats results in an inhibition of impulse flow in the dopaminergic presynaptic axons which causes a decrease in DA release coupled with a marked increase in its biosynthesis; this leads to a large rise in DA[22] and HVA[24] levels. The inhibition of these elevations by DA agonists is considered to be due to stimulation of presynaptic DA receptors on the axon terminal[22,24,25]. As shown in Fig. 4 the rise in HVA levels caused by GBL could be attenuated by pretreatment with DBADTN (compare G with D + G). This is compelling evidence for an action of ADTN on the presynaptic DA terminal[24]. Attempts to inhibit this effect of ADTN on HVA levels by blocking its uptake with benztropine[26] were without success, suggesting possibly that *in vivo* interaction with membrane presynaptic receptors is of more significance than is cytoplasmic accumulation of ADTN. *In vitro*, however, it has been shown[27] that benztropine does affect the ability of ADTN to interfere with DA turnover. Benztropine itself produced a lowering of HVA levels that was not statistically significant at the 5% level; Braestrup has also reported that it has no significant effect[28].

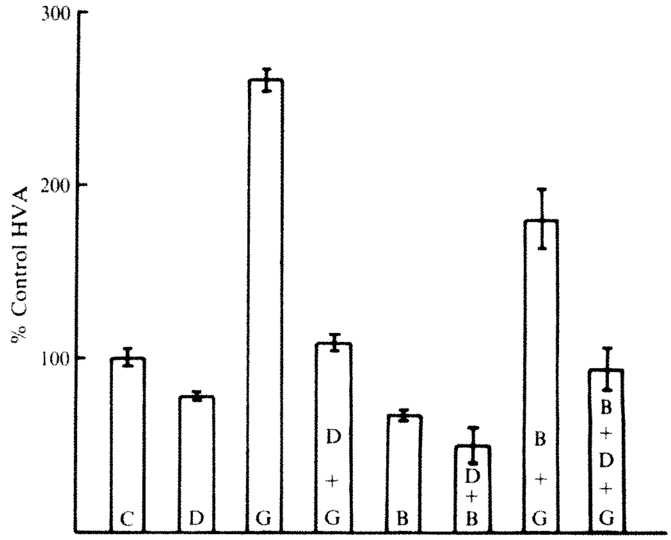

Fig. 4 Effect of DBADTN pretreatment on the GBL-induced rise in HVA levels in rat corpus striatum. Female Wistar rats (150–200 g) received 25 mg per kg benztropine[28] (B) i.p. and 10 min later 50 mg per kg DBADTN (D). 30 min after injection of D they were injected with 750 mg per kg γ-butyrolactone, GBL (G), and 90 min after this the animals were killed and HVA concentrations in the corpus striatum determined[19]. Control values were 0.54 ± 0.03 (14) μg per g wet weight (mean ± s.e.m.(number of determinations)). Statistical analysis (analysis of variance followed by the Newman–Keuls test[31]) on the HVA values showed that the differences between control (C) compared with G, and G compared with D + G were both significant at the 1% level. There was no significant difference at the 5% level between the groups D + G compared with B + D × G. Each group is the mean ± s.e.m. of 7–16 determinations.

We have demonstrated that it is possible to prepare a successful prodrug from a molecule that does not pass the blood–brain barrier. It should be stressed that the situation here is quite different from that occurring with the recently described esters of apomorphine[29] in that apomorphine itself can pass the blood–brain barrier and a reasonable amount of the free drug produced in the body by hydrolysis will probably pass into the brain. Second, we have shown that in addition to being able to interact with postsynaptic and nigral DA receptors, ADTN can also interact *in vivo* with DA receptors which are thought to be located on DA nerve terminals. We are now attempting to determine the concentration of ADTN in the corpus striatum and other brain areas and also to examine the effects of the prodrug on animal behaviour. The latter results may indicate whether or not the prodrug has any possible clinical potential.

Alterations in β-adrenergic receptor binding during ethanol withdrawal

CHARACTERISTIC features of ethanol withdrawal, including tremor, agitation, seizures, tachycardia and increased blood pressure, frequently develop in chronic alcoholics 6–60 h after the discontinuation of long-term heavy ethanol consumption[1–4]. Similar symptoms are seen in hyperadrenergic states such as anxiety and thyrotoxicosis[5,6]. There is evidence to suggest that augmented sensitivity to catecholamines in thyrotoxicosis is due to the development of β-adrenergic receptor supersensitivity in cardiac and skeletal muscle cell surfaces[7–10]. Propranolol, a β-adrenergic blocker, has been shown to control some of the clinical signs of ethanol withdrawal, such as arrhythmia, hypertension and tremor[11–13]. In addition, propranolol significantly decreases urinary excretion of noradrenaline during ethanol withdrawal[14]. These findings have led to the suggestion that peripheral manifestations of increased adrenergic activity in ethanol withdrawal are secondary to increased sympathetic neural outflow and that this increase in central catecholaminergic outflow may be the result of increased β-adrenergic receptor sensitivity in the alcohol withdrawal state in man[14]. We report here attempts to determine whether increased central and peripheral β-adrenergic receptor binding could be demonstrated in rats during ethanol withdrawal.

Table 1 Effect of chronic ethanol treatment on specific binding of ^{3}H-DHA to β-adrenergic receptors in brain and heart particulate fractions

Time after termination of ethanol treatment (h)	Brain		Heart	
	Control	Ethanol-treated	Control	Ethanol-treated

Rats were pair-fed a nutritionally complete liquid diet containing either 6.5% (v/v) ethanol or an equicaloric amount of sucrose for 60 d by a previously described method[15]. Ethanol provided 36% of the total calories for the chronically treated rats (daily intake approximately 12–14 g per kg). The purity of ^{3}H-dihydroalprenolol (DHA) (NEN) was tested by thin-layer chromatography[16]. The procedures for the preparation of brain and heart particulate fractions and measurement of specific binding of ^{3}H-DHA to β-adrenergic receptors have been described previously[17–19]. The results are shown as fmol of DHA bound per mg protein and are the means (±s.e.m.) of 5 or 6 determinations (each in triplicate) from 5 or 6 rats in each group. The concentration of ^{3}H-DHA was 2 nM in each binding assay.

* Significantly different from control ($P<0.05$), by Student's *t*-test.

Specific binding of ^{3}H-dihydroalprenolol (DHA) to brain and heart particulate fractions obtained from sucrose- and ethanol-fed rats is shown in Table 1. The specific binding of ^{3}H-DHA in heart and brain particulate fractions decreased by 43% and 23% respectively in the ethanol-fed group as compared with the sucrose-fed control rats at zero hour of termination of chronic ethanol treatment. The high concentration of ethanol in rat blood at this time suggests that the decrease in ^{3}H-DHA binding might be due to interference by ethanol with the drug–receptor interaction. To test this possibility, specific binding of ^{3}H-DHA to heart and brain particulate fractions was measured in the absence or presence of ethanol in the binding assay medium. Ethanol (2 mg ml^{-1}) did not decrease binding of ^{3}H-DHA to heart or brain particulate fractions. In addition, 10 rats were divided into two groups; group I being treated intraperitoneally with ethanol, 2.5 g per kg body weight, administered as a 12.5% (w/v) solution in normal saline, and group II, which served as the control, receiving an equal volume of normal saline. Rats were killed 2 h after drug administration, and brain and heart particulate fractions were prepared as described in Table 1. Specific binding of ^{3}H-DHA to these preparations obtained from control and ethanol-treated rats were the same. These observations suggest that the decrease in specific binding of ^{3}H-DHA to the heart and brain particulate fractions immediately after termination of chronic ethanol treatment is not due to interference by ethanol with the drug–receptor interaction.

One day after discontinuation of chronic ethanol treatment, the specific binding of ^{3}H-DHA to heart and brain particulate fractions was similar in sucrose- and ethanol-fed rats. On the other hand, 48 h after cessation of ethanol administration, the specific binding of ^{3}H-DHA increased by 75% in brain and 49% in heart as compared with control preparations. Seventy-two hours after withdrawal from chronic alcohol administration the specific binding of ^{3}H-DHA was enhanced by 67% in brain and 136% in heart.

The increased binding of ^{3}H-DHA in rat brain particulate fractions during the withdrawal state following chronic ethanol treatment suggests changes in either the number or the apparent affinity of β-adrenergic receptors for ^{3}H-DHA. Therefore, the equilibrium dissociation constants and maximal number of binding sites for the β-adrenergic receptor were determined graphically (Fig. 1). Enhancement of the binding of ^{3}H-DHA to β-adrenergic receptors in rat brain particulate fractions 48 and

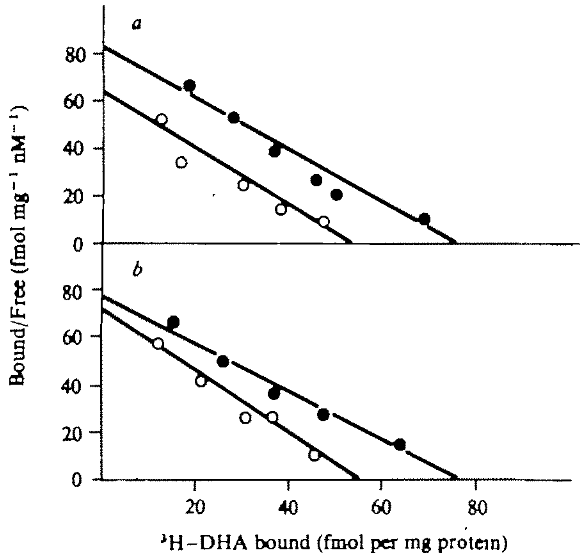

Fig. 1 Scatchard analysis of specific binding of ^{3}H-DHA in brain particulate fractions obtained from sucrose (○) and ethanol (●) fed rats at 48 h (*a*) and 72 h (*b*) after cessation of ethanol administration. The concentrations of ^{3}H-DHA used varied from 0.125 to 4 nM. Slopes and intercepts of the lines were determined by the method of least squares. The correlation coefficient, $r \geq 0.82$.

72 h after cessation of chronic ethanol intake appears to be due to an increase in the number of binding sites (Table 2).

Propranolol, a β-adrenergic receptor antagonist, has been shown to be of value in the management of withdrawal reactions of chronic alcoholism including augmented urinary excretion of noradrenaline[11-14]. These observations have led to the hypothesis that the peripheral effects of ethanol withdrawal may be a consequence of increased central β-adrenergic receptor sensitivity. The results described in the present communication provide experimental evidence in support of this hypothesis. In addition, present observations show that increased β-adrenergic receptor binding may occur both in the central nervous system and in peripheral tissues during ethanol withdrawal. Thus, the therapeutic efficacy of propranolol during ethanol withdrawal reactions may be mediated in part by its antagonism to the effects of increased central catecholaminergic outflow and in part by directly blocking hypersensitive β-adrenergic receptors in peripheral tissues.

The ethanol withdrawal state has been divided into two major components[1-4]. In mild reactions, the chief symptoms are sleeplessness and irritability, which appear within a few hours of withdrawal and disappear after 48 h. In severe reactions these symptoms are followed by tremulousness, hallucinosis, seizures, and arrhythmias which are most evident 2–3 d after ethanol withdrawal[1-4]. This suggests that the increase in β-adrenergic receptor sensitivity may contribute to the withdrawal reaction following the interruption of chronic ethanol intake.

Attenuated as well as increased accumulations of noradrenaline-stimulated cerebral cortical cyclic AMP have been reported with chronic ethanol treatment in rats and mice[20-22]. As noradrenaline may increase formation of cyclic AMP by interacting with either α-adrenergic or β-adrenergic receptors in brain, the results of French, Israel and their associates[20-22] fail to provide any conclusive evidence for a specific alteration of sensitivity of α-adrenergic or β-adrenergic receptors in chronic alcoholism.

The molecular mechanism for the increase in β-adrenergic receptor binding in rat heart and brain particulate fractions during the ethanol withdrawal state is not known. A variety of psychotropic drugs, such as antipsychotics[23], antidepressants[17] and amphetamine[19], have been shown to alter the sensitivity of dopaminergic and β-adrenergic receptors. Amphetamine and desipramine are known to affect noradrenaline transport at the catecholaminergic nerve endings[24,25]. The Na^+-dependent noradrenaline transport appears to be mediated through the activity of $(Na^+ + K^+)$-ATPase[26,27]. A marked activation in the number of $(Na^+ + K^+)$-ATPase molecules in several areas of brain and some peripheral organs has been observed during ethanol withdrawal in cats and rats[28-31]. It is suggested that this activation of $(Na^+ + K^+)$-ATPase may contribute to increased β-adrenergic receptor sensitivity in rat heart and brain following interruption of chronic ethanol intake.

Table 2 Effect of chronic ethanol treatment on the equilibrium dissociation constant (K_D) and maximal number of binding sites (B_{max}) of β-adrenergic receptors in rat brain

Time after termination of ethanol treatment (h)	Control B_{max} (fmol per mg protein)	Control K_D (nm)	Ethanol-treated B_{max} (fmol per mg protein)	Ethanol-treated K_D (nM)
0	62±6	0.71±0.06	45+7*	0.81±0.07
48	53±8	0.85±0.07	76±11*	0 91±0.06
72	55±9	0.77±0.05	76+9*	0.98±0.05

The specific binding of 5 concentrations of ^{3}H-DHA (0.125–4 nM) to β-adrenergic receptors in rat brain particulate fractions was assayed as described in Table 1. The equilibrium dissociation constants and maximal number of binding sites were estimated by Scatchard analysis, as described before[17-19]. Results shown are the mean (±s.e.m) of 5 determinations (each in triplicate) from 5 rats for each of the 5 concentrations of ^{3}H-DHA used

* Significantly different from control ($P < 0.05$), by Student's *t*-test.

The studies presented here suggest that increased β-adrenergic receptor binding in rat brain and peripheral tissues may contribute to the hyperadrenergic state of the withdrawal reaction of chronic alcoholism. These observations provide a rationale for the use of β-adrenergic antagonists in the management of the ethanol withdrawal reaction.

These studies were supported in part by grants from the NIHL and AHA, and a post-doctoral fellowship (to V.K.S.) from the Genessee Valley Heart Association. We thank Dr Ann Young for stimulating discussions.

Epidermal growth factor stimulates phosphorylation in membrane preparations *in vitro*

EPIDERMAL GROWTH FACTOR (EGF) forms a complex with plasma membrane receptors in intact cells that initiates a series of biochemical events resulting in increased cell growth *in vivo* and *in vitro*[1]. The interaction of EGF with membrane receptors has been demonstrated in crude membrane preparations[2], but no biochemical alteration of the membrane resulting from hormone binding has been detected. To clarify the molecular mechanisms regulating cell proliferation, specific biochemical reactions initiated by mitogens such as EGF need to be investigated in cell-free systems. As the human epidermoid carcinoma cell line A-431 has an extraordinarily high concentration of EGF receptors[3,4] (2–3 $\times 10^6$ receptors per cell), we have used a crude membrane preparation from these cells to look for an EGF-dependent alteration of membrane structure and/or function. We report here that (1) membranes may be prepared from A-431 cells that retain the ability to bind ^{125}I-labelled EGF in a specific manner, and (2) the binding of EGF to these membranes *in vitro* results in a marked stimulation of the phosphorylation of endogenous proteins in the presence of [γ-^{32}P]ATP.

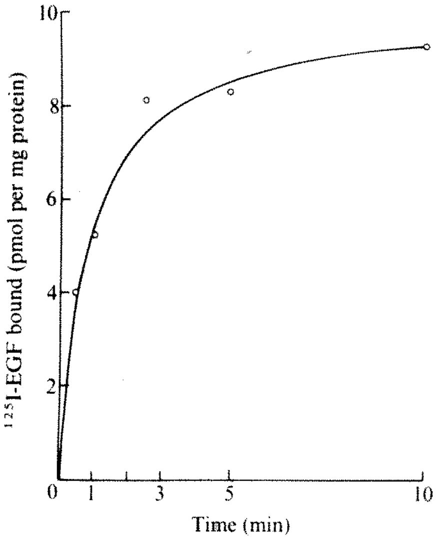

Fig. 1 Binding of ^{125}I-EGF at 0 °C to A-431 membranes. Membranes were prepared by the procedure described by Thom *et al.*[5] from A-431 tumour cells grown in Falcon culture dishes containing Dulbecco's modified Eagle's medium supplemented with 10% fetal calf serum and gentamycin. ^{125}I-EGF was prepared as reported by Carpenter and Cohen[6]. The binding reaction was carried out in a 200-μl reaction volume containing 20 mM HEPES buffer, *p*H 7.4, 0.1% bovine serum albumin (BSA), 12 μg of A-431 membrane protein (measured by the Bradford procedure[7] using γ-globulin as a standard), and ^{125}I-EGF (3.3×10^{-9}M). Nonspecific binding was measured in co-lateral reaction tubes which contained a 1,000-fold molar excess of unlabelled EGF (3.3×10^{-6} M) and did not exceed 4% of the total binding. The amount of ^{125}I-EGF bound to the membranes was determined by rapidly filtering the reaction mixture on Millipore EGWP filters, washing each filter with a total of 8 ml of 20 mM HEPES, *p*H 7.4, containing 0.1% BSA. The amount of radioactivity retained on each filter was determined by counting in a Nuclear Chicago γ-spectrometer. Storage of A-431 membranes at −70 °C for 2–3 months did not appreciably decrease the binding activity.

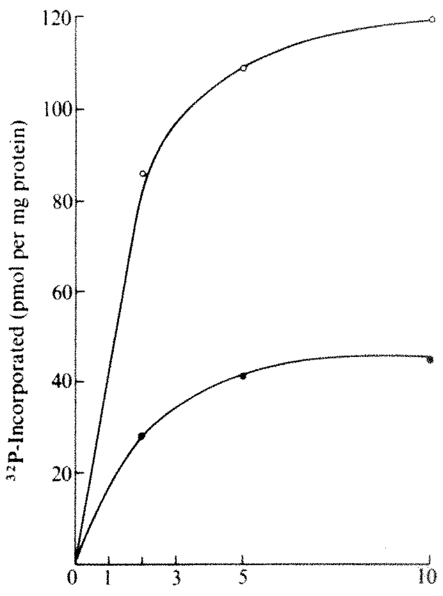

Fig. 2 Stimulation by EGF of the incorporation of ^{32}P-phosphate from [γ-^{32}P]ATP into cell membranes. The reaction mixtures contained A-431 membrane (27 μg protein), HEPES buffer (20 mM, *p*H 7.4), $MnCl_2$ (1 mM), [γ-^{32}P]ATP (15 μM, 8×10^5 c.p.m.), EGF (40 ng) and BSA (7.5 μg) in a final volume of 60 μl. The reaction tubes were placed on ice and preincubated for 10 min in the presence (○) or absence (●) of EGF. The reaction was initiated by the addition of labelled ATP and incubation at 0 °C was continued for the indicated times. The reaction was terminated by pipetting 50-μl aliquots on to squares (2 cm) of Whatman 3 MM filter paper and immediately dropping the paper into a beaker of cold 10% TCA containing 0.01 M sodium pyrophosphate. The filter papers were washed extensively with pyrophosphate-containing 10% TCA at room temperature, extracted with alcohol and ether, dried, and the radioactivity measured in a Nuclear Chicago gas-flow counter.

The specific binding of ^{125}I-labelled EGF at 0 °C to membranes prepared from A-431 tumour cells is shown in Fig. 1. In these conditions, the initial rate of binding is rapid (8 pmol of ^{125}I-EGF are bound per min per mg protein) and equilibrium is reached within 10 min. At equilibrium, approximately 18% of the hormone is membrane-bound at a specific binding activity of 9.0 pmol of EGF per mg protein. A-431 membranes, therefore, contain a concentration of EGF receptors comparable to the high levels detected in membranes prepared from human placenta[2].

Aliquots of the A-431 membrane preparation were used to determine whether the binding of EGF to membrane receptors was followed by a biochemical alteration of the membranes. As shown in Fig. 2, the addition of EGF to A-431 membranes produced a three- to fourfold stimulation of the phosphorylation of endogenous membrane proteins at 0 °C as judged by the transfer of ^{32}P-phosphate from γ-labelled ATP to membrane material. Figure 2 also shows that in the presence of EGF the initial rate of phosphorylation is increased from 16.7 to 50.0 pmol of ^{32}P-phosphate incorporated per min per mg protein. Membrane protein phosphorylation reached a maximal level by 10 min at 0 °C and a threefold higher level of ^{32}P-phosphate incorporation was achieved in the presence of EGF at all times examined.

We have partially characterised this EGF-stimulated reaction in isolated A-431 membranes and here are summarising our results, the details of which will be presented elsewhere. The ^{32}P incorporated into the membrane is trichloroacetic acid (TCA)-insoluble and only a small amount (20%) is removed by extractions with alcohol, ether and chloroform–methanol. Partial acid

0028-0836/78/0276—0409$01.00

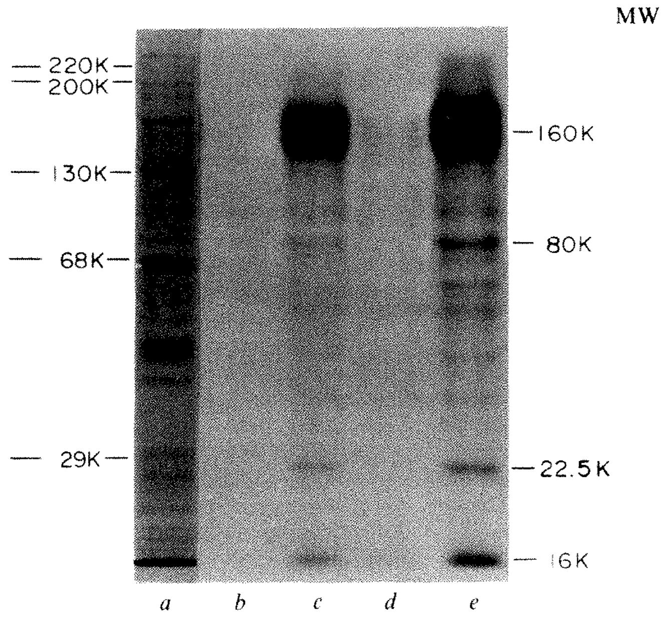

Fig. 3 Electrophoresis and autoradiography of A-431 membrane components incubated with [γ-^{32}P]ATP in the presence and absence of EGF. The phosphorylation of A-431 membranes was carried out at 0 °C in 40-µl reaction mixtures containing 30 µg of A-431 membranes, 20 mM HEPES, *p*H 7.4, 2 mM $MnCl_2$, 0.01% BSA and 15 µM [γ-^{32}P]ATP (20 Ci mmol^{-1}). EGF was added at a final concentration of 14×10^{-8} M immediately before the addition of ^{32}P-ATP, which initiated the reaction. The reaction was stopped after 1 or 5 min at 0 °C by the addition of 40 µl of Laemmli SDS sample buffer[8]. The mixture was boiled for 5 min and then subjected to SDS-gel electrophoresis (7.5% acrylamide) according to the method of Laemmli[8]. The gels were stained with Coomassie blue, vacuum dried and autoradiography carried out by exposing the gel to Kodak RP Royal X-O mat film for 2 d. Molecular weight (MW) standards used for calibration were erythrocyte spectrin, 240,000 and 220,000; skeletal muscle myosin, 200,000; β-galactosidase, 130,000; BSA, 68,000; carbonic anhydrase, 29,000. *a*, Coomassie blue stain of A-431 membrane components (30 µg of protein applied to the gel); *b–e*, autoradiography of A-431 membrane components phosphorylated in absence (*b*, *d*) and presence (*c*, *e*) of EGF for 1 min (*b*, *c*) or 5 min (*d*, *e*).

hydrolysis of the phosphorylated membranes and electrophoresis of the resultant mixture show that in both the control and EGF-dependent reaction the major phosphorylated product is phosphothreonine, indicating that the observed phosphorylations are directed mainly towards protein substrates. Both the endogenous membrane phosphorylation and the EGF-stimulated reaction depend on the presence of Mg^{2+} or Mn^{2+}; Ca^{2+} is ineffective. Maximal stimulation of membrane phosphorylation occurs in the presence of 3×10^{-8} M EGF. The presence of cyclic AMP or cyclic GMP (10^{-4}–10^{-6} M) has no discernible effect on the reaction. Both the basal and EGF-stimulated reaction are completely destroyed by heating the membrane for 10 min at 50 °C before the addition of [γ-^{32}P]ATP and EGF. As expected, the addition of unlabelled ATP to the reaction mixture diminishes the extent of phosphorylation. The specificity of the EGF-dependent reaction was examined by the addition of a wide variety of peptide hormones to the reaction mixture in place of EGF. We did not detect any effect of insulin, thyrotropin, follicle-stimulating hormone, growth hormone, glucagon, prolactin or luteinising hormone on the overall phosphorylation reaction. The addition of EGF to the A-431 membrane preparation seems to stimulate a protein kinase activity capable of using exogenous substrates as well as the endogenous membrane substrates. Several proteins, including histones and ribonuclease are phosphorylated when they are added to this system and their phosphorylation is stimulated two- to fourfold by the addition of EGF.

The membrane components which were phosphorylated *in vitro* in the presence and absence of EGF were analysed by SDS–polyacrylamide gel electrophoresis and autoradiography. The results shown in Fig. 3 indicate that during the first minute of incubation in the presence of EGF, membrane components having molecular weights of ~170,000 and ~150,000 are heavily phosphorylated. With continued incubation, additional membrane components are phosphorylated to a greater extent in the presence of EGF, most noticeably components with apparent MW of 80,000 and 22,500. The results also show that membrane components for which phosphorylation is increased in the presence of EGF seem to be phosphorylated in the absence of the growth factor, but to a lesser extent. Of course, these data do not show whether different sites on the same membrane proteins are phosphorylated in the presence and absence of EGF.

Thus, we have been able to demonstrate for the first time the modulation of a biochemical reaction in a cell-free membrane preparation as a consequence of the formation of EGF–receptor complexes. Following the binding of EGF, the capacity of these membranes to phosphorylate endogenous and exogenous proteins is markedly enhanced. The mechanism by which EGF enhances phosphorylation is not known; the receptor may possibly be a protein kinase, a regulatory subunit of a protein kinase or a regulator of phosphoprotein phosphatase. However, the observed net increase in phosphorylation may be an even more indirect consequence of the formation of EGF–receptor complexes. As neither the identity nor function of the phosphorylated membrane components is known, it is not possible to relate these findings to specific metabolic alterations, such as increased transport of nutrients and ions or induction of DNA synthesis, that are induced in intact cells by EGF. We have previously shown that after the binding of EGF to intact cells, this mitogen, probably as a hormone–receptor complex, is internalised by cytoplasmic vesicles[3,6]. It is not known, however, at what stage or stages in the binding and internalisation of EGF intracellular signals are generated which regulate cell growth. We suggest that the phosphorylation of membrane or membrane-associated components may be an initial event in the generation of these important signals. The effect of external stimuli or protein phosphorylation has been noted in many systems *in vivo*[9], and with insulin, by the use of sarcolemma-enriched membrane preparations *in vitro*[10].

Tubulin microheterogeneity increases with rat brain maturation

MICROTUBULES are present in all eukaryotic cells and have been found to have a variety of structural and dynamic roles in cell shape, division, motility, transport and secretion[1]. In nervous tissue neurite outgrowth and axoplasmic transport are also thought to depend on microtubule integrity[2]. The microtubule subunit protein, tubulin, is a heterodimer composed of two polypeptides α and β (refs 3, 4). The α and β subunits show microheterogeneity and both have been resolved into two or three components[5–8]. The question therefore arises as to whether changes occur in the relative proportions of the multiple forms of tubulin upon assumption of different roles within the nerve cell. We show here that cytoplasmic rat brain tubulin, as resolved by isoelectric focusing, is highly heterogeneous. Moreover, tubulin microheterogeneity seems to be developmentally determined, increasing from seven to nine distinct components during early postnatal rat brain maturation.

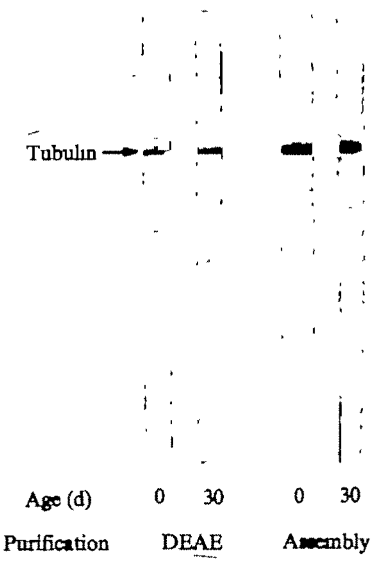

Fig. 1 SDS–polyacrylamide gel electropherogram of developing rat brain tubulin. Rat brain tubulin was prepared using DEAE-cellulose column chromatography following the procedure of Eipper[15] with slight modifications. Freshly obtained brains (2 g) from either newborn or 1-month-old rats were homogenised using a Dounce homogeniser, in 4 ml of 0.24 M sucrose, 2.5 mM $MgCl_2$ and 50 mM NaPPi, pH 7.0. The homogenate was centrifuged for 30 min at 30,000g and the supernatant obtained was loaded on to a DEAE-cellulose column (0.5×4 cm). After extensive washing with 0.1 M NaCl, 50 mM NaPPi, pH 7.0, and 2.5 mM $MgCl_2$, the tubulin peak was collected by elution with 0.26 M NaCl, 50 mM NaPPi, pH 7.0, and 2.5 mM $MgCl_2$, then dialysed against excess of H_2O and lyophylised. *In vitro* assembled tubulin was obtained by two cycles of polymerisation in the presence of 4 M glycerol as described by Shelanski *et al.*[16]. The purified tubulin preparations were dissolved in SDS sample buffer to yield a final concentration of 0.2 mg ml^{-1} protein, 10% glycerol, 5% 2-mercaptoethanol, 3% SDS, 0.0625 M Tris-HCl, pH 6.8, and 0.001% bromphenol blue and heated at 100 °C for 5 min. 10-µl aliquots were electrophoresed at 3 V cm^{-1} at 20 °C for 14–16 h on 0.75 mm thick polyacrylamide slab gels, containing 10–20% polyacrylamide gradient and 0.1% SDS[17,18]. The gels were stained with Coomassie brilliant blue.

However, extensive tubulin microheterogeneity is prominent in the brain, as tubulin from other organs is less heterogeneous.

Cytoplasmic tubulin from rat brain was identified by gel electrophoresis, its ability to undergo self-assembly, its purification by DEAE-cellulose column chromatography and

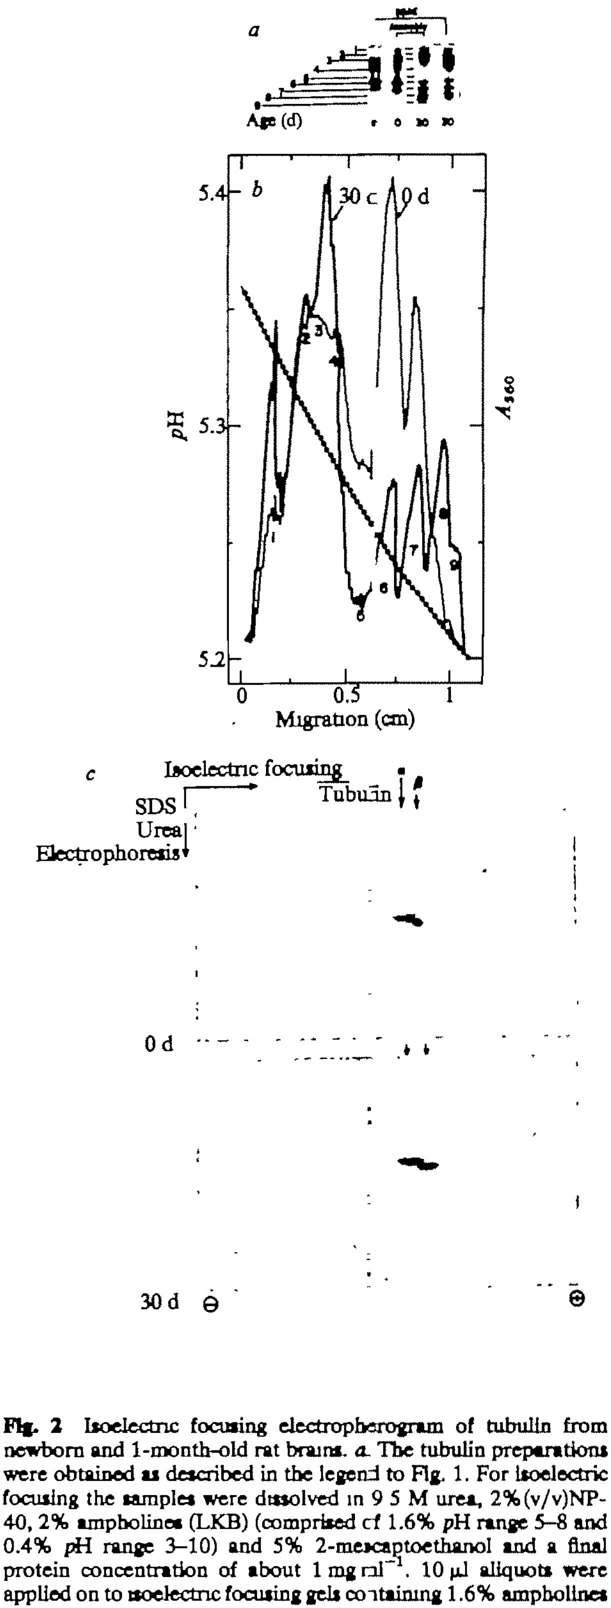

Fig. 2 Isoelectric focusing electropherogram of tubulin from newborn and 1-month-old rat brains. *a*. The tubulin preparations were obtained as described in the legend to Fig. 1. For isoelectric focusing the samples were dissolved in 9.5 M urea, 2%(v/v)NP-40, 2% ampholines (LKB) (comprised of 1.6% pH range 5–8 and 0.4% pH range 3–10) and 5% 2-mercaptoethanol and a final protein concentration of about 1 mg ml^{-1}. 10 µl aliquots were applied on to isoelectric focusing gels containing 1.6% ampholines in the pH range of 5–8 and 0.4% ampholines in the pH range of 3–10. Electrophoresis was carried out as described elsewhere[9]. On termination of the run, the gels were fixed for 60 min with 50% ethanol–7% acetic acid, soaked for 60 min with 20% methanol–7% acetic acid, stained for 5 min with 0.2% Coomassie brilliant blue–50% methanol–7% acetic acid and then destained with 20% methanol–7% acetic acid. *b*, Densitometric traces of the photographic transparencies of the isoelectric focusing gels of the DEAE-cellulose-purified tubulin were obtained by scanning at 560 nm in a Gilford 2400S spectrophotometer with a Gilford scanning attachment. The pH gradient was determined on termination of the electrophoresis (0). *c*, The DEAE-cellulose-purified tubulin separated by isoelectric focusing was subjected to 0.1% SDS–8 M urea–8.75% PAGE on a second dimension[9].

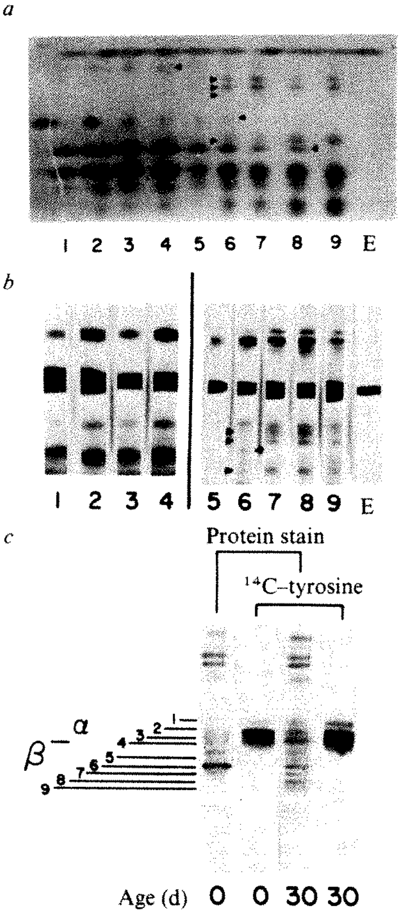

Fig. 3 Characterisation of the multiple tubulin species. *a*, *S. aureus* protease cleavage peptides of DEAE–cellulose-purified tubulin analysed on 15% polyacrylamide gel. The multiple tubulin species from 30-d-old rat brain were characterised by digestion with *S. aureus* v8 protease (36-900-1, Miles). The peptide analysis was carried out on a 15% polyacrylamide slab gel containing 0.1% SDS[19]. Tubulin bands were excised from the stained isoelectric focusing gels and soaked for 30 min in buffer containing 0.125 M Tris-HCl, *p*H 6.8, 0.1% SDS and 1 mM EDTA. The gel slices were inserted into sample slots of 15% polyacrylamide slabs with a 4-cm high upper gel. The slots were then filled with 10 μl of this buffer containing 20% glycerol and 0.001% bromphenol blue. Finally, 10 μl of the same buffer was added containing 10% glycerol and 750 ng of *S. aureus* protease. Constant voltage of 100 V was applied so that the tracking dye took 1.5 h to reach the bottom of the upper gel. The electrophoresis was then stopped for 60 min and resumed at 125 V at 10 °C and terminated 60 min after the tracking dye left the bottom of the gel. The arrow heads indicate differences in specific peptides. The isotubulins are marked in numbers according to their migration on isoelectric focusing gels. E = enzyme alone. *b*, Chymotrypsin cleavage peptides of DEAE–cellulose-purified tubulin as analysed on 15% polyacrylamide gel. The multiple tubulin species from 30-d-old rat brains were characterised by digestion with chymotrypsin (CDI-1450, Worthington). The peptide mapping was done as described above with the following modifications: 20 μg chymotrypsin were applied in each slot and the electrophoresis was stopped for 45 min instead of 60 min. The arrow heads indicate differences in specific peptides. The upper band was not marked, as its quantity varied in different experiments. The isotubulins are marked in numbers according to their migration on isoelectric focusing gels. E = enzyme alone. *c*, Tyrosylation of tubulin. Newborn and 30-d-old rat brain extracts were incubated for 10 min in the presence of L-[U-^{14}C]tyrosine (50 μCi μmol^{-1}, Radiochemical Centre), as described elsewhere[11]. The samples were diluted in 9.5 M urea, 2% (v/v) NP-40 and 2% ampholine comprised of 1.6% *p*H range 5–8 and 0.4% *p*H range 3–10 and 5% 2-mercaptoethanol. 50 μl aliquots of the suspension (final concentration ~1 mg ml^{-1}) were analysed by isoelectric focusing as described in Fig. 2, followed by autoradiography of the dried gels using X-ray film (Kodak RP-54). Note that the crude homogenate from newborn rat brain contained small amounts of band 8 which was not apparent when purified tubulin was subjected to isoelectric focusing.

by vinblastine precipitation. Purified rat brain tubulin showed only one major band of about 55,000 molecular weight on electrophoresis on SDS–polyacrylamide gels (Fig. 1). In contrast, several polypeptide chains could be resolved by isoelectric focusing. Figure 2*a*, *b* shows that tubulin obtained from newborn rat brain cytoplasm was resolved into seven bands, whereas that obtained from 30-d-old rat brain displayed nine bands. It should be noted that in both cases the resolution of bands 2, 3 and 4 was less pronounced than that of the other bands. Depending on the method of purification the relative proportion of the bands varied. Thus, bands 5 and 9 were more prominent with tubulin isolated by self-assembly, than with tubulin purified by DEAE–cellulose chromatography. However, the age-dependent increase in tubulin microheterogeneity was independent of the method of purification used. The absence of bands 8 and 9 from the young rat brain tubulin did not result from an instability factor manifesting itself during homogenisation. This was shown by purifying tubulin by DEAE–cellulose chromatography, from a 1 : 1 mixture of brain from newborn and 1-month-old rats. The purified material showed bands 8 and 9 in the proportions expected from such a mixture. Moreover, isolation of tubulin in the presence of protease inhibitors such as 0.4 mM phenylmethylsulphonyl fluoride, or a mixture of 40 μg ml^{-1} leupeptin, 20 μg ml^{-1} pepstatin A and 1 mg ml^{-1} bacitracin, did not change the pattern, indicating that the microheterogeneity does not arise from artefactual proteolysis (see also below). When the ampholine polyacrylamide gels were subjected to 0.1% SDS–8 M urea–8.75% polyacrylamide gel electrophoresis (PAGE) on a second dimension[9], bands 1, 2, 3 and 4 were found to correspond to the α-tubulin subunit and bands 5, 6, 7, 8 and 9 to the β subunit[10] (Fig. 2*c*). Thus, isoelectric focusing did not alter the tubulin mobility on electrophoresis on urea–SDS–polyacrylamide gels.

The relationship of the various tubulin bands was examined by protease digestion. After isoelectric focusing of tubulin extracted from 30-d-old rat brain the different bands were excised, subjected to *Staphylococcus aureus* protease or chymotrypsin digestion and analysed by SDS–PAGE. The results in Fig. 3*a*, *b* show a close similarity in the overall distribution of the polypeptide chains derived from each preparation, indicating a structural homology between the isotubulins and eliminating the possibility of non-tubulin contaminants. The distribution pattern of the cleavage peptides was independent of the proteolytic enzyme concentration. Moreover, comparison of the peptide maps of tubulin with non-related proteins such as actin showed marked differences (data not shown). Closer examination of the peptide maps (Fig. 3*a*, *b*) reveals differences between bands 1–5 and 6–9. In addition, band 9 differs from bands 6–8 (Fig. 3*a*) and band 6 differs from bands 7–9 (Fig. 3*b*). Although band 5 closely resembles bands 1–4 (α-tubulin), it migrates as β-tubulin when resolved by two-dimensional electrophoresis[10]. Band 5 also differs from bands 1–4 in its inability to undergo *in vitro* tyrosylation (Fig. 3*c*); this reaction is characteristic of the α-tubulin subunit[11]. All the above results suggest the existence in adult rat brain of multiple non-identical tubulin species exhibiting different isoelectric points, but similar molecular weights.

Extensive tubulin microheterogeneity seems to be prominent in the brain, as tubulin from other tissues such as 30-d-old rat liver and spleen as well as neuroblastoma–glioma NG108-15 hybrid cells were less heterogeneous and contained two major subunits (Fig. 4*a*, *b*). Peptide map analysis showed that the two tubulin species were similar to the corresponding isotubulins of rat brain, indicating no major contamination in this preparation (data not shown). The pronounced microheterogeneity of rat brain tubulin is not due to specific proteolytic cleavage occurring during the homogenisation and isolation procedures. This was shown by purifying tubulin from a mixture of ^{35}S-methionine-labelled neuroblastoma–glioma hybrid cells in the presence of 30-d-old rat brain. Figure 4*b* shows that such a mixing experiment did not produce additional radioactive isotubulins. In

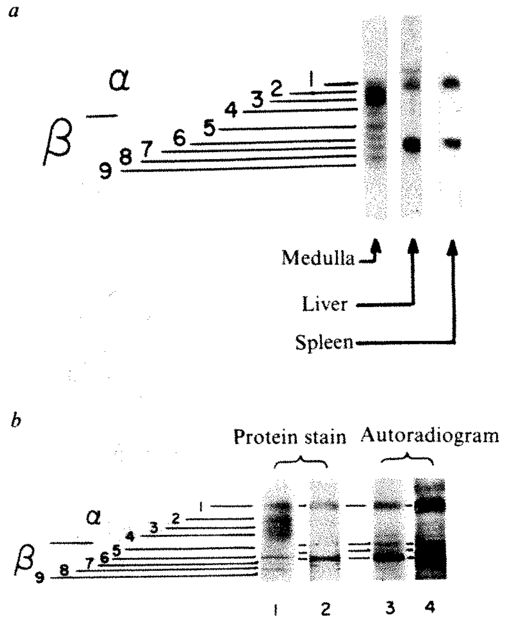

Fig. 4 Multiple forms of tubulin in various tissues. *a*, Isoelectric focusing of 30-d-old rat tubulin prepared from medulla oblongata, liver and spleen. Tubulin was purified by precipitation with vinblastine (Lilly). The various tissues were homogenised in 2 volumes of 0.25 M sucrose, 10 mM phosphate buffer, *p*H 7.4, 10 mM $MgCl_2$ and 0.2 mM GTP, and the supernatants (1 mg protein ml^{-1}) obtained after 1 h centrifugation at 105,000*g* were subjected to vinblastine (1 mg ml^{-1}) precipitation[18]. The precipitated proteins were dissolved in 9.5 M urea, 2%(v/v)NP-40, 2% ampholines (comprising 1.6% *p*H range 5–8 and 0.4% *p*H range 3–10) and 5% 2-mercaptoethanol, and a final protein concentration of ~1 mg ml^{-1}. 10 μl aliquots were applied on to isoelectric focusing gels containing 1.6% ampholines in the *p*H range of 5–8 and 0.4% ampholines in the *p*H range of 3–10. The gels were stained with Coomassie brilliant blue (as described in the legend to Fig. 2). *b*, Isoelectric focusing of tubulin from neuroblastoma–glioma hybrid cells prepared in the presence of 30-d-old rat brains. Neuroblastoma–glioma hybrid cells (NG108-15) grown as described elsewhere[20] were incubated for 24 h in the presence of ^{35}S-methionine (700 Ci $mmol^{-1}$, Radiochemical Centre), 100 μCi per 10-cm diameter plates containing 10 ml medium. The packed cells (100 μl of a pellet centrifuged at 1,000*g* for 5 min) were homogenised in 200 μl of 0.25 M sucrose, 10 mM phosphate buffer, *p*H 7.4, 10 mM $MgCl_2$ and 0.2 mM GTP, in one experiment. In a second experiment 100 μl of packed labelled cells were mixed with 0.1 g of 30-d-old rat brain and homogenised in 400 μl of the above buffer. The 105,000*g* supernatants obtained after 60 min centrifugation were subjected to vinblastine precipitation[18]. The vinblastine pellets were analysed by isoelectric focusing followed by autoradiography (as described in the legends to Figs 2, 3). 1, Tubulin prepared from a mixture of hybrid cells and brains stained with Coomassie brilliant blue; 2, tubulin prepared from hybrid cells stained with Coomassie brilliant blue; 3, autoradiogram of tubulin from hybrid cells prepared in the presence of rat brain homogenate; 4, autoradiogram of tubulin isolated from hybrid cells.

addition, the limited tubulin microheterogeneity found in neuroblastoma–glioma hybrid cells is not the result of a specific protease inhibitor. As shown in Fig. 4*b*, there was no reduction in the multiple species of brain tubulin isolated in the presence of neuroblastoma–glioma hybrid cells (Coomassie brilliant blue-stained bands).

In conclusion, an increase in the tubulin microheterogeneity was demonstrated during brain maturation. This process coincides with an increase in the ability of tubulin to undergo self-assembly[12–14], suggesting that the changes in the multiple tubulin forms control microtubule formation.

We thank Mr M. D. Walker and Dr J. Prives for discussions, Mrs C. Kalcheim for help in the tyrosylation experiment and Mrs A. Zutra for the neuroblastoma–glioma cells. This work was supported in part by grants (to U.Z.L) from the US-Israel Binational Science Foundation (BSF), Jerusalem.

Fibroblasts degrade newly synthesised collagen within the cell before secretion

COLLAGEN, the major extracellular protein of most tissues, is considered a relatively inert macromolecule, with a turnover rate slower than that of most proteins[1]. There is, however, a portion of the total collagen pool that is rapidly turning over, for tracer studies of collagen metabolism in intact animals have demonstrated that a significant amount of newly synthesised collagen is apparently degraded within hours of its synthesis[2]. Further, direct evidence for the rapid degradation of collagen has been provided by studies of rabbit lung explants which showed that 30–40% of newly synthesised collagen was degraded within minutes of its synthesis[3]. This phenomenon is of interest because it involves such a large proportion of collagen production, and thus may significantly influence the quantity of collagen within a tissue and hence organ structure and function. The time course of this rapid degradation of collagen suggests that it occurs within the collagen-producing cells before its secretion. Although it has been repeatedly demonstrated that intracellular degradative processes have a central role in regulating the quantity of proteins that function within cells, intracellular degradation has not been considered a general mechanism for regulating the quantity of proteins destined for extracellular function[4–6]. We describe here a direct evaluation of the hypothesis that extracellular levels of collagen are regulated, in part, by the rapid degradation of newly synthesised collagen before it reaches the extracellular space. We have studied the size and kinetics of collagen production by fibroblasts in culture, and have found that not only is a significant proportion of newly synthesised collagen degraded intracellularly, but also that the process can be modulated by manipulating the structure of the collagen molecule.

All studies used subcultivations 10–20 of a human fetal lung fibroblast termed HFL-1; this cell strain is diploid, free of

0028–0836/78/0276—0413$01.00

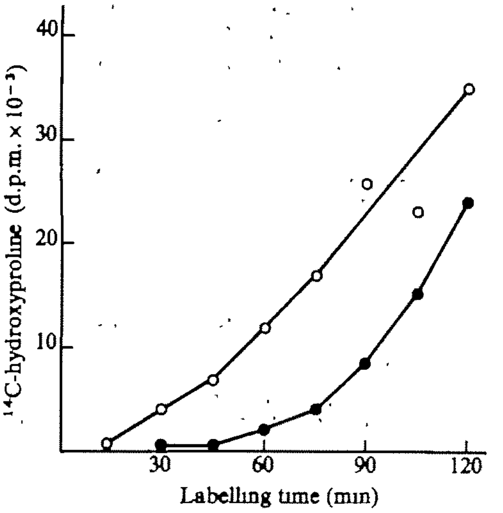

Fig. 1 Time course of the synthesis and secretion of collagen by HFL-1 fibroblasts. Collagen is represented as the quantity of ^{14}C-hydroxyproline found in the cell layer (○) or media (●) at various times following addition of ^{14}C-proline to the cultures. Cells were plated at 10^6 cells per 150-mm culture dish and maintained at 37°C (10% CO$_2$ in air) in 20 ml growth medium (Dulbecco's modified Eagle's medium (DMEM) with added fetal calf serum (10%), glutamine (0.06%), penicillin (100 U ml^{-1}) and streptomycin (100 μg ml^{-1})) which was changed every 3 d. All studies of collagen production were done after the cells had reached the stationary phase (usually 7–8 d after subcultivation) 24 h before labelling, ascorbic acid (50 μg ml^{-1}) was added to the growth medium. To evaluate collagen production by HFL-1 fibroblasts, the cells were washed (×3) with phosphate-buffered saline (PBS) *p*H 7.4, and incubated with growth medium supplemented with ascorbic acid (50 μg ml^{-1}) and *β*-aminopropionitrile (50 μg ml^{-1}). After 1 h, the supplemented growth medium was discarded and replaced with 10 ml of labelling medium (DMEM, dialysed fetal calf serum (10%), glutamine (0.06%), penicillin (100 U ml^{-1}), streptomycin (100 μg ml^{-1}), ascorbic acid (50 μg ml^{-1}), *β*-aminopropionitrile (50 μg ml)$^{-1}$ and ^{14}C-proline (10 μCi ml^{-1}, 260 mCi mmol^{-1}, Schwarz-Mann)). The dialysed fetal calf serum used in the labelling medium was prepared by dialysing fetal calf serum against PBS so as to remove amino acids that would dilute the tracer but to retain antiproteases. At each time point indicated, culture plates were removed from the incubator, placed on ice, and the culture medium collected. The cell layer was washed with PBS (×3) and the washings combined with the medium. The cell layers were scraped from the plate using 20 ml 0.5 M acetic acid. The media and cell layer samples were sonicated, heated at 100°C for 10 min to inactivate proteases, and aliquots taken for quantitation of ^{14}C-hydroxyproline using acid hydrolysis (6M HCl, 110°C, 20 h) and ion-exchange chromatography as previously described[3]. The values for ^{14}C-hydroxyproline represent the total disintegration per min (d.p.m.) of ^{14}C-hydroxyproline found in the cells or medium for each plate independent of whether the collagen was intact or degraded. The total number of cells per plate varied by less than 5%.

mycoplasma and viral infection, and exhibits contact inhibition[7]. HFL-1 synthesises both collagen types I and III, which together represent 3–5% of the total proteins synthesised by this cell. Degradation of newly synthesised collagen in HFL-1 was followed by labelling the cells, in the presence of fetal calf serum, with either ^{14}C-proline or ^{14}C-lysine and quantitating the proportion of newly synthesised proteins containing ^{14}C-hydroxyproline or ^{14}C-hydroxylysine that could pass through a dialysis membrane[3]. This experimental design for quantitating collagen degradation was based on the fact that in cultures of human fibroblasts, labelled hydroxyproline and hydroxylysine can be used as specific markers for newly synthesised collagen. Although both amino acids are found in Clq, a complement component also synthesised by the fibroblast, estimates of the relative synthetic rates for Clq and collagen demonstrate that the Clq is synthesised at 0.1% the rate (per fibroblast) of collagen[8].

As expected for a protein destined for extracellular function, newly synthesised collagen was detected in the cell layer of the HFL-1 cultures 15–30 min before its appearance in the culture medium (Fig. 1). The time course for collagen synthesis and secretion found in these cells is comparable to that of other vertebrate mesenchymal cells[9].

Strikingly, 30 min after the addition of the tracer, even though the newly synthesised collagen had not then been secreted (Fig. 1), approximately 30% of the labelled collagen in the cell layer was already degraded to peptides small enough to pass through a dialysis membrane (Fig. 2). One hour after the addition of the tracer, degraded collagen was detected in both the cell layer and the medium, but the combined total of degraded collagen represented a constant fraction of the total amount of collagen synthesised during the labelling period. Even 24 h after addition of the tracer to the cultures, the same fraction of newly synthesised collagen was found to be degraded, although by this

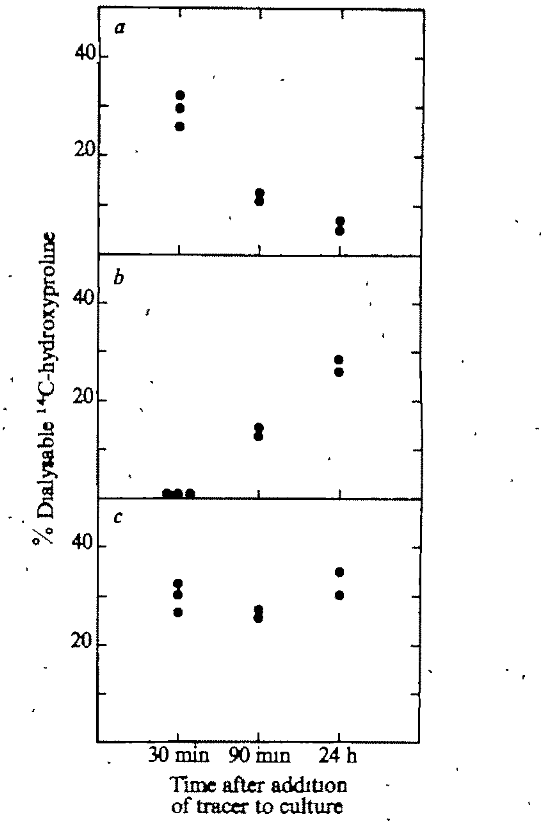

Fig. 2 Proportion of newly synthesised collagen degraded by HFL-1 cells. Cells were maintained in culture and labelled with ^{14}C-proline as described in Fig. 1. After a 30-min labelling period, the labelling medium was discarded, the cell layers were washed three times with PBS, and 20 ml of 'chase' medium (identical to labelling medium except that 1 mM unlabelled proline was substituted for ^{14}C-proline) was added. At 0, 1 or 23.5 h after addition of the chase medium (representing respectively, 30 min, 90 min or 24 h after the tracer had been originally added to the culture), the incubation was stopped and the media and cell layer collected separately as described in Fig. 1. Following sonication and heating, an aliquot was taken for analysis of ^{14}C-hydroxyproline in the *a*, cell layer, *b*, media or *c*, cell layer and media that was dialysable[3]. Per cent dialysable ^{14}C-hydroxyproline was calculated from the formula: % dialysable ^{14}C-hydroxyproline = [(d.p.m. of total ^{14}C-hydroxyproline in the sample) − (d.p.m. of ^{14}C-hydroxyproline in the sample after dialysis)] × 100/[d.p.m. of total ^{14}C-hydroxyproline in the sample]. 30 min after addition of ^{14}C-proline to the culture (that is, 9 h chase time), an average of 30% of ^{14}C-hydroxyproline in the culture was dialysable, and all was present in the cell layer. With time after the chase, the proportion of dialysable ^{14}C-hydroxyproline in the cell layer decreased and the proportion of dialysable ^{14}C-hydroxyproline in the media increased. Even so, the proportion of the total ^{14}C-hydroxyproline in the culture (cell layer and media) that was dialysable remained constant (*c*, $P > 0.1$, Student's two-tailed *t*-test).

time most of the degraded peptides had moved from the cell layer to the culture medium. Evaluation of the size distribution of the peptides derived from degraded collagen demonstrated that more than 90% of the degraded collagen was reduced to less than 500 daltons within 6 h (data not shown). Thus, not only do these cells rapidly metabolise a significant proportion of newly synthesised collagen, but they also degrade these macromolecules to very small fragments. However, a proportion of the degraded collagen was still in peptide linkage, for chromatography of the dialysable material on the amino acid analyser before acid hydrolysis resulted in a significant reduction in the ^{14}C-hydroxyproline recovered (R. Berg and R. G. C., unpublished observations). This, and the fact that the proportion of dialysable ^{14}C-hydroxyproline did not increase with time of culture (Fig. 2), are consistent with the overwhelming evidence that any hydroxyproline found in these cultures is derived from proline residues in peptide linkage (rather than an ester link such as that found in prolyl-tRNA)[10–13].

When HFL-1 cells were labelled with ^{14}C-lysine in the same conditions as with ^{14}C-proline, approximately 22% of the labelled ^{14}C-hydroxylysine was found in peptides small enough to pass through a dialysis membrane (Fig. 3). This observation is important because hydroxyproline (but not hydroxylysine) residues are present in the N-terminal ('Pn') precursor piece of collagen pro α1(I) chains (D. Hörlen and P. Fietzek, personal communication), and the finding of ^{14}C-hydroxylysine in dialysable peptides indicates that the material being degraded in these cultures includes the α-chain portion of newly synthesised collagen[3].

The fact that the degraded collagen was detected in the cell layer before the time required for HFL-1 cells to synthesise and secrete collagen argues strongly that this degradative process was occurring within, and not outside, the cells. Other evidence supports this conclusion. First, at the time degraded collagen was detected in the cell layer (Fig. 2*a*) none was found in the media (Fig. 2*b*). Although it is conceivable that collagen was degraded outside the cells and the resulting fragments then internalised, the time course of collagen degradation argues against this. Second, when purified ^{14}C-labelled human type I procollagen was incubated with HFL-1 cultures for 6 h, 100% of the labelled procollagen could be recovered intact, suggesting that the culture media did not contain active proteases capable of degrading collagen (data not shown). However, to ensure that any putative extracellular collagen-specific proteases would be inhibited, all experiments were carried out in the presence of 10% fetal calf serum, a concentration sufficient for the complete inhibition of mammalian collagenase capable of digesting 12 µg of collagen per h at 37°C (ref. 14). In addition, even in the absence of the fetal calf serum, no active collagenase could be detected in the culture media of HFL-1 fibroblasts incubated for 24 h.

Third, when the cells were pulsed with ^{14}C-proline for 30 min and then chased with unlabelled proline, the proportion of labelled collagen degraded did not change even when the cultures were continued for 24 h. If degradation was due to proteolytic enzymes outside the cells, it is likely that a progressive increase in collagen degradation would have been noted as the culture continued. The time invariance of the proportion of total collagen degraded in the pulse–chase experiments also suggested that the dialysable collagen peptides found in these cultures represented active degradation rather than simply uncompleted collagen chains 'nascent' on polyribosomes at the end of the pulse period. If it was the latter, these should have been completed during the 'chase' and the proportion of dialysable ^{14}C-hydroxyproline would have decreased.

Thus, it is apparent that a large proportion of collagen produced by diploid human fibroblasts is degraded rapidly within the cells. As this degradative process occurs before the time necessary for secretion, and as the proportion of collagen that is degraded does not change with time, it is likely that this phenomenon occurs before secretion and not after a process of secretion and phagocytosis. If the latter were responsible, the time required would be much longer and the labelled collagen in the cultures would be progressively destroyed as the culture times were extended. It is not certain, however, that all the dialysable ^{14}C-hydroxyproline and ^{14}C-hydroxylysine found in these cultures were necessarily derived from intact collagen chains. If, for example, there was premature termination of some of the collagen being synthesised, these incomplete chains might be more susceptible to degradation than fully completed pro α chains.

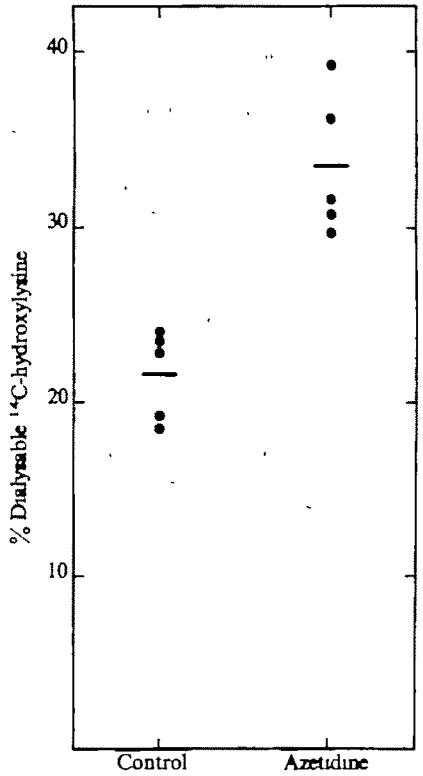

Fig. 3 Influence of azetidine-2-carboxylic acid (azetidine) on the degradation of newly synthesised collagen by HFL-1 cells. HFL-1 cells were maintained in culture as described in Fig. 1. To evaluate collagen production in the presence of azetidine, the cells were first washed three times with PBS and incubated with lysine-free DMEM supplemented with ascorbic acid (50 µg ml^{-1}) and β-aminopropionitrile (50 µg ml^{-1}). After 1 h, the supplemented growth medium was discarded and replaced with labelling medium (lysine-free DMEM, dialysed fetal calf serum (10%), glutamine (0.06%), penicillin (100 U ml^{-1}), streptomycin (100 µg ml^{-1}), ascorbic acid (50 µg ml^{-1}), β-aminoproprionitrile (50 µg ml^{-1}) and ^{14}C-lysine (10 µCi ml^{-1}, 300 mCi mmol^{-1}, Schwarz-Mann)), to which either proline (100 µg ml^{-1}, Schwarz-Mann) or azetidine (100 µg ml^{-1}, Calbiochem) had been added. Following incubation for 12 h, the cell layers and culture media were combined, sonicated and heated at 100°C for 10 min. An aliquot was taken for the measurement of total ^{14}C-hydroxylysine in the sample and the remainder dialysed against 0 5 M acetic acid and 0.1 mM hydroxylysine The proportion of newly synthesised collagen (represented by ^{14}C-hydroxylysine) that was degraded was quantitated as follows. % dialysable ^{14}C-hydroxylysine = [(d.p m. of total ^{14}C-hydroxylysine in the sample) − (d.p.m. of ^{14}C-hydroxylysine in the sample after dialysis)] × 100/[d.p.m. of total ^{14}C-hydroxylysine in the sample]. Each experimental point represents the per cent dialysable ^{14}C-hydroxylysine observed for separate culture plates The control plates (cells labelled with ^{14}C-lysine in the presence of proline) averaged 22 ± 3% and the azetidine plates (cells labelled with ^{14}C-lysine in the presence of azetidine instead of proline) averaged 33 ± 5%, the values were significantly different at the $P < 0.01$ level (Student's two-tailed t-test).

If intracellular collagen degradation is an important post-translational mechanism which modulates the differentiated state of fibroblasts with respect to collagen production, these cells should have means available to vary the relative proportion of newly synthesised collagen that is degraded by this process.

There is accumulating evidence that intracellular degradative processes can recognise and destroy protein with abnormal conformations[4], so that one way to evaluate whether cells can alter intracellular collagen degradation is to manipulate the cells to produce collagen molecules with an abnormal structure. The approach used was to incubate HFL-1 cells in medium in which azetidine-2-carboxylic acid had been substituted for proline. Azetidine, the lower homologue of proline, is readily taken up by cells, recognised by prolyl-tRNA, and incorporated into newly synthesised collagen in place of proline[15]. However, the presence of the azetidine ring in the collagen polypeptide chain precludes normal helix formation[16,17]. Interestingly, when this was done, intracellular collagen degradation increased almost twofold (Fig. 3). Thus, cells seem to have means by which they can modulate the fraction of total collagen that is degraded within the cell before secretion.

As might be expected for a macromolecule with such a critical role in organ structure and function, there seem to be several ways in which the metabolism of collagen can be regulated. For collagen already outside the cell, extracellular proteases such as collagenase are undoubtedly paramount in this regard[18]. The present study suggests that mechanisms are also available by which cells can degrade a significant, yet adjustable, proportion of newly synthesised collagen before it ever reaches the extracellular space. Further study will be required to ascertain whether this is a general control phenomenon for secreted proteins or whether it is unique to collagen.

Nitrogen fixation in the rhizosphere of rice

THE discovery of nitrogen-fixing activity associated with the rhizosphere of non-leguminous plants such as tropical grasses, rice and maize has provoked considerable interest[1–9]. Discrepancies in the measurements of this nitrogen-fixing activity by the acetylene reduction assay in different conditions prompted us to develop a modified assay system. We report here the use of this assay to find significant differences in the rates of acetylene reduction associated with the rhizosphere of 50 different strains of rice. This suggests that the rice plant genotype influences the association with nitrogen-fixing bacteria in its rhizosphere.

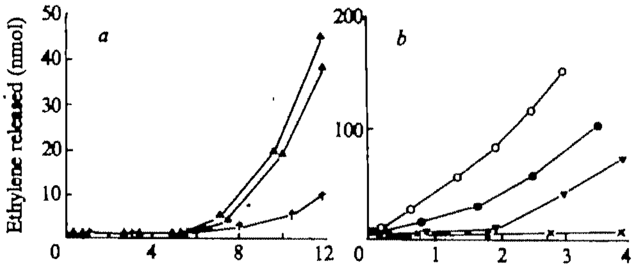

Fig. 1. Time course of C_2H_2-reducing activity in different assay conditions. C_2H_2-reducing activity was measured by gas chromatography (Shimadzu GC-3BF) with H_2-flame ionisation detector. Assay conditions were a 2-cm column containing Porapack Q of 80–100 mesh with N_2 gas as carrier at a flow-rate of 40 cm³ min^{-1} at 80 °C. *a*, The gas phase was replaced with a mixture of 0.1 atm C_2H_2 and 0.9 atm He and incubated at 30 °C until assayed. (▲), Excised roots washed with tap water and kept in a flask, per g dry root; (△), whole plant with soil kept in a polyethylene bag, per g dry root; (+), soil alone kept in a flask, per 100 g. *b*, Whole plant kept in a vessel containing different gas phase (per g dry root). Gas phase: 0.1 C_2H_2 and 0.9 He (○); 0.1 C_2H_2 and 0.9 air (●); and after the gas phase was replaced with 1 atm air and kept for 30 min in order to expose rhizosphere to air, it was replaced again with a mixture of 0.1 C_2H_2 and 0.9 He (▼). Control, no C_2H_2 (×).

The first report of high levels of nitrogen-fixing activity associated with isolated roots of maize was by von Bülow and Döbereiner[4]. Subsequently, using the maize–*Spirillum lipoferum* system, Burris *et al.*[10] showed that the acetylene-reducing activity of intact plants or soil cores containing the bulk of a relatively undisturbed root system was far less than that of preincubated roots. Similar observations were made in rice. When the excised root system or intact plant kept in a polyethylene bag was preincubated under either aerobic or anaerobic conditions, the activity remained almost zero for the first few hours after incubation[8,11–13] and increased exponentially on further incubation. In the maize–*Spirillum* system, a marked proliferation of the bacteria during preincubation was observed[14,15]. This suggested that the activity detected after a lag period might be due to the increased number of bacteria and might not represent the activity in the intact plant.

We devised the following assay system with these observations in mind. An intact plant including the soil and water of the rice rhizosphere and the bulk of the relatively undisturbed root system was enclosed in a vessel such as a desiccator so that the exposure of the rhizosphere to air was minimised. Rigorous displacement of the gas phase in the vessel with a mixture of helium and acetylene (9:1 by volume) was achieved two times by an evacuation pump (up to 0.02 atm) and flushing the gas mixture up to 1 atm. The vessel was flushed with the gas mixture for 30 min to equilibrate the system, evacuated and flushed again. The system was incubated in normal laboratory light at 28 °C and fractions of the gas phase were withdrawn with a syringe for assay. The ethylene produced from acetylene was measured by gas chromatography[16,17]. It was thought that the assay procedure enabled us to displace the air remaining in the assay sample with the gas mixture containing acetylene as a substrate so that the substrate could effectively reach the inner part of the sample where nitrogen fixation was active without disturbing the rhizosphere. The observations described below suggest that the above two assay conditions must be fulfilled to measure the nitrogen-fixing activity in rhizosphere correctly.

Figure 1 shows the kinetics of acetylene reduction in the rice rhizosphere measured in the various assay conditions. When the assay system described above was used, considerable acetylene reduction activity was found with certain strains of rice. The production of ethylene from acetylene was linear and no time lag in the reaction was observed. The activity detected by this method was found in conditions in which almost no time was allowed for bacterial growth in the system. On the other hand,

0028-0836/78/0276—0416$01 00

the other assay system using polyethylene bags[13] or excised roots in a flask[4,12] showed a distinct time lag before ethylene production was detected. When acetylene was not added to the system, no ethylene was produced. Soil without plants showed no detectable acetylene reducing activity during a 6-h incubation and later small but significant amounts of ethylene were observed. Aerobic conditions for acetylene reduction gave lower activity than anaerobic conditions. Exposure of the rhizosphere to the air for 30 min also reduced activity considerably. Plants were incubated in the light and it is possible that photo-produced oxygen is altering the physiological environment of the rhizosphere to favour microaerophilic bacteria. This, however, is unlikely as our whole plant assay system showed linear acetylene reduction without a lag. From this we deduce that our assay system measures functional nitrogenase activity in the rhizosphere and provides a useful method to assay the nitrogen-fixing activity of the plant–rhizosphere complex.

The nitrogen-fixing activity of the rhizosphere of 50 strains of rice was then measured. The strains used were collected from various parts of tropical Asia and preserved at the Genetic Stocks Centre, National Institute of Genetics, Mishima. The plants were grown in pots until they flowered and the activity of these intact plants, two of each strain, was then measured in our assay conditions. Measurements were taken 1 and 2 h after incubation and the amount of ethylene produced per hour per plant was calculated. The values obtained early after incubation reflected the activity of the rhizosphere as then any activity caused by the growth of nitrogen-fixing bacteria could be ruled out. The rate of nitrogen fixation varied widely between strains (Table 1). In addition, 20 pots containing soil without plants were measured as controls. No activity was detected in these pots during the first few hours of incubation at room temperature. Results shown in Table 1 were measured within 2 h of incubation. There was, therefore, a distinct difference in the nitrogen-fixing activities between controls and experimental pots. The variation among strains was statistically significant (Table 2). Activity expressed per g dry root per hour also showed a wide range of significant variation between strains. The highest value was about 1,100 nmol per plant per hour. Strains showing high activity were collected in India and Thailand. However, the value was rather low compared with those (2,000–6,000 nmol per g dry root per h) obtained by Dommergues *et al.*[9] using rice strain IR 8. Also using IR 8, Lee *et al.*[13] reported lower values (1,870 nmol per pot per h). Because the soil used in those experiments and experiments reported here might have contained different microbial floras and the activity was also measured in different assay conditions, it is difficult to compare these results.

There was a correlation ($r = 0.895$, significant at the 1% level) between root weight and nitrogen-fixing activity within a strain. This means the larger the amount of root per unit area, the higher the activity. Roots are, therefore, apparently essential for bacterial nitrogen fixation in the paddy field.

Seeds of a rice strain associated with high nitrogen-fixing activity were sterilised and grown in sterilised soil under germ-free conditions. Nitrogen fixation was measured. No acetylene reduction was detectable on the sterile plant, suggesting that microorganisms must be involved. Although no nodules were found on the roots of rice associated with high nitrogen-fixing activity, an anaerobic, rod-shaped, Gram-positive, biotin-requiring bacterium, which formed terminal spores was isolated. This is thought to be a *Clostridium*. It is known, however, that from a single soil sample one can isolate many species of bacterium capable of fixing nitrogen, such as *Desulfovibrio*, *Mycobacterium* and *Beijerinckia*, and it is not yet possible to detect which bacterium is responsible for nitrogen fixation in the rice rhizosphere. A systematic examination of nitrogen-fixing bacteria in the rhizosphere of rice in our experimental field is in progress.

Table 1 Variation in acetylene reducing activity of 50 rice strains

C_2H_2 produced (nmol per plant per h)	No. of strains
0–200	13
200–400	23
400–600	8
600–800	2
800–1,000	3
1,000–1,200	1

Acetylene reducing activity of strains was obtained by averaging the measurements of two plants obtained during the flowering period.

Table 2 Analysis of variance of acetylene reducing activity among 50 rice strains

Source of variation	d.f.	Sum of squares ($\times 10^{-3}$)	Mean square ($\times 10^{-3}$)
Total	99	8,152	
Strain	49	5,576	113.8*
Error	50	2,576	51.5

* Statistically significant at the 1% level.

The significant variation found among rice strains in their degree of association with nitrogen fixation could suggest that the genotype of the plant influences this association. A readily available source of energy is crucial in establishing the association of nitrogen-fixing microbes with rice. If the rice plant excretes available substrates through its root system, microorganisms would take advantage of this to grow and fix nitrogen in conditions which do not repress nitrogenase synthesis. Certain types of plant excrete sufficient carbohydrate to support a sizeable microbial population[3,18]. Not only *Azotobacter* and *Spirillum* benefit, but also strictly anaerobic organisms such as *Clostridium* and facultative organisms[19,20]. The significant correlation between the activity of nitrogen fixation and root weight as well as the genotype of the rice plant could be due to a dependence of nitrogen-fixing microbes on the energy source provided by the plant. As a great deal of energy is needed to support microbial growth and nitrogen fixation, the energy source will be the limiting factor for the plant–bacterium association.

We thank Professor John Postgate for critical comments on the manuscript and Dr K. Shimotohno for advice on gas chromatography and Dr K. Komagata for help with isolation and classification of a nitrogen-fixing bacterium. This study was supported by grant 111905 from the Ministry of Education, Japan.

Identification of a new chicken α-globin structural gene by complementary DNA cloning

THE identification of a new chicken α-globin gene is reported here. Nucleotide sequence analysis of clone pHb1003 shows it to code for an α-subunit with an amino acid sequence different from those normally observed in the adult (the αA and αD). Characterisation of a second clone, pHb1010, carrying the same novel sequence, suggests that this mRNA sequence was present in substantial quantity after very young (2–3-week-old) chickens were treated with phenylhydrazine. The results are therefore similar to those reported previously for sheep and goats, where treatment with phenylhydrazine results in the turn-on of a new stress globin gene. As the ease of obtaining nucleated erythrocytes from avian systems facilitates many types of biochemical studies, we believe that this finding may provide an especially useful system in which to study the molecular events involved in globin gene switching.

Our laboratory has previously reported the complementary DNA (cDNA) cloning of globin mRNA sequences from phenylhydrazine-treated 2–3-week-old white Leghorn chickens[1]. One of these clones, pHb1003, was shown by the ladder DNA sequencing technique of Maxam and Gilbert[2] to contain an α-globin cDNA insert. This determination was based on the discovery of a nucleotide sequence within a pHb1003 *Hae*III insert band which codes for amino acid residues 86–98 of the chicken αA primary structure as determined by Matsuda[3]. These amino acids are highly conserved in most vertebrate α-globin proteins[4]. As such, this sequence is useful for identifying pHb1003 as an α-globin insert, but it does not indicate whether this DNA is derived from the αA or another α gene. Other positions along the α-globin molecule are more variable, most notably positions 102–125, and 46–82 (ref. 4). Restriction mapping data (Fig. 1) enabled us to locate and sequence pHb1003 DNA fragments from the latter variable region. Using the ladder technique, sequences were obtained from a 510-base pair *Alu*I fragment coding for the untranslated region at the 5′ end of the mRNA and amino acids 1–83 of the α globin (Fig. 2). The 69-base pair sequence obtained codes for amino acid residues 60–83 of the α globin. It includes 10 positions where the amino acid sequence is not compatible with the αA sequence and 16 positions which diverge from the αD sequence[5] (Fig. 3). The presence of so many differences argues against the idea that we are observing an allelic form of either the αA or αD genes.

As the αA and αD subunits account for 70% and 30%, respectively, of the α-subunits normally present in adult chicken reticulocytes[6,7], this raises several interesting possibilities. The polypeptide coded by pHb1003 might represent a minor normal

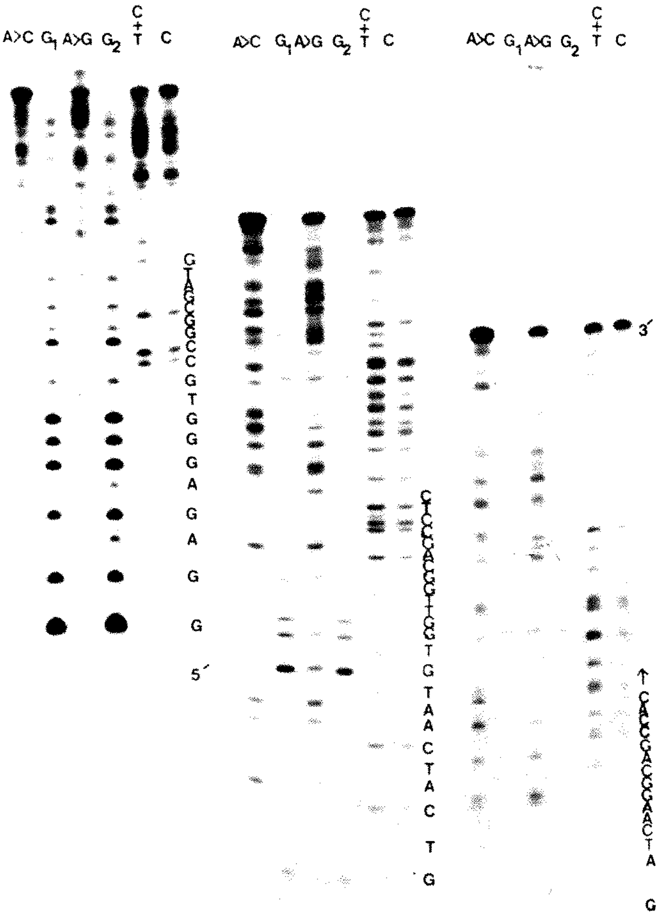

Fig. 2 Autoradiogram of the ladder sequence from a 480-base pair *Alu*I pHb1003 insert band. 100 μg of pHb1003 was digested with *Alu*I and the products were fractionated on a 6% acrylamide 1/28 bisacrylamide preparative gel. The 510-base pair insert fragment was eluted from the gel in high salt overnight. The 5′-terminal phosphates were removed by treatment with bacterial alkaline phosphatase and replaced with the ^{32}P label of λ ^{32}P-ATP using T4 polynucleotide kinase. This DNA, which was labelled at both 5′ termini, was cleaved with *Hae*III, giving two single-end-labelled fragments of 320 and 190 base pairs. The 190-base pair DNA was aliquoted into 5 equal fractions. The aliquots were separately subjected to partial chemical cleavages specific for G, A, A>C, C+T and C. The partial cleavage products were then loaded side by side on 20% acrylamide 1/60 bisacrylamide 7 M urea gels at 3 successive intervals. The radioactive bands were visualised by autoradiography at −70 °C with Kodak Hi-Plus tungstate intensification screens. The nucleotide sequence is read from the 5′ end at the bottom of the gel to the 3′ end at the top. The sequence shown is complementary to the pHb1003 coding strand.

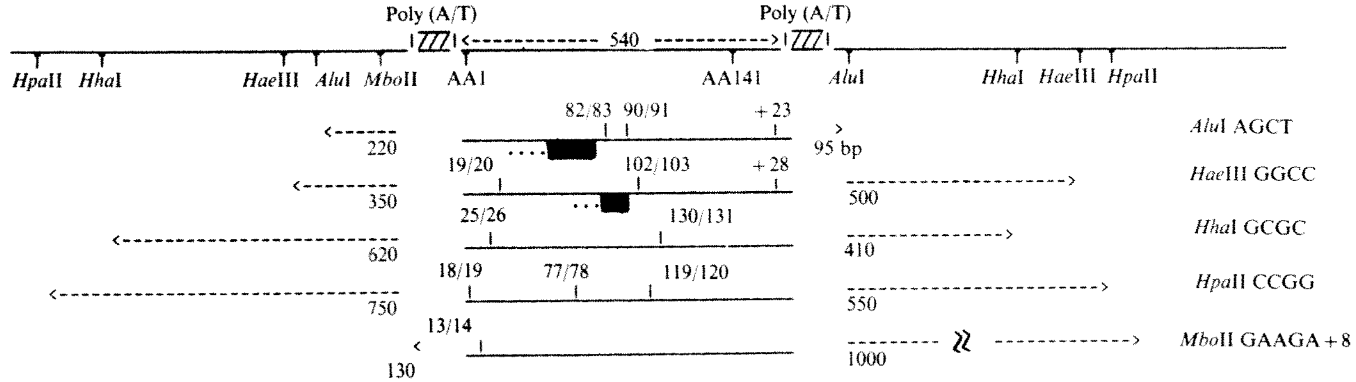

Fig. 1 Restriction map of the pHb1003 α-globin cDNA insert. Insert fragments were identified and sized by electrophoresis of various pHb1003 restriction digests alongside similar cleavages of the pMB9 vector on 6% acrylamide 1/29 bisacrylamide gels. Secondary digests of purified insert cleavages occurring within the 3′ untranslated region are denoted by a '+' followed by the site's distance from the UAA termination codon (in base pairs). Heavy lines are used to indicate the regions which have been sequenced. The exact locations of those restriction sites which have not been sequenced were estimated by extrapolating from those in regions where the nucleotide sequence is known and fitting with the amino acid sequence. The numbers indicate base pairs.

Fig. 3 Nucleotide sequence from the 5′ terminus of the 510-base pair *Alu*I pHb1003 insert fragment shown in Fig. 1. The corresponding polypeptide sequence is shown juxtaposed to the αA and αB globin primary sequences reported by Matsuda and Takei[3,5]. Sequence homology is indicated by the cross-hatched bars. The amino acids listed as evolutionarily conserved by Dayhoff[4] are enclosed in rectangles. The possible codons for amino acids 60–83 of the αA and αD are shown below the amino acid comparisons.

adult globin chain or one not previously recognised in 2–3-week-old chicks. Alternatively, it is possible that the stress of phenylhydrazine treatment causes these young chickens to synthesise other globin chains, as is known to be the case in sheep or goats. If so, this stress globin might represent activation of a globin gene not previously identified, or it might represent renewed synthesis of embryonic π or π' α-globin subunits or of haemoglobin H (the α subunit of which is uncharacterised).

The observed variations cannot easily be explained as the result of rearrangements in the cloned DNA; it is unlikely that such rearrangements could cause the observed variations while preserving the correct reading frame, the conserved residues at positions 69, 74, 80 and 83, and the proper spacing between these conserved residues. Nor is it likely that these variations are due to polypeptide sequencing errors: the amino acid sequence in question is bracketed by a tryptic fragment from Lys 61 to Lys 81 and a chymotryptic fragment from Leu 65 to Leu 80. Both these fragments are small and easily sequenced by the Edman (phenylisothiocyanate) and Sanger (dinitrofluorobenzene) methods used by Matsuda *et al.*

To test the hypothesis that pHb1003 might represent only a minor globin sequence, we have carried out a preliminary characterisation of other chicken globin cDNA clones. Twelve globin-insert-carrying plasmids identified from colony hybridisation studies were grown and analysed by cleavage with the restriction enzyme *Hae*III. Of the restriction patterns obtained, one showed a 248-base pair fragment characteristic of pHb1003. All but one of the remaining plasmids contained β-globin inserts as shown by the presence of a 66-base pair *Hae*III fragment. The remaining plasmid, pHb1008, showed a unique pattern and may represent an entirely different α- or β-globin gene sequence (A.Y.L. and Lee, unpublished results). The discovery of a second plasmid, pHb1010, with a restriction pattern similar to that of pHb1003 indicated that this is not a minor sequence in this mRNA preparation. It also made it possible to test directly the possibility of rearrangements in the cloned DNA. The ladder sequencing technique was used to compare the nucleotide sequences of plasmids pHb1003 and pHb1010 in the same region shown in Fig. 3. The sequence of pHb1010 was found to be identical to that found for pHb1003 in this region, but different from the sequence expected for the αA or αD mRNAs, as discussed earlier.

The fact that nine clones out of 12 showed the β-globin restriction pattern suggests two possibilities. The first is that the α-globin sequences were cloned at low frequencies, in which case we might have lost a specific class of α-globin mRNA. The alternative possibility is that α and β sequences were cloned with similar efficiencies but that the α clones give slightly lower signals in the colony hybridisation test so that they are somewhat under-represented among the 13 clones chosen for the most intense signals. Our experimental results show that this latter possibility is correct. When the colony hybridisation test was repeated with probes specific for the α- and β-globin genes (restriction fragments from pHb1001 and pHb1003 were used as probes), approximately equal numbers of α- and β-globin clones were observed (I.W.C., unpublished results).

On the basis of these results, we favour the hypothesis that the stress of phenylhydrazine treatment in these young chickens may cause the turn-on of synthesis of a stress globin. The complete sequence determination of the pHb1003 clone, which is now underway, will be helpful in establishing whether it codes for the embryonic π or π' α-globin subunits, or the α subunit of haemoglobin H, or for a novel stress globin such as occurs in sheep or goats. Interestingly, the amino acid variations observed between positions 60 and 83 generally retain the polarity and charge observed in the corresponding region of the αA polypeptide sequenced by Matsuda *et al.* With the exception of a Thr-to-Ile shift at amino acid residue 67, all the replacements combine to prevent an overall change in polarity or charge. The Asn-to-Glu change at residue 68 is opposed by a Glu-to-Asn change at position 71. The Ser-to-Ala shift at amino acid 77 is compensated by an Ala-to-Thr change at position 79. The remaining changes at residues 63 64, 70 and 73 all involve uncharged nonpolar amino acids.

Amino acids 60–83 occur in the EF 'corner' region of the α-globin polypeptide between the E and F helices (residues 52–71 and 80–88, respectively, by Kendrew's nomenclature[9,10]). The EF region bends around the haem and forms a part of the hydrophobic centre of the intact haemoglobin molecule. This suggests that for the chicken α-globin polypeptide the maintenance of correct charge and polarity in such bend regions may be more important than other features of protein stereochemistry.

This work was supported by USPHS grants GM 18586 and HL 21831. A.L. was supported by NCI predoctoral training grant 4–783825–32923–7.

Note added in proof: One of us (A.Y.L.) has completed the DNA sequence of pHb1003 (manuscript in preparation). The polypeptide sequence encoded by this plasmid insert differs from the adult αA globin at 23 positions and from the αD at 63 positions. At the same time the predicted tryptic cleavage products of this sequence would differ from those reported for the π and π' embryonic α-type globins. We are therefore led to conclude that pHb1003 encodes a previously uncharacterised αA-like globin.

Seismic evidence for Mesozoic sedimentary troughs on the Hebridean continental margin

JONES'S interpretation of seismic refraction lines on the NW British continental shelf[1] provides welcome corroboration of the Mesozoic sedimentary basin between the Flannan Isles and Lewis first postulated by Bullerwell (see refs 2–4). As we have already suggested that the Rockall Trough developed by seafloor spreading in the early Permian[5–7], we wish we could also welcome Jones' interpretation of the structure of the NW British margin, which suggests that the development of the Trough, at least in part, goes back to Permo-Triassic times. However, we interpret the high velocity refractor ($V_P = 4.4 \pm 0.3$ km s^{-1}) as corresponding merely to the top of a layer of Palaeocene–Eocene basalts, because (1) regional mapping and study of interval velocities using commercial 24-fold reflection lines and aeromagnetic coverage shows that basalts extend southwards from the Faeroes over almost the whole of the Rockall Trough north of Anton Dohrn seamount (as was suggested by Roberts[8]) and also over the outer NW Scottish shelf from the Wyville–Thomson Ridge to about 58° N; (2) the high-frequency negative magnetic anomaly field characteristic of these basalts at shallow depth is clearly seen both on Jones' magnetic profile[1] and on the IGS aeromagnetic map[2]; and (3) the refractor velocity is similar to that for basalts elsewhere on the NW European margin[9–11], but probably too high for Permo-Triassic sediments; although the interval velocity for pure Permo-Triassic sandstones at ~4 km depth in wells in the Viking Graben[12] and West Shetland Basin[13] can exceptionally attain values as high as 4.5 km s^{-1}, the usual range of velocity is 3.6 – 4.1 km s^{-1} for Permo-Triassic sandstones in these areas. The Permo-Triassic beneath the Little Minch has a $V_P \sim 3.9$ km s^{-1}, obtained by refraction shooting[14]. Above the basalts, the refractors with apparent $V_P \sim 2.8$–3.1 km s^{-1} could be due to Quaternary glacial till; measurements on data from the West Shetland area show that glacial till up to 100 m thick can have interval velocities $V_{\text{int}} \sim 2.6$–2.9 km s^{-1}. However, the Tertiary sediments between the Quaternary and the basalts have a lower V_{int}, so the top of the basalts is somewhat shallower than that given by Jones' profiles.

The gravity suggests that there may be sediments beneath the basalts, but we have no way of estimating their age. Thus we conclude that Jones' results have no relevance to the early evolution of the Rockall Trough, and, furthermore, his attempt to estimate the hydrocarbon prospects of this part of the margin is misleading; prospects here are poorer than elsewhere, because of the basalt cover. However, our reconstruction[7] suggests that in mid-Jurassic times Orphan Knoll was situated at the south-east margin of the Rockall Trough. The neritic Bajocian sands found beneath the Knoll[15] may therefore occur elsewhere along the margins of the Trough, and may also overlie downfaulted basins of Carboniferous age on the outer continental margin, developed during an intracontinental rifting phase[6] before early Permian spreading. Therefore along the margins clear of Tertiary basalt cover, for example, the south-east Faeroe–Shetland Trough margin between 60 and 62° N, and both margins of the Rockall Trough south of about 58° N, the hydrocarbon prospects may be very good.

JONES REPLIES—The uncertainties involved in estimating stratigraphical ages from seismic velocities in the Hebridean region were emphasised in my paper[1] and I am therefore grateful to Smythe *et al.* for their early comments. Although these are primarily based on their unpublished reflection profiles, velocity data and regional maps, some further pertinent remarks can be made.

Smythe *et al.* accept my conclusion that Mesozoic sediments occur immediately west of Lewis, an area in which the age of the sediment cover was previously undefined[2]. My inference that Mesozoic sediments also lie close to the sea floor north-west of the Flannan Ridge is based on the observation that the 2.8–3.1 km s^{-1} values on lines JM-9 and JM-10B are significantly higher than published velocities in Tertiary–Quaternary sequences[1]. Thus constrained, I was unable to interpret the deeper 4.0–4.4 km s^{-1} refractor as the top of a pile of Tertiary basaltic lavas. Using 'measurements on data' from an unspecified location near the Shetlands, Smythe *et al.* attribute the 2.8–3.1 km s^{-1} values to glacial till, which then allows them to suggest that the 4.0–4.4 km s^{-1} layer is much younger than I proposed. As they do not indicate the water depths in which the high Pleistocene velocities were determined, the method of measurement and also local velocity changes, it is not clear whether a direct comparison with shallow refractor velocities near the Flannan Isles is justified. Are their 2.6–2.9 km s^{-1} values sufficiently typical of the Pleistocene to permit an extrapolation over a large area? Their results may be of regional importance but as careful mapping by Eden[3] and others has revealed marked and often rapid lateral variations in Pleistocene deposits off northern Britain, Smythe *et al.* need to provide additional evidence to show that thick, high velocity boulder clay is likely to lie near the shelf break, some 300 km south-west of the Shetlands. They must also account in their interpretation for the presence of pre-Quaternary reflectors[4,5] within the westwards continuation of their proposed Quaternary sequence.

In their discussion of the 4.0–4.4 km s^{-1} refractor, four references are misleadingly quoted (their refs 10–13) to add weight to their contention that it represents Tertiary basaltic lavas and not pre-Jurassic sediments. Seismic velocities for basalts are omitted in ref. 10. Talwani and Eldholm[11] ascribe velocities near 4.4 km s^{-1} on the Norwegian margin, not to basalts, but to pre-Cretaceous sediments. A limiting 4.5 km s^{-1} for Permo-Triassic sediments is not included in their refs 12, 13. My values of 4.0–4.4 km s^{-1} seem to be well

0028–0836/78/0276—0420$01.00

within the permissible range for Permo-Trias as the refraction profiles of Browitt[6] show velocities of 4.6–4.8 km s^{-1} at a level in the West Shetland Basin where Cashion's sections[7] reveal thick sediments of this age. Thus, pre-Jurassic deposits cannot be dismissed at the depths I have indicated. They correctly note that magnetic anomalies occur over the 4.0–4.4 km s^{-1} layer but, rather than arising from Tertiary lavas, these can be interpreted as reflecting small basic intrusions within a thick Mesozoic section and magnetisation contrasts in the Precambrian basement.

In denying that my results are relevant to the early evolution of the Rockall Trough, Smythe *et al.* have ignored my demonstration of major faulting and crustal subsidence. As they accept a Mesozoic age for the Flannan Trough they must also accept the existence on the continental margin of NNE-trending faults which were active during Mesozoic time. As these run approximately parallel to the continental slope north of St Kilda and have increasingly larger displacements northwestwards[1], it is difficult to resist the conclusion that the faulting is directly associated with the major phase of downwarping in the Rockall Trough. My section showing thick pre-Jurassic sediments north-west of the fault-bounded Flannan Ridge is compatible with the Permian opening first suggested by Heirtzler and Hayes[8] but it does not establish that seafloor spreading took place at this time.

Commenting on petroleum prospects off northern Britain, Smythe *et al.* offer a comparison with other parts of the Rockall Trough that hinges on unpublished data and a geometrical argument which is questionable because the extent of oceanic crust in the region is unknown. Several parts of the Rockall Trough clearly deserve detailed commercial exploration, although my appraisal of prospects would be less sweeping than that given by Smythe *et al.* Moreover, in view of the geophysical indications of thick sediments and major Mesozoic faulting west of Hebrides, it seems premature for them to take a firm, pessimistic stand on a large section of the Scottish margin, especially since drilling investigations are at such an early stage.

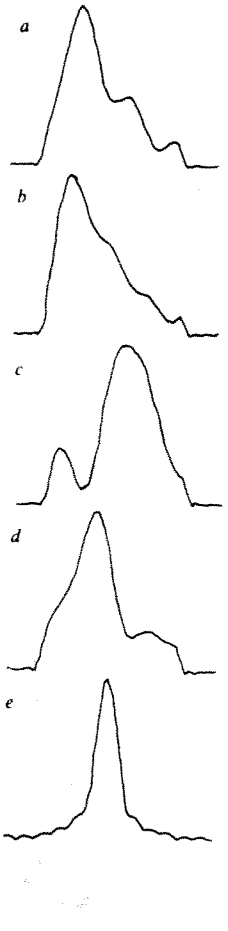
Object reconstruction from intensity data

GULL AND DANIELL[1] have recently proposed a new maximum entropy algorithm for the reconstruction of an object field from incomplete and noisy measurements of its Fourier transform. This new algorithm may encourage other workers to apply maximum entropy techniques to their own problems. For this reason we point out here that the application of maximum entropy techniques for object reconstruction in the absence of phase information could lead to wholly false conclusions due to ambiguities. We shall illustrate some of the problems using a specific example. Many such examples may easily be generated and the one chosen here is not unusual.

Figure 1 shows four different, real and positive objects which all give rise to the scattered intensity shown in Fig. 1*e*. Families of dissimilar objects whose Fourier transforms have the same modulus occur whenever the scattered intensity has non-zero minima[2]. Such minima indicate the presence of complex zeros in the scattered field. For each such zero there are two possible positions, which correspond to different objects whose Fourier transforms have identical moduli. The possible positions for these zeros are symmetrical with respect to the real axis and thus one speaks of 'flipping' zeros about this axis in order to generate different objects. The example in Fig. 1 was produced by 'flipping' such zeros. Clearly the four objects thus created are very different, for example, in the number and position of their peaks.

Fig. 1 All four different real positive objects shown in *a*, *b*, *c* and *d* produce the same far field intensity, shown in *e*. The four different objects have been generated by reflecting or 'flipping' the zeros of $F(z)$ about the x-axis, as described in the text.



The maximum entropy algorithm should converge to one of these possible solutions but the only criterion it has as a basis for the selection of that solution is that of smoothness, as all the possibilities are real and positive. However, inspection of the four possible solutions shows that none may be disregarded as unphysical—they are all 'smooth'. It would only be possible to identify one of these possibilities as the solution if one has some extra information, such as approximate phase values which may provide a basis for such discrimination. On the basis of the intensity alone there can be no unique solution, unless all minima are zero. The selection of one solution using an entropy criterion is dangerous. For example, if the algorithm chose the third solution one might conclude that the object consisted of two distinct peaks, whereas the other possible solutions show that such a conclusion is unfounded.

The example given here is simpler than may be expected in general—there are few complex zeros—and thus 'real' data may be expected to result in even greater ambiguity. In these conditions it is vital that some measure of the ambiguity is established. The maximum entropy algorithm does not give such a measure[3].

For convenience the analysis used to produce the example in Fig. 1 is one-dimensional but similar ambiguities will exist in two-dimensional systems.

Human reproduction reconsidered

MAY'S article in News and Views, '*Human Reproduction Reconsidered*'[1], fails to mention that the research on the demography of the !Kung hunter-gatherers, reviewed by Short and by

Kolata, is from my work. A brief report can be found in *Kalahari Hunter-gatherers*[2]. A full account, including data, methods and analyses (including a comparison with the Hutterites and a consideration of the implications of the Frisch hypothesis) will be found in my forthcoming book[3].

The figure of 15.5 yr for the mean age at menarche for !Kung girls (quoted by Kolata from a telephone interview) has been superceded by a mean of 16.5 yr, calculated from a larger group of observations. !Kung women may be anovulatory during some substantial portion of their birth intervals (mean length 35.4 months for all intervals observed during an eleven year period, $n = 102$) but they are not amenorrheic for this whole period.

It is tempting but premature to generalise from the !Kung to hunter-gatherers in general and hence to prehistoric populations. The low fertility of the !Kung suggests a stimulating hypothesis on the nature of population dynamics in such groups, as discussed by May, but exploring that hypothesis will require considerable additional research on other groups.

The neural representation of visual space

DRASDO[1], and Lennie[2], attribute Rolls and Cowey[3] with the demonstration that monkey cortical magnification factor, M, varies as the square root of the ganglion cell density which deals with the corresponding region of visual field. Lennie's discussion is based on the development of this relationship for monkey and man. In fact, Rolls and Cowey report M to be proportional to ganglion cell density deg^2, not to its square root, both within and outside the foveal area.

Such proportionality between retinal ganglion cell density deg^2 and M has also been described at several stations of the visual pathways in a variety of species[4–7]. It has been a long-standing puzzle as to why a linear measurement, M, should be proportional to a retinal cell density.

The outcome of Drasdo's data manipulations, that human cortical magnification factor is proportional to the square root of the ganglion cells serving the corresponding region of visual field (that is, of his receptive field density, D_r), is thus not at all in agreement with the findings of Rolls and Cowey. If valid, it is the first instance of such a relationship and implies that the human visual cortex is organised in a quite different fashion from that of saimiri or macaque, or indeed from that of cat and rabbit.

However, the data on which Drasdo's conclusions are based are not sound enough to warrant a belief that the human cortex deviates so markedly from the organisation apparently common to a variety of species. The ganglion cell distributions which he pooled[8–10] were all obtained by the unreliable technique of counting on radial sections not subject to an Abercrombie correction[11]. Also, there is no evidence of common criteria for ganglion cells, shrinkages were not measured and the distributions plotted separately can support quite different interpretations from those of Drasdo. It perhaps suffices to point out that the results of Van Buren indicate densities of from one to more than two orders of magnitude greater than those of Oppel at the equivalent eccentricity. Correction for optical magnification is a nicety in such circumstances.

Of course, it would be pleasing if Drasdo's conclusions were valid, because the recent demonstration[12] of proportionality between human acuity and cortical magnification factor could then relate acuity directly to ganglion cell angular separation. In my opinion the evidence is against such a relationship in man[13] or cat[14] but, as Lennie points out, knowledge of the distribution of the specific ganglion cell class involved in resolution tasks may elucidate the matter. *Note added in proof:* Lennie's editorial remains explicitly misleading. This might have been avoided had Drasdo emphasised that he claimed differences between man and monkey which necessitated analysis in terms of $\sqrt{D_r}$, rather than D_r, and M. However, I remain unconvinced; the densities of Van Buren and Oppel differ more than 100-fold at the same eccentricity in the original data quite independent of errors introduced by replotting; similar large discrepancies occur throughout their data and preclude pooling.

DRASDO REPLIES—Some responsibility is accepted for the scepticism evinced by Hughes, whose comments on my letter[1] can be traced to two irregularities on points of detail[2]. However, this scepticism should not extend to the material contents of the letter which can be shown to be unaffected. As Hughes indicates, the root sign in the first paragraph is regrettably misplaced. This relationship observed in animals was stated correctly in the following paragraph.

Apparent differences between the vision of man and other animals should not cause surprise. Even in other primates, predation, falls and fighting contribute largely to mortality[3]; survival may be related to peripheral and tectal vision, and correspondingly the human extra foveal retina has fewer presumed transient and feature-detecting ganglion cells[4].

The ganglion cell density distributions differed systematically; literally, to pool them would have been reprehensible. Instead, a mean line was taken between the two sets for each meridian (see Fig. 1, ref. 1). Shrinkage corrections for data of Oppel and Van Buren were based on fovea–papilla distance, which further reduces disparities by correcting for eye size. Paradoxically, Oppel's[5] original estimated total count fell short of Van Buren's[6] by only 40%, despite the extreme discrepancies referred to by Hughes.

I am indebted to Hughes, who inadvertently brought to my attention an incorrectly plotted point which, when corrected[2], reduced the discrepancy between cells and receptive fields in the area affected by excavation to 3%, giving further support to the calculation (see legend to Fig. 1, ref. 1).

The possibility of an overcount of ganglion cells is well known[6,7], but as with the other data used these were the best estimates available and all show an impressive alignment with the empirical equation which remains attractive for its simplicity and usefulness in the present state of knowledge.

Topics in Enzyme and Fermentation Biotechnology Vol. 2

edited by **A. Wiseman**, *Department of Biochemistry, University of Surrey.*

In the second volume of this series attention has been given to the balance of presentation between aspects of enzyme biotechnology. An interdisciplinary approach is favoured and subjects covered include the use of immobilised enzymes, the stability problems of enzymes in use and in storage, and the biological treatment of industrial waste water viewed as a fermentation process. It relates also to the utilisation of enzymes in many industries, including pharmaceutics, food, textiles and paper.

Further volumes in this continuing series are in preparation.

Analysis with Ion-Selective Electrodes

by **J. Vesely** and **D. Weiss**, *Geological Survey, Prague,* and **K. Stulik**, *Charles University, Prague.*
Translation Editor: R.A. Chalmers.

The simplicity of the apparatus and measuring techniques of ion-selective electrodes has made their application a growth field. This practical and up-to-date survey covers all aspects of the method, with emphasis on analytical uses. It gives detailed descriptions of experimental techniques, and discusses entire procedures from sample preparation and measurement, to result handling. The exhaustive listing of practical applications, ordered according to the ions or other species to be determined, is noteworthy. Appendixes containing many useful constants and conversion factors supplement and complement the text. The theoretical sections of the text are concise but thorough, and are documented with diagrams, tables and numerical values, and extensive references to the literature. *(Ellis Horwood Series in Analytical Chemistry;* Editors: R.A. Cognitive Processes in Animal Behaviour

by **S.H. Hulse**, *Johns Hopkins University,* **H. Fowler**, *University of Pittsburgh,* and **W.K. Honig**, *Dalhousie University, Halifax, Nova Scotia.*

This volume highlights cognitive functioning in animals providing a link between research and theory on animal learning and behaviour and human learning and cognition. Although the contributors represent different fields of learning and behaviour, from ethological and experimental approaches, the book gives a cohesive and well-knit set of arguments that can provide a cross-fertilization of the techniques, strategies and conceptualizations used by both those doing research with humans and those using animals.

reviews

Chinese technical endeavour

N. Sivin

The Shorter Science and Civilisation in China. Vol. 1. An abridgement by C. A. Ronan of J. Needham's original text. Pp.326. (Cambridge University Press: London, New York and Melbourne, 1978.) £7.95.

For twenty-four years, in eight volumes of *Science and Civilisation in China* (still unfinished), several associated books, and a multitude of essays, Joseph Needham and his collaborators have been demonstrating the richness and importance of China's scientific and technical traditions before modern times. They have surveyed historical studies by hundreds of scholars in China, Japan and the West, supplemented them with explorations of their own, and woven them into a coherent whole for the first time. The assumption that Europe produced the only civilisation ever capable of systematically understanding and manipulating nature has been current too long to disappear merely because it has been massively disproven. But now that notion is a badge of wilful ignorance. To replace it Needham has offered his ecumenical vision of man's relationship to nature as the one area of experience in which the global effort has been common and convergent over the past several thousand years.

Because the intent of his work is "extensive and pioneering", Needham's books—even collections of essays and lectures such as *The Grand Titration* and *Clerks and Craftsmen in China and the West*—have been speculative in the best sense, closely argued, and massively documented. The latest volume of *Science and Civilisation in China*, a historical survey of alchemy, for instance, contains, alongside 262 pages of text, 169 pages of closely spaced bibliography. It brings the number of illustrations in the series so far to 1373.

After using Needham's publications in courses on Chinese science and medicine at MIT and the University of Pennsylvania for a dozen years, I can report that bright undergraduates with some experience in and taste for historical studies usually find these books readable and stimulating; that other students (especially science and engineering students, whose ability to learn outside their technical fields tends to atrophy in American universities) find them too dense; and that they are too expensive for students to own. The demand for a cheap, simplified version of Needham's survey, for students and others who want to live with the issues he raises, is therefore obvious. This book will satisfy it admirably.

The volume in hand covers Volumes I and II, on history, geography, the travel of scientific knowledge, and the history of philosophy, all seen from the special vantage point of science. Practically every aspect of Chinese technical endeavour since the New Stone Age is touched upon, with constant attention to corresponding aspects of other civilisations. This condensed version begins a new series of unspecified length.

Colin Ronan (who refers to Needham in the third person throughout) is an experienced author of books on science and its history for a general readership. He provides a straightforward condensation, with well-conceived minor rearrangements. He expresses himself clearly and simply, and preserves a good deal of Needham's nuance. The new version provides slightly over a third as much text, nearly as many tables, and more than half as many illustrations (some new), as the volumes abridged. The book is reasonably priced by current standards, and no doubt will become the first of Needham's books on China (in English, at least) to be published in paper covers.

The idea of a multi-volume abridgement is not intuitively obvious, but there is a great deal to be said for a level of detail that will put the gist of Needham on physics and physical technology, or on alchemy, protochemistry, and chemical technology, into one volume. Since the final fascicle of *Science and Civilisation in China* is nowhere in sight, the alternative to a serial abridgement would be an indefinite wait for a superficial single volume.

This book has several limitations of which its readers should be aware. Most important, it is based on writing roughly a quarter-century old. Needham's intellectual reach and the open-endedness of his arguments have made his writing less prone to obsolescence than most other Sinological surveys of the 1950s. His is still the only one that emphasises the scientific and technological components. Nevertheless, our understanding of many matters has been altered fundamentally by the burst of scholarship on China generally, and Chinese science particularly, in the past two decades.

Ronan has interpolated concise notes on important new discoveries and changes in chronology, and has corrected minor errors. But major re-writing, which would be the only way to incorporate important re-interpretations by Needham and many other scholars, is clearly not feasible. None of the investigators capable of fundamental re-writing — which would amount to a new synthesis of the field —is prepared to undertake it, and none known to me could produce a book as readable.

I find Ronan's condensation generally faithful. There are a few points where Needham's assertions are mashed beyond recognition—for example, to produce assertions that the Taoists favoured scientific logic (p83), that Shen Kua's late-eleventh-century account (publication misdated, p157) "is probably the first record in any language of the precipitation of metallic copper by iron", and that ancient Tantric Buddhists "adopted in their symbolism what we might call 'electrical energy' " (p271).

The bibliography is short, but not too short. It would have been more serviceable if the many mediocre and outmoded books had been omitted and more references to important introductory works and critical appraisals published in the past decade or two had been substituted for them.

Ronan's own view of the Chinese tradition, as set out in his brief introduction, puzzles me. To give only one example, the assertion that "before the Jesuit arrival Chinese science was quasi-empirical—based on observation and experience, with theory in a comparatively undeveloped state" ignores not only important parts of *Science and Civilisation in China* but many studies published by other historians in recent decades.

This and other puzzling notions in the introduction do not intrude upon the summary of Needham's arguments, but an introduction that explained the most important changes in our understanding in the past twenty years or so would have been a great help to readers.

All in all this first volume of *The Shorter Science and Civilisation in China* provides a splendid orientation to the cultural matrix of science and technology. It will motivate many readers to seek out more recent discoveries and interpretations. A large public will await Ronan's coming adaptations of Needham's histories of science, techniques and medicine. ☐

N. Sivin is Professor of Chinese Culture and of the History of Science at the University of Pennsylvania.

Electrical breakdown phenomena in gases

Electrical Breakdown of Gases. Edited by J. M. Meek and J. D. Craggs. Pp. 878. (Wiley: Chichester, UK, and New York, 1978.) £35; $75

THE book of the same title published in 1953 is well known as a standard reference book to engineers and physicists concerned with the many aspects of electrical breakdown phenomena in gases. This welcome new version, edited by the original authors, updates much of the material in the original volume and takes account of the many advances made over the past 25 years Inevitably the contents reflect changes of emphasis and new areas of current interest Discussion of lightning discharges and glow-to-arc transitions is now omitted but a chapter on laser induced breakdown has been included.

As in the original volume, chapter 1 is concerned with a discussion of the fundamental collision processes relevant to breakdown phenomena. This includes basic definitions and a description of electron scattering processes, negative ion formation, collisions involving molecular species, electron–ion and ion–ion recombination, and drift and diffusion of electrons and ions.

Chapter 2 is concerned with vacuum breakdown including a discussion of field emission, microdischarges and microparticle pre-breakdown phenomena. The discussion of spark breakdown in uniform fields in chapter 3 includes a full description of pre-breakdown ionisation in gases in steady-state conditions, electron avalanches, ionisation coefficients, and temporal growth of ionisation in impulse conditions.

A general treatment of corona discharges is given in chapter 4, and chapter 5 is concerned with spark breakdown in non-uniform fields. Breakdown voltage characteristics in both uniform and non-uniform fields are considered in chapter 6 for a wide range of gases and gas mixtures.

Chapter 7 deals with the time lag between the application of an impulse voltage and the consequent breakdown of a gas in terms of the so-called 'statistical time lag' and the formative time lags associated with the initiation and development of a discharge across a gap. In chapter 8, high frequency breakdown of gases is discussed in terms of radio and ultra high frequencies in air and sulphur hexafluoride

Laser induced electrical breakdown of gases is discussed in chapter 9. The intensity of a focused monochromatic beam is considered, together with its application to multiphoton absorption, ionisation and breakdown. Spark channels, which in recent years have become important in the design of opto-electronic devices of high sensitivity are considered in chapter 10. A short description of electrode effects is given in chapter 11.

Nine different well established researchers have contributed to this volume and they and the editors should be congratulated in achieving an unusual uniformity of style for a book of this type. Unnecessary overlap of material between chapters is minimal and the many excellent diagrams and illustrations throughout the book add to its attractiveness. It is a very readable book and should appeal to specialist researchers, postgraduate students, and readers whose interests lie only on the periphery of the general field of breakdown phenomena

H. B. Gilbody is Professor and Head of the Department of Pure and Applied Physics at The Queen's University of Belfast, Northern Ireland.

Liquid properties

Liquids and Their Properties: A Molecular and Macroscopic Treatise with Applications. By H. N. V. Temperley and D. H. Trevena. Pp.274. (Wiley: Chichester, UK and New York, 1978.) £15.

THE research work of the two authors of this book, Professor Temperley and Dr Trevena, lies, respectively, in the statistical mechanics of phase transitions and in the experimental study of the physical properties of liquids These fields exemplify the 'molecular' and the 'macroscopic' of the book's subtitle.

In the first field we have chapters 1–4 on intermolecular forces and statistical mechanics, chapter 10 on liquid structure and chapter 12 on transport properties. The rest of the book is mainly macroscopic: changes of phase, hydrodynamics and acoustics, liquids under pressure and tension (an interest shared by the authors), the gas-liquid surface, mixtures and solutions, and non-newtonian liquids. There is a final chapter on the unusual properties of liquid helium.

To cover this range of material in 270 pages allows only an elementary treatment The book aims to provide "what every good scientist, whether in research, teaching, industry or medicine should know about liquids." It is, perhaps, most successful in doing this on the macroscopic side, where the more descriptive narrative places less demands on the reader. The classical equations of hydrodynamics are derived painlessly with scarcely a result in vector notation that is not followed by its cartesian equivalent. Statistical mechanics is less easily handled this way and its equations have to be stated rather than derived if the book is to cover the wide range of subjects promised by the chapter titles.

Within these limitations the authors succeed in giving convincing and easily read accounts of their chosen topics. They are not entirely successful in the admittedly difficult job of relating the molecular side to the macroscopic. Moreover, some of the molecular theories discussed are now quite obsolete, such as the 'hole' and 'tunnel' theories of liquids and the lattice theories of liquid mixtures. There is a place in books of this kind for theories that are technically obsolete if they are physically informative (the authors rightly describe the theories of van der Waals), but not for theories which are now obsolete and which never did do justice to the basic physics. More recent and useful theories are, however, also described clearly, with particular emphasis on those put forward by the late Professor J. G. Kirkwood, to whom the authors rightly pay tribute.

The book is well produced and unusually free from misprints.

J. S. Rowlinson is Professor of Physical Chemistry in the University of Oxford, UK.

Climate and Evolution

Ronald Pearson

November/December 1978, xii + 274pp., £14.00/$29.00 0.12.548250.7

One of the first synoptic treatments of two separate issues — the understanding of evolution and the problem of climate. It introduces the reader to information from a wide variety of relevant fields, and focuses attention upon the apparent synchroneity of past geophysical events, changes in the world's flora and fauna, and periods of historical importance. It will be of immediate interest to undergraduates and research workers in biology, climatology, geology and geography, and should encourage readers to appreciate the relevance of their data to an overall panoramic view of climate and evolution.

The Genetics and Biology of Drosophila

Volume 2b

edited by M. Ashburner and T. Wright

November 1978, xvi + 602pp., £29.60/$61.25 0.12.064941.1

Contents

J. Grossfield. Non-sexual behaviour of *Drosophila. L. Ehrman:* Sexual behaviour. *E. Gateff:* Malignant and benign neoplasms of *D. melanogaster. J. C. Sparrow:* Melanotic "tumours". *M. Ashburner and H. D. Berendes:* Puffing of polytene chromosomes. *T. M. Rizki:* The circulatory system and associated cells and tissues. *H. D. Berendes and M. Ashburner:* The salivary gland. *A. C. Crossley:* The morphology and development of the *Drosophila* muscular system. *T. M. Rizki:* Fat body. Author index. Subject index. Species index. Index of genetic variations.

The Genetics and Biology of Drosophila

Volume 2c

edited by M. Ashburner and T. Wright

December 1978/January 1979, xiv + 610pp., £32.00/$66.25 0.12.064942.X

Contents

A. Wessing and D. Eichelberg: Malpighian tubules, rectal papillae and excretion. *M. J. Lamb:* Ageing. *S. L. Fullilove and A. G. Jacobson:* Embryonic development — descriptive. *P. J. Bryant:* Pattern formation in imaginal discs. *N. M. Hodgkin and P. J. Bryant:* Scanning electron microscopy of the adult of *D. melanogaster. J. H. Postlethwait:* Clonal analysis of *Drosophila* cuticular patterns. *A. Shearn:* Mutational dissection of imaginal disc development. *W. J. Gehring:* Imaginal discs determination. *E. Hadorn:* Transdetermination. Author index. Subject index. Species index. Index of genetic variations.

Pesticide Microbiology

Microbiological Aspects of Pesticide Behaviour in the environment

edited by I. R. Hill and S. J. L. Wright

December 1978/January 1979, xx + 844pp., £38.00/$78.65 0.12.348650.5

This book presents the subject of pesticide microbiology in a balanced and authoritative way, neither minimizing nor over-emphasising the risks involved in our chemical interventions in the environment, and focusing attention on the diverse microbiological aspects of the fate and behaviour of pesticides. It describes how microbes can affect the activity and persistence of pesticides and how, in turn, pesticides can influence the activities of these members of the non-target biota. It recognises, too, that interactions with microbes cannot be considered in isolation from other (physical, chemical and biological) factors concerned with pesticide behaviour in the environment.

Biochemical Mechanisms of Liver Injury

edited by T. F. Slater

November/December 1978, approx. 850pp., £40.00/$82.75 0.12.649150.X

The book is primarily concerned with describing the variety of biochemical disturbances underlying a number of important liver injuries and diseases. Certain aspects in particular are emphasised, such as the role of metabolic activation of many hepatotoxins and hepatocarcinogens in the development of liver injury; the transient nature of such activated intermediates which makes rapid reaction studies necessary for their investigation; the importance of free radical reactions in the biochemical disturbances produced by these transient intermediates; and the multiplicity of protective mechanisms that may be applied. The book also includes some chapters dealing with the applications of relatively new techniques such as electron spin resonance, and nuclear magnetic resonance.

Trends in Pharmacological Sciences

'TIPS' for 1979!

With the first issue scheduled for publication in the third quarter of 1979, 'TIPS' will aim to provide a focal point for major issues and developments in all aspects of pharmacology. Reviews, news articles, features and book reviews will provide the pharmacologist with a vital source of information, eliminating time-consuming searches for knowledge of events in his own or related areas. Combining the topicality of a newspaper with high academic standards, 'TIPS' will act as a pivot in the pharmacology world, providing a forum for the fruitful exchange of ideas, views and news.

Under the guidance of a distinguished international editorial board, 'TIPS' will embrace every major aspect of the field - from basic pharmacology, clinical pharmacology, molecular pharmacology, drug monitoring and therapeutics, to toxicology and food additives. Remove futile searches for information from your daily routine and keep in touch through 'TIPS'.

First issue scheduled for the third quarter of 1979

Cosmic travelogue

Beyond the Moon. By P. Maffei. Pp. 376. (MIT Press: Cambridge, Massachusetts, and London, 1978.) $12.50; £8.75.

Beyond the Moon is a cosmic travelogue that takes us at ever-increasing velocities from the inner Solar System to the depths of the Universe. The purpose of adopting this unusual approach is to heighten the reader's awareness of the vastness of space. Some feel for the immensity of the heavens is conveyed by occasionally looking back at the Solar System until the Earth and Sun disappear from view. To adopt such a style of writing is a bold stroke: on the one hand it may captivate the curious reader, but there are points at which the description of the journey becomes altogether too precious and perhaps out of place in a scientific book.

Thus, on p167 we plunge into the cliché of holiday guide "Having witnessed the phastasmagorical spectacles of double stars and the cataclysms of novae and supernovae, we now set our sights on other goals . . .". Just round the corner to the Orion nebula: ". . . we tend at first to hold our breath, as if for fear that these tenuous veils will come undone . . . but the nebula remains . . . changeless in its very evanescence". The metaphor looks overworked even in the local stellar neighbourhood, where super-drive would be needed to dive through worm-holes of space in order to complete the itinerary.

For those willing to admit that suspension of disbelief necessary for enjoying science fiction, *Beyond the Moon* is a good read. It describes the Solar System, the nearest stars, and our Galaxy. Among the many commendable features is a surprisingly thorough survey of variable stars, a topic often skimped in popular writing. About one-third of the descriptive prose is a ramble through the extragalactic universe. Five appendices round off the journey, and there is also an outstanding index for those wishing to retrace their steps.

In no sense is *Beyond the Moon* a complete course in astronomy (neither author nor publisher claim that it is); rather it is like a series of extended essays in which the author is at his best when drawing out the themes that appeal to him particularly. His style and approach compares favourably with Asimov but lacks the incisiveness of Hoyle's writing at this same level.

Already *Beyond the Moon* has run through six editions in Italian, and it deserves to sell well in the English language. The translation and up-dating by D. J. K. O'Connell, S.J., of the Vatican, reads smoothly. Occasional lapses grate a little to anglophones (". . . the Protestant minister David Fabricius") and some analogy requires a good knowledge of Italian geography, such as knowing the distance by road from Rome to Genoa. This, however, is nit-picking, for O'Connell has done a fine job to this best-seller.

To whom is the book addressed? In the English language it must stand up to far more competitors than in its mother tongue. However, it seems admirably suited to that legendary and industrious hero of publishers' blurbs: the intelligent layman. It is a good account for the inquisitive but uninformed.

Simon Mitton

Simon Mitton is Secretary of the Institute of Astronomy, University of Cambridge, UK.

Structure of food webs

Food Webs and Niche Space. By J. E. Cohen. Pp. 189. (Princeton University Press: Princeton, New Jersey, 1978.) Hardback £9.40; paperback £4.65.

ECOLOGISTS have been surprisingly myopic about food webs. They have described them; complained about how complicated they are (the "tangled knitting hypothesis"); noticed that the number of trophic levels is never very many; perhaps commented on the fact that some seem to be compartmentalised; and then got on with the serious business of studying single-species populations, interspecific competition, species-frequency distributions and what have you. Questions about the shape of entire food webs within which the ecological play actually takes place, have hardly ever been asked.

In this book Cohen assembles data on thirty-one food webs, accumulated over four decades of field work by other biologists. He claims no first-hand knowledge of the natural history of the plants and beasts involved, but seems to have been meticulously careful in reading what others have written about them. He then analyses the structure of these food webs, focusing on patterns of food sharing. Specifically, he asks whether the overlap in food utilisation among various kinds of organisms can be represented in one dimension, or more formally as an interval graph. Cohen's central conclusion is that community food webs are interval far more often than chance alone would provide.

A great deal of the book is taken up with deciding what chance will provide if she is allowed to design random food webs—to generate the hypothetical tangled knitting as it were. Thus, after setting the scene and gently introducing his reader to the jargon of graph theory and combinatorics in chapters one and two (it sounds more difficult than it is) Cohen moves to a description of his real food-webs in chapter three.

Chapter four contains a major statistical analysis of the properties of these webs, and reveals a number of hitherto unexpected properties over and above the surprising fact that most, perhaps all real webs are interval. For example, the number of kinds of prey is roughly three-quarters the number of kinds of predators in all the community webs; the number of links between the bottom of a food chain and the top is highly constrained but has different distributions in different webs; and as a multiple of the number of predators in the food web, the distribution of dietary overlaps is roughly uniform. There is much food for thought in these, and the other empirical patterns revealed in this part of chapter four.

The remainder of chapter four and part of chapter five discuss a series of model worlds; seven random webs constructed under a variety of assumptions and constraints. (A large part of chapter five is also devoted to the clinical diagnosis of a sick, or at best perverse random number generator, and says much about Cohen's meticulous care in the analysis of both data and models.) The main conclusion from this, the core of the book, is very clear. The high frequency of interval webs in the real world is extremely unlikely to have arisen by chance.

The remainder of the book is devoted (in chapter six) to asking why food webs should be interval. Cohen runs through three minor, and three major possibilities. I must confess that of the three interesting hypotheses, I found one so vague, and one so esoteric mathematically that I did not understand them. The third, focusing on the notion that there are dynamic constraints on the design of food webs, is to my mind the most interesting. Cohen's use of qualitative stability analysis merely scratches the surface, and indeed may be misleading as a large number of webs that are qualitatively stable turn out not to be locally stable when parameters are assigned and the models analysed properly. There is much scope for further work here. Finally, chapter seven flies away into some fairly esoteric air—the higher corners of Euclidean space and intersection graph theory—which may keep the pure theorists happy but is unlikely to lead to many empirically testable hypotheses in the foreseeable future.

Obviously, the main empirical patterns which Cohen finds are only as good as the data on which they are based. Cohen himself is transparently honest about most of the weaknesses in his data, in the second part of chapter seven. There is no need to repeat them here. He also has some extremely perceptive remarks to make about data collection, and if the book does no more than encourage field biologists to collect new data on food webs that are specifically designed for and directed towards testing Cohen's hypotheses, it will have done a great service.

The main weakness in the data, however, is side-stepped by Cohen. In place of "species" he is often forced to use "kinds of organisms", and these may be very broad categories—for example, "spiders" feeding on "collembola" in Figure 1 Without wishing to nit-pick, there are actually rather a large number of species of collembola, and even more sorts of spiders even in the one Canadian willow forest to which this particular web refers, and they are not usually trivial components of terrestrial ecosystems. Thus, properly constructed, this and I would guess most of the other food webs might look totally different I do not know whether they would still be interval graphs, or how many of the other generalisations would still apply. This is decidedly not to say that Cohen should never have done the analysis in the first place. If ecologists always wait for perfect data nothing very interesting is going to get done Nor will people ever suspect that there are theoretical problems worth solving with better data But in this particular case we must definitely beware of the data, embrace the vision (Cohen claims that he got the idea in a dream), and take the book as a grand hypothesis More than anything else, I hope that Cohen's contribution will stimulate others to look more seriously at the design of foodwebs.

John H. Lawton

John Lawton is a Senior Lecturer in Ecology in the Department of Biology at the University of York, UK.

Utilising phosphate resources

Phosphorus in the Environment. Its Chemistry and Biochemistry. Ciba Foundation Symposium chaired by R. J. P. Williams Pp. 320. (Elsevier: Amsterdam, 1978.) $31 75; Dfl.72 60.

THIS symposium report contains 16 papers given by a diverse group of experts on the utilisation of the world's phosphate resources The coverage is very wide; and chemical, biological, technical, ecological and economic factors are all discussed. Almost everything gets a mention. methods of birth control, water closets, marsh gas, nerve gas, toothpaste, detergents and even such mundane items as the current price of phosphate rock

Although the pure chemistry content is somewhat limited, the book abounds with statistics, predictions and speculations about the future of mankind and how it will be linked to the availability of phosphorus. Reserves, consumption and the eventual fate of the element as utilised by man are critically discussed at some length

Not unnaturally, there are differences of viewpoint and some contradictions in the data supplied by different authors. The symposium, nevertheless, makes a serious, valuable and timely contribution to its subject. Individual papers are of a high standard and the discussions are particularly informative

An obvious message emerging from the symposium is that fertilisers will always constitute the most important use for the element, and if a rapidly expanding world population is to be fed, the conservation of phosphate supplies is already a matter requiring serious attention

Phosphates are not in themselves harmful to life, and pollution problems arising from their use are local, often controllable, and are probably somewhat overrated.

With perhaps as much as three-quarters of the world's phosphate reserves lying in Arab countries, these reserves will undoubtedly, in the long term, prove to be their most valuable asset. Unlike oil, which can be replaced by alternative energy sources, phosphorus is irreplaceable in life systems

It is pointed out that the complete natural cycle of phosphorus, unlike those of other major life elements, probably extends over many millions of years. This may be associated with a natural depletion of dry-land deposits and a temporary build-up of phosphate on the ocean floor. It is argued by some that the sudden and rapid exploitation of phosphorus compounds during the past 100 years, and the continued increase in their rate of consumption, will in a century or so lead to exhaustion of dry-land phosphate rock supplies

It would therefore seem prudent not to worry unduly about detergents, but rather to concentrate on improving the present low efficiency of uptake of phosphorus from soils This might be done, either by modification of existing fertilisers and soil systems, or by genetic engineering of suitable new plant species.

The eventual exhaustion of dry-land deposits, if this is to be believed, may one day necessitate direct sea-bed phosphate mining Alternatively it may be possible to obtain food from suitable sea plants which could utilise phosphate directly from the ocean.

This is not a book for a newcomer, but it should appeal to all those with some previous knowledge of the subject who have wide interests in phosphorus science

D. E. C. Corbridge

D. E. C. Corbridge is Lecturer in Chemistry in the University of Leeds, UK

Microbial growth in extreme conditions

Microbial Life in Extreme Environments Edited by D. J Kushner. Pp. 465. (Academic. London and New York, 1978) $40 50; £19.60.

THIS book needed to be written in view of the increasing significance of microbial growth in extreme conditions. The extreme environmental conditions chosen are principally physical ones: extremes of temperature, pressure, pH value, water and salt activities and radiation. Heavy metal toxicities are also included This selection may be considered rather arbitrary, as it excludes the class of extreme environments caused by deficiencies of nutrients—for example, the trace elements, although excess of these elements is dealt with under toxicities.

A great interest of extreme environments is that the description of their effects may throw light on the effects of the normal or non-extreme environmental conditions. The special adaptations revealed may suggest possible new technological applications of the microbes. However, the main motivation of these studies has been to explain microbial ecology

Many of the articles tend to be catalogues of facts which are useful for reference but not compelling reading. Also there is much turgid description of effects due partly to a lack of use of the quantitative parameters of growth such as specific growth rate and lag period.

The state of knowledge in the field seems to be in an early descriptive phase. The development of general explanatory principles will require much more study in depth of the problems from a whole organism viewpoint as well as molecular study. The reader will find in this work the growing points of the subject as well as a valuable reference source.

S. J. Pirt

S J. Pirt is Head of the Microbiology Department at Queen Elizabeth College, University of London, UK.

obituary

James Craigie

PROFESSOR JAMES CRAIGIE, O.B.E., F.R.S., distinguished for his wide research in bacteriology, died in Edinburgh on 26 August 1978, aged 79.

He was born in 1899 and educated in Perth and at the University of St. Andrew's, where he qualified M.B., Ch.B. in 1923, and later Ph.D. and D.P.H. He was appointed assistant in bacteriology at the University in 1927. In 1931 he moved to the Connaught laboratories, University of Toronto, first as research associate, later as lecturer in epidemiology and, in 1946, Professor of Virus Infections. He returned to Britain in 1947 to join the staff of the Imperial Cancer Research Fund.

Craigie's introduction to microbiology was in the laboratories of St. Andrew's University under Professor W. J. Tulloch. Here he carried out work on the serology of typhoid and, with Tulloch, worked and published on the 'flocculation' reaction which occurred when vaccine lymph was mixed with vaccinia-immune serum. He continued these studies when he moved to Canada.

He showed that the 'flocculation' was due to a combination of agglutination of virus particles and precipitation of a soluble substance. Further studies with F. O. Wishart revealed that the precipitable substance consisted of two elements, one heat-labile (L), the other heat-stable (S). By ingenious techniques, separate antibodies against the L and S fractions were obtained; it became clear that a complex antigen (LS) containing both substances was present on the surface of the virus particle.

Following work over several years on the antigenic properties of typhoid bacilli, his most important contribution to knowledge was his work on typhoid bacteriophages. With K. F. Brandon he described in 1936 a phage specific for strains of *B. typhosus* (now called *Salmonella typhi*) containing what he described as Vi-agglutinogen. With C. H. Chen in 1938 he found other typhoid phages divisible into four types according to a range of properties. One of these (Type 2) developed a high selective lytic activity for the strain of *B. typhosus* on which it was propagated. Its activity could be regularly modified by changing the strain on which it was grown. With this research tool they found that typhoid bacilli could be divided into a number of types (24 were known by 1947). Strains which could be related on epidemiological grounds all fell into a single type. Here, then, was a method of great value in epidemiology, whereby evidence could be obtained as to whether individual infections could or could not be traced to a common source. The finding has had wide repercussions, for similar methods have been applied to the differentiation of strains of various salmonellas and other organisms.

During the Second World War Craigie was one of a number of workers concerned in developing a vaccine against epidemic typhus, and he also studied the serological relations of epidemic and murine typhus. He was a member of a joint United States-Canadian Commission which organised work on protection against rinderpest; it was feared that the enemy might try to introduce the disease into North America.

In 1946, W. E. Gye, the Director of the Imperial Cancer Research Fund, was touring North America to learn of developments in the cancer field, and Craigie accompanied him. Gye then persuaded him to return to Britain to the Fund's laboratories at Mill Hill with a view to becoming Director; this he did, succeeding Gye in 1949.

Gye, always a passionate believer in the virus theory of cancer held that the survival of mammalian tumour cells after freezing or drying indicated that cellular survival could be ruled out, and that a virus must be concerned. Craigie, however, showed that in frozen tissues, some particularly resistant cells might survive in a modified, 'paramorphic' state. He designed a very effective tissue mincer, and, more important, a cabinet for preserving transmissible tumours at -70 °C. As a result, numerous propagable tumours, especially those of mice, could be preserved for years; no longer was it necessary to passage them *in vivo* at frequent intervals, and much time and money were saved. His last work was on Tyzzer's disease of mice, a very troublesome infection in mouse colonies; he was able to cultivate the causative organism (*B. piliformis*) in fertile eggs.

Craigie was not really happy as Director, preferring to concentrate on his own research and in 1957 he was allowed to do this, Dr R. J. C. Harris assuming overall responsibility for directing the Mill Hill laboratory.

In 1929 Craigie married Margaret Fotheringham, who predeceased him. He is survived by two daughters. He was elected F.R.S., Canada, in 1946 and F.R.S., London, in the following year.

He will be especially remembered for the leading role he played in Canadian microbiological research, especially in the years before and during the war, when work on viruses was developing so rapidly.

C. H. Andrewes

Harold Fletcher

DR HAROLD ROY FLETCHER, Queen's Botanist in Scotland, Regius Keeper of the Royal Botanic Garden, Edinburgh, from 1956 to 1970 died in Edinburgh on 27 August 1978. Born in Glossop, Derbyshire, he studied under Professors Weiss and Lang in Manchester and then moved to the Department of Botany of the University of Aberdeen as assistant to Professor Craib.

In Aberdeen his first responsibility—to his later amusement—was to teach plant physiology, but he soon turned to his main scientific interest, plant taxonomy and gained a PhD in 1933 for work on the Verbenaceae of Siam. At the same time he had a taste of plant collecting in the Faroes and Iceland and experience of the montane flora of Scotland for which he had an abiding affection.

In 1934 he moved to the Royal Botanic Garden, Edinburgh, then under the direction of Sir Willian Wright Smith and continued work on Asiatic floras gaining a DSc from Edinburgh University in 1939. Then followed a most rewarding period working on the rich collections of Chinese plants including a monograph of the genus *Primula* in collaboration with Sir William. At the same time he taught many university courses in botany, especially a course in taxonomy, which in its modern synthetic approach had no equal in Britain. Several strong modern currents in plant taxonomy in Britain flowered from these lectures.

During the years 1951–54 he turned his attention to horticulture—he had a rare eye for 'a good plant'—as Director the Royal Horticultural Society's Garden at Wisley in Surrey. And from this stemmed his activity in horticultural nomenclature as secretary for ten years of the International Commission for Horticultural Nomenclature and Registration and his detailed enumeration of Rhododendron cultivars —all recognised by his award of the Royal Horticultural Society's Victoria Medal of Honour in 1956.

A year after his return to the Edinburgh Garden in 1955 he succeeded Wright Smith as Regius Keeper. Immediately his energy and enthusiasm were thrown into rejuvenating botany and horticulture in the Garden, in Edinburgh, in Scotland and further afield. He relentlessly badgered authority to give him the necessary resources and so built a new herbarium and library in 1964 and new glasshouses in 1967. The staff was enlarged and better equipped, the outlook in taxonomy and horticulture remoulded and the training of horticulturists recast.

His continuing interest in botany in Scotland found an outlet in stimulating the post-war revival of the Botanical Society of Edinburgh but his much wider interest in world botany led to his advocacy of Edinburgh as the site of the Tenth International Botanical Congress. For this Congress in 1964 he shouldered much of the planning as general secretary. This Congress placed botany in Edinburgh before a wide audience, but in addition by travels and lectures, especially in North America, he formed strong personal links worldwide—especially as President of the International Association of Botanical Gardens 1964–69.

His outstanding devotion to Botany in Scotland was recognised by his much cherished appointment as Queen's Botanist in Scotland in 1967, as an Honorary Professor of Botany in the University of Edinburgh in 1968 and by the award of honorary DSc's by Edinburgh in 1971 and St Andrews in 1972 and the Patrick Neill Prize by the Royal Society of Edinburgh 1971–73.

His interest in writing and horticultural and botanical history found an outlet in his *Story of the Royal Horticultural Society 1804–1968* in 1969 and (with W. H. Brown) *History of the Royal Botanic Garden, Edinburgh 1670–1970* published in time for the garden's tercentenary celebrations. Following his retirement in 1970 he wrote a detailed account of the plant collecting travels of Ludlow and Sherriff—*A Quest of Flowers*.

Throughout his professional life he had a deep love of the arts especially literature, music and painting of which he had a discriminating collection. In his retirement he found more time for these pursuits and served as Chairman and then as a member of the Governors of the Edinburgh College of Art.

Harold Fletcher was possessed of a most remarkable blend of science and the arts intermingled with a strong human compassion. His taxonomy was science tinged with art, his administration science guided by humanity Throughout his life he drove himself hard and was loyally and very knowledgeably supported and encouraged by his wife Betty and by his son and daughter.

D. M. Henderson

John Marwick

DR JOHN MARWICK, the leading palaeontologist in New Zealand during the middle decades of the twentieth century, died in Hawkes Bay, New Zealand, on 16 August 1978, at the age of 87.

The son of an Orkney wheelwright who migrated to Otago in the eighteen-eighties, Marwick was educated at Oamaru, attending Waitaki Boys' High School, where the rector, Dr R. H. Don, was changing the bias of the curriculum from classical to scientific, stimulating an interest in geology by classes and excursions such as were seldom available to secondary school boys. Entering the teaching profession, Marwick attended Otago University, graduating M A. with first class honours in geology, and winning the Ulrich Memorial Medal in mineralogy and petrography, thereafter teaching in South Canterbury for two years before the outbreak of World War I. In the Middle East (1916–19) he served in the Camel Corps and N Z. Mounted Field Ambulance, was twice wounded and was awarded the Military Medal.

On his return from the war, Marwick was appointed to work in palaeontology at the New Zealand Geological Survey (then under the Mines Department, but later a division of the Department of Scientific and Industrial Research). His research on Tertiary molluscs led in 1924 to the award of D Sc. (University of New Zealand) for a revision of New Zealand Veneridae (Bivalvia).

Between 1921 and 1976 he published about 125 papers, reviews, and bulletins, his research continuing for 20 years after his official retirement from the Geological Survey (as Chief Palaeontologist) in 1952 He brought a sound objective judgement to the study of the systematics and biostratigraphy of New Zealand Bivalvia and Gastropoda. His revisions (illustrated by his own pen and ink drawings) of Struthiolariidae, Naticidae, Volutidae, Veneridae, Cardiidae and his monographs of Tertiary faunas, notably the Danian (Palaeocene) Wangaloan fauna, described jointly with the late Dr H J. Finlay, earned John Marwick a world reputation as a student of fossil Mollusca

With his colleague Finlay, who pioneered study of New Zealand Cretaceous and Cenozoic Foraminifera at the Geological Survey, Marwick was also responsible for defining and improving the standard sequence of local biostratigraphic stages that have been of great value in geological mapping in New Zealand As a primarily Cenozoic palaeontologist, he regarded his occasional deviations into the Mesozoic as somewhat amateurish, yet his contributions include a standard reference work on New Zealand Triassic and Jurassic fossils On the other hand he welcomed field work in a Geological Survey faced by the hard times and stringencies of the great economic depression, when Marwick was expected to assist in geological mapping and writing diverse reports with little relevance to palaeontology He gained great satisfaction from descriptive geomorphology and stratigraphy, so that his publications in these subjects, for instance on the physiography and structure of the Rotorua–Taupo volcanic zone (with H.E. Fyfe) and on the geology of Te Kuiti district must always rank high among his achievements.

Dr Marwick might well have become Director of the Geological Survey, but although he served as Acting-Director on occasion, he preferred to remain in his palaeontology laboratory. On several occasions he lectured in geology at Victoria University of Wellington (then a college of the University of New Zealand) when his close friend Dr C. A. Cotton (later Sir Charles), well known for his geomorphology text books, was overseas on sabbatical leave; and he also served as external examiner for higher degrees He took an active part in the Royal Society of New Zealand, which had awarded him the Hamilton Prize for beginners in science (1926) and elected him a Fellow in 1935; he was awarded both the Hector and the Hutton Memorial Medals of the Society for his contributions to palaeontology. He served on Council, was Honorary Editor of the Society's *Transactions* (1938–46) and was elected Vice-President (1950–52) but declined nomination as President.

Especially during the search for petroleum in New Zealand between the wars and after 1945, Marwick introduced many overseas geologists to New Zealand stratigraphy and he recalled with pleasure his excursions to fossil localities with Drs T. Wayland Vaughan, Axel A. Olsson, F. A. Singleton, and other visiting palaeontologists.

Jack Marwick was an unselfish man of high integrity, whose humanity and altruism made him a father figure to the many young geologists he helped in their careers; while his sincerity, good humour, and broad-based culture earned the friendship and respect of his colleagues.

C. A. Fleming

A Textbook of Human Anatomy

EDITED BY W. J. HAMILTON

The new edition of this well-known and widely used textbook has been completely revised in order to bring it up-to-date with recent advances in fields of medicine such as immunology.

The number of illustrations has been considerably increased and includes some excellent four colour plates.

The format of the book has been enlarged and the layout clarified.

Price £14.50 768 pages ISBN 0 333 18115 8

Human Embryology

HAMILTON, BOYD AND MOSSMAN

Fourth Edition revised by
W. J. Hamilton and H. W. Mossman

This classic text has been the standard authority since it was first published in 1945.

In its revised form the fourth edition contains several new sections including a chapter on the development, structure and functional activities of the placenta and a large number of new micrographs

Such a book will be an essential reference work for medical students, research workers clinicians and surgeons.

'This finely produced and scholarly book will remain the definitive English text for many years'
British Medical Journal

£16.00 ISBN 0 333 19153 6

The Human Placenta

BOYD AND HAMILTON

'The production of this book is a publishing event of importance. Two of the most distinguished anatomists with a special interest in the human placenta have combined, as often they have before, to write and of course illustrate a classic . . . Of course the book is expensive. Such a lavish feast of riches, the product of a lifetime's work and thought allied with the best of the publisher's art, could scarcely be otherwise. No department of anatomy, of obstetrics and gynaecology, of reproductive physiology, or of endocrinology, can consider its library complete without possessing a copy of this elegant informative volume'
Philip Rhodes *British Medical Journal*

£25.00 ISBN 0 333 19186 2

Surface & Radiological Anatomy

For students and General Practitioners

Fifth Edition

HAMILTON, SIMON AND HAMILTON

Increasing emphasis is now being given to the study of anatomical structures which are accessible to examination in the living subject and this beautifully produced book answers a need for an authoritative text on the subject.

In this fifth edition several changes have been made, many of the original micrographs have been replaced.

'The editorial trinity have established a wonderful text; the association of an anatomist, a radiologist and a surgeon seems to be ideal'
The British Journal of Surgery

£9.50 ISBN 0 333 19154 4

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of

GRADUATE RESEARCH ASSISTANT

(1 year contract) jointly in the DEPARTMENT OF APPLIED MATHEMATICS AND ASTRONOMY and the DEPARTMENT OF BIOCHEMISTRY. Duties to commence as soon as possible.

The post is suitable for a graduate in Chemistry, Biochemistry or related discipline and the work will be in collaboration with Dr A H. Olavesen, Sir Fred Hoyle and Professor N. C Wickramasinghe on Laboratory Studies of the Infrared Spectra of Interstellar Polymers.

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P O. Box 78, Cardiff CF1 1XL. Closing date January 31, 1979 Please quote reference 1644. 8549(A)

ROTHAMSTED EXPERIMENTAL STATION

Harpenden, Herts. AL5 2JQ

SENIOR PRINCIPAL SCIENTIFIC OFFICER

to assist in the supervision of work in the Soils and Plant Nutrition Department, especially of projects with a physico-chemical or mathematical bias

Qualifications should include a good basic training in physical chemistry or other physical science, with a distinguished record of work in a topic related to soil science.

Appointment in the grade of Senior Principal Scientific Officer on a scale rising by two annual increments from £10,043 to £11,300 p.a. Non-contributory superannuation

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref 364 by December 22, 1978. Further details on request. 8547(A)

POSTDOCTORAL POSITION

in development of field desorption double focusing mass spectrometry and associated techniques, and applications to studies of polar, labile biological substances. Experience in physical, instrumental and computer aspects as well as working knowledge of structural studies in bio-organic chemistry necessary. Position available for 1 year with possibility for renewal based upon performance Salary $11,880 to 14,916 Send curriculum vitae, names of three references and reprints/preprints to: Dr A L Burlingame, Biomedical Mass Spectrometry Resource, Space Sciences Laboratory, University of California, Berkeley, Ca. 94720. The University of California is an Equal Opportunity Employer. 8537(A)

INSTITUTE OF TERRESTRIAL ECOLOGY

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

CHEMIST

A chemist at Higher Scientific Officer/Senior Scientific Officer level is required to join a team concerned with research on the fate and effects of atmospheric pollutants. The team, which is studying forest ecosystems, needs a greater understanding of chemical events occurring on leaf surfaces, including surface exchange processes and the release of foliar leachates.

The successful applicant will be based at the Institute's Bush Estate Station, seven miles south of Edinburgh.

Qualifications

Candidates should possess a good 1st or 2nd class honours degree or its equivalent in chemistry and have at least two years' post graduate research experience. A specialist interest in physical chemistry or biochemistry would be an advantage.

Salary and Conditions of Service

The salary will be within the following scales.

H.S.O. £4,101 to £5,448 per annum; S.S.O. £5,154 to £6,898 per annum with 22 days paid annual leave plus 10½ days Public and Privilege holidays

Starting pay according to age, qualifications and experience.

There is a non-contributory superannuation scheme.

The Natural Environment Research Council is not a Government Department but conditions of service are similar to those of the Civil Service.

Application forms and further details are available from:

Establishments Section
Institute of Terrestrial Ecology
68 Hills Road
Cambridge
CB2 1LA (0223 69745)

Closing date for completed applications is December 8, 1978.

Please quote reference 363.

8511(A)

EAST MALLING RESEARCH STATION

FRUIT BREEDING DEPARTMENT

PLAN BREEDER/ GENETICIST

to join team breeding new varieties of fruit crops.

Applications are invited from graduates with First or Upper Second Class Honours degree in Botany with Plant Genetics.

Appointment Scientific Officer grade (£2,839 to £4,415) or Higher Scientific Officer grade (£4,101 to £5,448), at least two years post qualifying experience is required for appointment as Higher Scientific Officer.

Details and application form from Assistant to the Secretary, East Malling Research Station, East Malling, Maidstone, Kent ME19 6BJ. 8535(A)

INSTITUTE OF TERRESTRIAL ECOLOGY

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

EXPERIMENTAL PLANT ECOLOGIST

An experimental plant ecologist at Higher Scientific/Senior Scientific Officer level is required at the Institute's station at Bangor, Gwynedd. He/She will be expected to work with other scientific staff stimulating additional interest in a programme of vegetation management with grazing animals

Qualifications

Applicants should have a good 1st or 2nd honours degree or equivalent in agriculture ecology or a related biological subject and at least 2 years postgraduate research experience showing proficiency in quantitative ecology.

Salary and conditions of service

The salary will be within the following scales:

H S.O. £4,101 to £5,448 per annum
S S O. £5,154 to £6,898 per annum

with 22 days paid annual leave plus 10½ days Public and Privilege holidays

Starting pay according to age, qualifications and experience. There is a non-contributory superannuation scheme

The Natural Environment Research Council is not a Government Department but conditions of service are similar to those of the Civil Service.

Application forms and further details are available from:-

Establishments Section
Institute of Terrestrial Ecology
68 Hills Road
Cambridge

Closing date for applications: December 8, 1978.

NATURAL ENVIRONMENT RESEARCH COUNCIL

8508(A)

ICI/UNIVERSITY OF LEICESTER

Joint Laboratory in Molecular Genetics

The above laboratory has vacancies for experienced post-doctoral molecular biologists and microbial geneticists and for grade 3 to grade 6 laboratory technicians to work:

(i) in the field of eukaryotic gene expression in prokaryotes, and
(ii) on the genetics and related biochemistry of the methylotrophs.

Appointments will be made for periods of up to 5 years, with salaries in the range:

£3,883 to £6,555 for post-doctoral Research Associates and £2,688 to £4,365 for technicians.

Salary scales are currently under review.

Applicants should send a detailed curriculum vitae and names of two references to both:

Professor W. J. Brammar,
Department of Biochemistry,
University of Leicester,
University Road,
Leicester LE1 7RH

and

Bioscience Group,
ICI Corporate Laboratory,
P.O. Box 11,
The Heath, Runcorn,
Cheshire WA7 4QE

8528(A)

Senior Scientist Metabolic Studies

This appointment within the Drug Metabolism section of our Research Department based in Nottingham, arises from internal promotion

It calls for someone capable of directing an established team and to be responsible for all in-vitro and in-vivo metabolic studies in animals and man, using radio-tracer techniques to investigate absorption, disposition and biological transformation of compounds intended for use in human medicine. The work also involves collaboration with staff working in other areas of the Research Department so the ability to communicate effectively is required

Candidates (men or women) must be graduates in biochemistry, chemistry or an allied scientific discipline and hold a higher degree in an appropriate field of research. Several years' experience in drug metabolism studies including extensive use of radio labelled compounds is essential.

Benefits include a profit sharing scheme and staff purchase privileges. Generous help with relocation to the area is available

Please write for an application form to. T. W. Flower, Employment Manager (Technical),

The Boots Company Limited,
Station Street, Nottingham, NG2 3AA.

8559(A)

MEAT RESEARCH INSTITUTE

PUBLIC RELATIONS OFFICER

A scientist of wide interests with a flair for communications work is required to present the research activities of the Institute to the world at large.

The preparation of a variety of articles for publication in journals, trade magazines and the popular press, assistance in the production of radio and television programmes, and organisation of exhibitions are a few examples of the range of duties In addition, the successful applicant will have a supervisory responsibility for the library service and for reception of visitors Further details are available on application

Qualifications: Science degree, H N C. or equivalent qualification with relevant experience or an honours degree. At least 5 years' relevant post-qualifying experience is required for appointment as H.S O Evidence of ability to write good English will be required. A knowledge of French and/or German would be an advantage.

Salary: S.O grade (£2,839 to £4,415) or H.S.O grade (£4,101 to £5,448), starting salary depending on experience.

Non contributory superannuation.

Closing date for applications: December 7, 1978

Application forms and further details obtainable from:

Personnel Officer
Meat Research Institute
Langford
Bristol
BS18 7DY.

8514(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of

SENIOR LECTURER

in the DEPARTMENT OF BOTANY.

Applicants should be qualified in any of the following disciplines of Genetics: Molecular Genetics, Population Genetics and Quantitative Genetics. In addition candidates must have a Ph D. in Botany with extensive teaching and research experience as evidenced by published work. The appointee will be expected to take part in the teaching of both undergraduate and postgraduate courses and to develop vigorous research programmes in his/her areas of specialisation. Further details may be obtained from the Chairman of the Department. Salary K£2,988 to £3,984 p.a. (K£1=£1 36 sterling). The British Government may supplement salary by £4,770 p a (sterling) for married appointee or £3,252 p a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages, S S.S.F. or F.S.S.U ; non-contributory medical scheme, subsidised housing/housing allowance

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar (Recruitment and Training) University of Nairobi, P.O Box 30197, Nairobi, Kenya, by December 21, 1978. Applicants resident in the U.K should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

8558(A)

UNIVERSITY OF SURREY

DEPARTMENT OF HUMAN BIOLOGY AND HEALTH

EXPERIENCED TECHNICIANS GRADE 5

(£3,186 to £3,720) under review

Due to an expansion we require qualified and experienced technicians to join our existing team of twelve. The Department runs undergraduate courses in Human Biology and in Nursing Studies. The laboratories teach physiology, anatomy and related subjects in human biology The technicians will help with class preparation and also assist in one of the following areas of research:

- Neurophysiology, both human and animal
- Environmental physiology, using a new environmental chamber
- Biochemical and immunological research
- Studies of factors affecting human performance.

If you have an H N.C. in Applied Biology, Advanced City & Guilds Laboratory Technicians Certificate or similar, and have several years' laboratory experience (even if not directly in the above fields) we would like to hear from you

The department is in a new building in attractive surroundings, adjacent to an historic town with excellent recreational facilities on the campus and in the surrounding area

Further particulars and application forms for the posts may be obtained from the Staff Officer, University of Surrey, Guildford, Surrey GU2 5XH or telephone Guildford 71281, ext 452.

8572(A)

INSTITUTE OF TERRESTRIAL ECOLOG

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

RADIO-CHEMIST

A radio-chemist is required, Higher Scientific Officer/Senior Sc tific Officer level, to work in conj tion with ecologists on the reten and movement of radionuclides semi-natural terrestrial ecosystems.

Applicants will be expected to ticipate in the planning of the resea programmes, data assessment and paration of reports in co-operat with the ecological staff.

The successful officer will be be at the Institute's Merlewood Resea Station, Grange over Sands, Cumbr

Qualifications and experience

Candidates should possess a 1st 2nd class honours degree or equiva in Chemistry, Physics or related ject and have at least two years' r vant post graduate experience.

Salary/conditions of service

Starting salary according to qualifications and experience on following scale

£4,101 to £6,898 per annum with days paid annual leave plus 10½ Public and Privilege holidays Ther a non-contributory superannua scheme.

The Natural Environment Resea Council is not a Government Dep ment but conditions of service similar to those of the Civil Servic

BERKELEY PHYSICS

The Physics Department of the Uni- rsity of California, Berkeley, expects ring the next two years to be mak- g one or two appointments at the sistant professor level. Preferred areas research are astrophysics, atomic d plasma physics, condensed matter ysics, nuclear physics, and particle ysics, with some priority given to eoretical condensed matter physics, perimental plasma physics, and eoretical particle physics.

Applicants should write before ebruary 1, 1979, to the **Chairman of e Physics Department, University of alifornia, Berkeley, CA 94720, USA,** ving curriculum vitae, publication st, and references. The University of alifornia is an Affirmative Action mployer. 8569(A)

AGRICULTURAL RESEARCH COUNCIL

LETCOMBE LABORATORY

Scientific Officer/Higher Scientific fficer required in the Soil Atmos- ere and Nitrogen Section of the eld Studies Department of Letcombe boratory.

The Section is concerned with the te of nitrogen fertilizer and factors ecting its uses for grasslands and real crops under a range of cultiva- n techniques. The officer appointed ll be responsible for planning and ecuting part of this research and r the development of new experi- ental approaches to understanding e fate of nitrogen fertilizer.

Minimum qualifications: First or per second class honours degree or equivalent qualification with at st two years relevant post qualifying perience for appointment at the gher grade.

Salary scale for Scientific Officer ,839 to £4,415 and Higher Scientific ficer £4,101 to £5,448. Non- ntributory superannuation scheme.

Appointment at Senior Scientific ficer (£5,154 to £6,898) level would considered for an exceptionally well alified candidate.

Application forms and further tails from The Secretary, Agricul- al Research Council, Letcombe boratory, Wantage, Oxon OX12 T by December 7, 1978. 8515(A)

Central Birmingham Health District

IRMINGHAM MATERNITY HOSPITAL

CYTOGENETICIST

Trere is an immediate vacancy for experienced Cytogeneticist (Basic ade Scientific Officer) in the Infant velopment Unit at the above hos- al. The laboratory is one of two ponsible for the service needs in West Midlands Region. There is taff of four full time Cytogeneticists, ticipating in all aspects of the work there is a possibility of promotion. plicants should hold a relevant ence degree.

Salary scale £3,486 rising to a ximum of £4,899.

Visits to the laboratory may be anged by appointment with Dr meron, Tel 021-454 4851, Ext. 224 ildrens' Hospital).

Application forms and job descrip- ns from Personnel Officer, Birming- n Maternity Hospital, Edgbaston, mingham B15 2TG. Tel 021-472 7. 8554(A)

UNIOR TECHNICIAN required in Division of Molecular Biology at Institute of Cancer Research boratory, Fulham Road, London 3, to assist with work on the pro- s of the genetic material. Candi- es should have at least two 'A' els in Chemistry, Physics, Maths or logy. The appointment is for a ee year period initially. Salary in le £2,169 per annum to £3,015 per um according to age and qualifi- ions, plus London Allowance of 4 per annum. Applications in dupli- e with the names of two referees to Secretary, Institute of Cancer earch, 34 Sumner Place, London 7 3NU, quoting ref. 301/B/55. 8527(A)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

CLINICAL SCIENCES BUILDING,
ROYAL FREE HOSPITAL,
HAMPSTEAD, LONDON

SENIOR LECTURESHIP IN PHYSIOLOGY

Applications are invited for the above post which is available from January 1, 1979. Duties will include teaching and research. The Department of Physiology is now housed in new premises in Hampstead which are integral with the Royal Free Hospital, giving improved facilities for joint work and cooperation with clinical departments. All departmental activities take place in the new premises except for occasional lectures and meetings in the Hunter Street section of the School. Medical qualifications will be an advantage but are not essential. Salary will be on the preclinical scale in the range £7,506 to £9,263 plus £450 London Allowance.

Arrangements to visit the department should be made directly with Professor C. B. B. Downman (tel. 01-794 0500, ext. 4301). 6 copies of applications (preferably typewritten) giving full details with names and addresses of two referees should be sent by December 15, 1978 to the Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP, from whom further particulars may be obtained. 8543(A)

HOUGHTON POULTRY RESEARCH STATION

GENETICIST

A vacancy exists in the Leukosis Experimental Unit for a geneticist to study the inheritance and nature of resistance of chickens to oncogenic and other viruses, and to assist in the formulation of breeding programmes for the Institute's flocks.

Applicants must have a first or upper second class honours degree, with genetics as a major subject in the first or a higher degree, and preferably a Ph.D. or at least 3 years' relevant postgraduate experience. A minimum of 4 years' relevant postgraduate experience is required for the S.S.O. grade.

The appointment will be to the Higher Scientific Officer grade (£4,101 by 8 to £5,448) or the Senior Scientific Officer grade (£5,154 by 8 to £6,898), grade and starting salary depending upon experience. Non-contributory superannuation scheme.

Further particulars and application forms from the Station Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs. PE17 2DA. Closing date for applications is January 10, 1979. 8507(A)

UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT

Applications are invited for the position of Research Assistant to work upon the catabolism of abnormal haemoglobins in rabbit reticulocytes and erythrocytes. The post is available for three years, financed by a grant from the Wellcome Trust and the salary will be £3,384 per annum plus £450 per annum London Allowance, with annual increments on the scale £3,384 to £3,883 per annum, plus £450 per annum London Allowance. Universities Superannuation Scheme contributions would be payable.

Candidates should have a good Honours Degree in biochemistry or a related subject and research experience.

Applications, together with the names of two referees, should be sent to Dr A. R. Hipkiss, Department of Biochemistry, Strand, London WC2R 2LS to reach him no later than Friday, December 1, 1978 quoting reference **191652/N.** 8540(A)

There is a vacancy for a BIOLOGIST in *Nature's* London office. He or she would join the team which assesses the suitability of biological manuscripts for publication; there would also be opportunities to work with members of the *Nature* staff in compiling other sections of the journal. The job might appeal to the holder either of a bachelor's or an advanced degree.

Science Group
CIVIL SERVICE

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF PSYCHIATRY

A Technician (Grade 4) is required for full-time duties in the Department of Psychiatry, Stopford Building (New Medical School). The successful applicant will work with a small research team studying the effects of drugs on the central nervous system. Duties will include assistance with electrophysiological experiments, photography and general laboratory maintenance. Some knowledge of electronics is an advantage.

The applicant should possess H.N.D. or H.N.C. (or equivalent qualifications) in appropriate subjects and have several years' relevant laboratory experience.

Salary range £2,955 to £3,402 per annum (scale under review).

Consideration will be given for appointment to a lower graded post to candidates possessing an O.N.C. or equivalent qualification.

Applications, together with a curriculum vitae and the names and addresses of two referees, should be sent to Mrs G. Scott, Department of Psychiatry, University Hospital of South Manchester, West Didsbury, Manchester M20 8LR. Closing date for applications, December 8, 1978.

8517(A)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF CHEMISTRY

Applications are invited for a research post to study the use of coherent Raman spectroscopy in combustion. The work will be carried out initially at Southampton University and could lead to a permanent position at Rolls Royce. Applicants should possess a Ph.D. (or in exceptional cases a first degree) and have experience in one or more of the following fields:- laser, combustion, spectroscopy. Applicants with a first degree only will be expected to register for a higher degree. A high degree of experimental ability is desirable. Salary for a research fellowship up to £4,382 per annum. Alternatively for a research studentship, a grant of £1,610 is payable.

Please apply in writing giving curriculum vitae etc., and the names of two referees to Professor I. R. Beattie, Chemistry Department, The University, Highfield, Southampton Hants. SO9 5NH. Please quote ref: MAI/Z/**Na.**

8516(A)

UNIVERSITY OF OXFORD
UNIVERSITY LECTURESHIP IN ELEMENTARY PARTICLE PHYSICS

Applications are invited for the above post. Stipend according to age on the scale (under review) £3,883 to £8,257. The successful candidate may be offered a tutorial fellowship by Balliol College (for either a man or a woman). Details of both appointments may be obtained from Professor K. W. Allen, Department of Nuclear Physics, Keble Road, Oxford OX1 3RH, to whom completed applications (one typed copy) and the names of three referees should be sent by January 31, 1979.

8506(A)

RESEARCH TECHNICIAN for Department of Anatomy to assist group in study of the development of lymphocytes. Extensive tissue culture and use of a variety of immunological techniques are involved. Previous experience and appropriate qualifications essential. Instruction will be given in techniques related to tissue culture and immunology. Salary scale £2,955 to £3,402 per annum. Ref. 401/C/327. Application form from Assistant Secretary, Personnel Office, University of Birmingham, P.O. Box 363, Birmingham B15 2TT.

8529(A)

UNIVERSITY OF NEWCASTLE UPON TYN
DEPARTMENT OF SOIL SCIENCE

Applications are invited for a ne established Lectureship in the Depa ment of Soil Science to take appointment as soon as possible. Ap cants should be qualified to teach the soil chemistry and fertility sect of the subject. Those applicants w special interests *either* in the natı and properties of inorganic/orga soil colloid surfaces *or* in experimen design and data processing may preferred.

Salary will be at an appropri point on the Lecturers' scale: £3, to £7,754 per annum, according to a qualifications and experience. Memb ship of the appropriate Univers superannuation scheme will be quired.

Further particulars may be obtair from the Registrar, The Universi Newcastle upon Tyne NE1 7RU, w whom applications (three copi together with the names and addres of three referees, should be lodged later than January 1, 1979. Ple quote reference N.

8524(A

UNIVERSITY OF WARWIC
SENIOR RESEARCH TECHNICIAN

In the Department of Biologi Sciences, to organise the daily runni of the technical services of the Chlo plast Research Group, and to as with research under the personal dir tion of Professor R. J. Ellis. T research programme is aimed at ravelling molecular interactions tween the nuclear and chloropl genomes. The main techniques u include *in vitro* protein synthesis isolated chloroplasts and wheat ge extracts programmed with mRNA, the analysis of RNA and polypepti by one and two-dimensional polyac lamide gel electrophoresis. Appli tions are invited from suitably qualif persons with several years' experie in biochemistry. Salary on the Te nician Grade 5 scale £3,186 to £3, per annum (under review). Ref. 15/D/78.

RESEARCH TECHNICIAN

The Department of Biologi Sciences has vacancies in the Chlo plast and Developmental Biology search Groups. The work involves isolation and characterisation of p teins and nucleic acids, using stand biochemical techniques. The posts for contract periods of one to th years. Applications are invited fr graduates and others with appropri qualifications in biochemistry and microbiology. Salary either on Technician Grade 2B scale: £2,529 £2,880 per annum *or* Grade 3 £2, to £3,060 per annum (under revie Ref. No: 15/2D/78.

Applications (n/f), for the ab posts should be made by letter quot the appropriate Ref. No. and giv full details to the Personnel Offi University of Warwick, Coventry C 7AL. Closing date for receipt applications is November 30, 1978.

UNIVERSITY OF CALIFORNIA
SANTA CRUZ
BOARD OF STUDIES IN ASTRONOMY AND ASTROPHYSICS AND STEVENSON COLLEGE

Applications are invited for the position of:

ASSISTANT PROFESSOR OF ASTROPHYSICS

effective September 1, 1979

Appointee will have graduate and ıdergraduate teaching and advising sponsibilities, will be expected to ount a research program in the oard, and to participate on the aca- :mic and intellectual life of the ollege. Position is in regular tenure- ack series; initial appointment is for vo years. Applicants must hold Ph.D. expect to receive it by September 1979.

Persons active in theoretical astro- ıysics with interests in a broad ıriety of problems, and who would elcome the opportunity of interaction ith astrophysicists, physicists and ick Observatory astronomers, and ho have a strong commitment to aching are preferred. Applications om non-optical, non-IR observational stronomers who have a strong theor- ical component to their research iterests will also be considered.

Salary, $15,100 to $15,700, nine onth basis. Applicant should send ırriculum vitae, list of publications, atement of research interests and aching experience, together with ımes of at least three references who ıve been asked to submit letters of commendations directly to us. All ıpporting materials should be sent, med to arrive not later than January 5, 1979, to:

Dr Robert P. Kraft, Chair
Board of Studies in Astronomy
and Astrophysics
Lick Observatory
University of California
Santa Cruz, CA 95064
(An Affirmation Action/Equal
Opportunity Employer)

'HE UNIVERSITY OF HULL
SENIOR LECTURER/ LECTURER IN APPLIED PHYSICS

Applications are invited for the post Senior Lecturer/Lecturer in the epartment of Applied Physics for ork on satellite laser ranging, tenable om a date to be arranged.

Salary scale: £3,883 to £9,263 per ınum (under review) plus superannu- ion benefits.

Applications (six copies) giving tails of age, qualifications and ex- rience, together with the names of ree referees, should be sent by ecember 4, 1978 to the Registrar, ıe University of Hull, Hull HU6 :X from whom further particulars ay be obtained. 8526(A)

Applications are invited for a

FACULTY POSITION IN ZOOLOGY

beginning September 1, 1979. Candidates are sought at, but not restricted to, the Assistant Professor level. Applicants should have a research background in structural–functional relationships at analytical ultrastructural, physiological, and biochemical levels, with emphasis on such areas as cell–cell interactions, cell motility, cell surface phenomena and/or membranes. Applicants should have sufficient breadth to be able to contribute to undergraduate teaching at the organismal level, as well as in their specialty.

Send application letter, statement of research plans, curriculum vitae, including teaching and funding experience, sample reprints, and names of five referees to: Dr A. G. Jacobson, Department of Zoology, University of Texas at Austin, Austin, Texas 78712.

Application deadline: December 15, 1978.

An equal opportunity/affirmative action employer. 8497(A)

M.I.T.
Postdoctoral and Predoctoral Research Positions

Several positions are available for research in genetic toxicology with emphasis on mechanisms of chemical mutation of human cells. Strong background in chemistry is desired of predoctoral researchers, and molecular biology of postdoctoral researchers. Please send resumes to Professor William G. Thilly, Room E18-666, M.I.T., Cambridge, MA 02139. M.I.T. is an equal opportunity employer.

8392(A)

SIMON FRASER UNIVERSITY
BRITISH COLUMBIA, CANADA
DEPARTMENT OF BIOLOGICAL SCIENCES
ENTOMOLOGIST

The Department of Biological Sciences invites applications for a tenure track position in entomology. The successful applicant will be expected to develop a strong research programme and to participate in the teaching programme at both the undergraduate and graduate level including courses in the Master of Pest Management Programme. Candidate must have a Ph.D. degree in entomology or related subjects; preference may be given to individuals with teaching and research experience in agricultural pest management. The position is available, subject to budgetary constraints, from September 1, 1979. The initial appointment is for a period of two years, renewable. Salary will depend on experience; the base salary for the Assistant Professor rank currently is $18,604 per annum.

Applications, including an up-to-date curriculum vitae, reprints of published research, and the names of three referees should be sent to: Dr M. Mackauer, Chairman, Department of Biological Sciences, Simon Fraser University, Burnaby, B.C., Canada, V5A 1S6. Deadline for receipt of applications is January 31, 1979 or when position filled. 8390(A)

OXFORD UNIVERSITY
UNIVERSITY LECTURESHIP IN EXPERIMENTAL PHYSICS

Applications are invited for a University Lecturership in Experimental Physics in the Clarendon Laboratory (which may be held in association with an Official Tutorial Fellowship at Worcester College). Preference will be given to candidates whose research is in the general field of atomic and radiation physics.

Further particulars may be obtained from Professor E. W. J. Mitchell, The Clarendon Laboratory, Parks Road, Oxford OX1 3PU, to whom applications should be sent by December 15, 1978. 8522(A)

Solomon Islands
Senior Forestry Officer
Up to £9,200 plus allowances

Candidates should have a degree or diploma in Forestry with relevant management and work study experience, preferably in the tropics.

The work will involve general forestry duties including surveys, co-ordinating costs and records at field stations, and training local staff.

Salary includes a substantial tax-free allowance paid under Britain's overseas aid programme. Basic salary attracts 25% tax-free gratuity.

Benefits include free passages, generous paid leave, children's holiday visit passages and education allowances, outfit allowance, subsidised housing, appointment grant and interest-free car loan.

The terms on which civil and public servants may be released if selected for appointment will be subject to agreement with their present employers.

For full details and application form write quoting MD/1036/NA.

Research Biochemist

Roche Products Limited is part of a major international pharmaceutical Company based in Switzerland and is itself one of the leaders of the industry in the United Kingdom.

We currently have a vacancy for a Research Biochemist, male or female, in our Biochemistry Department, part of a multi-disciplinary Research Function based at Welwyn Garden City. The work involves investigating novel antithrombotic and antihypertensive agents.

Applications are invited from those with B.Sc. (or equivalent) in Biochemistry/Pharmacology and several years' research experience in the cardiovascular area. A knowledge of haemotology and/or lipid biochemistry is desirable.

Our Biochemistry Department is located in modern laboratories where the working conditions and facilities are excellent. Conditions of Service include a Christmas Award, 4 weeks' annual holiday, free life assurance and BUPA membership, contributory pension fund and subsidised restaurant.

If you would like to apply for this post, please write briefly or telephone for an application form (Welwyn Garden 28128) to Mrs Clewley, Research Personnel Department, quoting reference RB30. Roche Products Limited, P.O. Box 8, Welwyn Garden City, Herts AL7 3AY.

8574(A)

ROCHE

Plant Pathologists/ Fungal Physiologist

Shell Research Limited is seeking two plant pathologists, one of whom could be a Fungal Physiologist, to join the reseach staff of Shell Biosciences Laboratory at Sittingbourne, Kent.

One of the posts is in the Fungicides Section of the Biological Evaluation Division where you should have a good background in plant pathology, probably to Ph.D. level, together with an understanding of the principles of crop protection. Whilst the work will entail the evaluation of new fungicides at several stages, it is anticipated that you will be capable of assuming responsibility for a major share of the field development programmes in the UK and overseas. An ability to present good written reports is essential.

The other post (Fungal Physiologist) is within the Plant group of our Physiology and Biological Chemistry Division where you will be responsible for initiating and conducting research projects on a biochemical/physiological level, in areas of plant pathology, mycology or fungicide mode of action. You should have a good first degree and research experience in plant pathology or mycology.

For either post you should be aged between 24-29 years. We offer a competitive salary and assistance will be given with relocation expenses where appropriate. You will be able to join our pension fund, enjoy flexible working hours and work in well-equipped laboratories which are situated on a 450 acre farmland site. There are also excellent facilities for sports and social activities. Please write giving all the relevant details about yourself and your career or telephone for an application form to:

Shell Research Limited, Recruitment Division PNEL/11 (N1), Shell Centre, London SE1 7NA. Telephone: 01-934 2948.

CSIRO

AUSTRALIA

Research Scientist/ Postdoctoral Research Fellow

(2 Positions)

Division of Atmospheric Physics Aspendale, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Dynamical Meteorology/Dynamical Oceanography

General: The Division of Atmospheric Physics is engaged in research in three broad areas: Dynamical Meteorology, Radiation and Climate and Atmospheric Chemistry. The Dynamical Meteorology programme comprises individual research projects on a variety of topics including large scale atmospheric circulations, the dynamics of stratified and rotating fluids, convection, mixing and entrainment, the atmospheric boundary layer and air/surface interaction. The programme also includes studies on the effects of regional and topographic factors on weather and climate and the circulations in the waters surrounding Australia.

Wherever possible the approach to these topics combines analytical, numerical and laboratory modelling techniques, and field experiments. The Division has an active and well equipped geophysical modelling laboratory and, in addition to local computers, has access to the CSIRO's CYBER network. Interaction with the Australian Government Bureau of Meteorology, the Australian Numerical Meteorology Research Centre and the CSIRO Divisions of Cloud Physics and of Fisheries and Oceanography is encouraged.

Duties: To conduct appropriate theoretical and experimental research on topics concerning the large scale dynamics of the atmosphere or dynamical oceanography relevant to the southern hemisphere weather and climate.

Qualifications: Applicants should have a strong background in geophysical fluid dynamics and a Ph.D. or equivalent qualification, and postdoctoral experience demonstrating a high level of ability in self-motivated and original research.

Salary: Research Scientist or Senior Research Scientist: $A14,829—$A21,543 p.a. Outstandingly qualified scientists should not be deterred from applying as appointment at a higher level would be considered.

Tenure: One appointment will be of indefinite tenure. For the other either an indefinite or a fixed term appointment may be negotiated. Both carry superannuation benefits.

Applications **in duplicate**, stating **full** personal and professional details, the names and addresses of at least two professional referees, and **quoting reference number 420/352** should reach:—The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, London WC2R 3EH by 22nd December 1978.

Applications in U.S.A. and Canada should be sent to:—The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 8552(A)

AN FORAS TALUNTAIS

GRADUATE IN CHEMISTRY, BIOCHEMISTRY, OR FOOD SCIENCE

required for research on quality aspects of fresh and processed horticultural crops at Kinsealy Research Centre, Malahide Road, Dublin 5. **Essential:** Honours University degree or equivalent majoring in Chemistry, Biochemistry or Food Science. **Desirable:** Suitable research experience.

Appointment up to and including Senior Research Officer level (salary scale £6,459 to £8,465 p.a.) depending on qualifications and experience Non-contributory pension scheme with provision for Widows' and Orphans' Pensions.

Application forms and further particulars from the Personnel Department, An Foras Taluntais, Headquarters, 19 Sandymount Ave., Dublin 4, Tel: 01-688188. Latest date for receipt of completed forms: Friday. December 15, 1978. 8518(A)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF MICROBIOLOGY

Applications are invited from men and women for the following post financed by S R.C, tenable for 3 years from a date as soon as possible to be arranged· Postdoctoral research assistant to work on the mechanism of methanol assimilation in yeasts, involving isotopic work with whole cells and purification and study of enzymes Applicants should possess, or expect soon to possess a Ph D in microbiology or biochemistry. Salary up to £4,382 a year on Range IA. Particulars from Professor J. R Quayle in the above Department to whom applications, quoting two referees, should be sent by December 11, 1978. UNIVERSITY OF DUNDEE
DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

There is an immediate vacancy in the above Department, based at Ninewells Hospital and Medical School, Dundee, **for a**

RESEARCH TECHNICIAN

to join a group engaged in a study of 'oncofetal proteins.

Experience of protein purification techniques and radioimmunoassay is desirable though not essential.

An applicant with an appropriate H.N.C. or equivalent qualification and at least eight years relevant experience would be eligible for appointment at a salary of up to £3,720 per annum but an appointment at a lower grade could be offered to a less well-qualified and experienced applicant.

Applications, giving details of qualifications and experience and the names of two referees should be sent to The Secretary, The University, Dundee DD1 **4HN** by **December** 7, 1978. Please quote Ref: EST/170/78J.

8531(A)

LABORATORY Scientific Officer required from March 1, 1979 for work on a three-year research project, supported by the Medical Research Council, examining the effect of steroids on experimental and human immune complex disease. Techniques used will include basic immunochemical methods, analytical ultracentrifugation, tests of macrophage function and electron microscopy. Salary for qualified Laboratory Scientific Officer not less than £3,261 plus £354 London Weighting. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. R.U.I.

8545(A)

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF BOTANY

Position immediately available as

EXPERIMENTAL OFFICER

in the A.R.C. Group working on the fusion of plant protoplasts. Appointment for one year in the first instance. Applicants should possess a degree, preferably in the biological sciences. Salary scale (£3,384, £3,634, £3,883).

Applications to Professor E. C. Cocking, Department of Botany, University of Nottingham, University Park, Nottingham NG7 2RD.

8525(A)

UNIVERSITY OF BRISTOL
MATHEMATICAL STATISTICS

Applications are invited
from probablists and statisticians
for the post of

LECTURER IN STATISTICS

in the School of Mathematics.

The person appointed will have the responsibility for teaching undergraduates in a combined mathematics and statistics degree programme and for supervising the research of postgraduate students in Probability and Statistics. Personal research interests should lie in the same fields.

The post is tenable from August 1, 1979 **and the** initial salary will be within the range £3,883 to £6,317 per annum on the current salary scale for Lecturers.

Further particulars may be obtained from the Secretary, University Senate House, Tyndall Avenue, Bristol BS8 1TH, **to whom** applications should be sent by December 15, 1978 (please quote reference EB).

8502(A)

APPTS. VACANT CONT'D.

QUALIFIED Laboratory Scientific Officer required in Physiology Department, to assist with teaching laboratory duties and research. Salary not less than £3,261 on scale rising to £4,680, plus £354 London Weighting. Apply in writing to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. P.Y.I.

8544(A)

POSITIONS WANTED

GEOLOGIST, Ph.D., Jan 1979. Spec. sedimentology, inorg. geochem. Long exp. teaching, uranium prosp., X-ray diffract., X-ray fluores. A.A.S., D.T.A., fluorimetry. Shipboard and overseas exp. Participation in inter. sci. proj. Organisation talent. Publ. Perfect English and German. 39 years, single. Europe, Australia. Box No. 8564. Nature, 3 Dyers Buildings, Holborn, London EC1N 2NR.

8564(B)

AGRONOMIST (B.A., M.A.) (Cantab). SPECIALIST RESEARCH/ADVISORY AGRONOMIST IN TEA seeks appointmen with any Research or Advisory Organisation, or Tea Company on Consultancy or Short Term Contract Basis. In my 50's and offer over 22 years' Research and Advisory experience in Ceylon, East and West Africa, Madagascar and Morocco. BILINGUAL. Fluent French. Also 2½ years SUGAR CANE Research, NATAL. Please reply to Nature, Box No. 8553(A) 3 Dyers Buildings, London EC1N 2NR.

SYMPOSIA

CHEMISTRY OF THE PYRETHROIDS
ST CATHERINE'S COLLEGE, OXFORD, JULY 16–19, 1979

The Fine Chemicals and Medicinals Group of the Chemical Society and **the Pesticide Group of the Society** of Chemical Industry are arranging a **symposium on 'Recent Developments** in the Chemistry of Pyrethroids' at **St Catherine's College, Oxford from** July 16–19, 1979.

The symposium will cover aspects of the chemistry of both natural and **synthetic compounds, eg novel** synthesis and synthetic methodology, novel **structures, process chemistry, photochemistry,** biosynthesis, and stereochemistry. **The organising committee has therefore** approached leading academic and **industrial workers for invited papers** to achieve a balanced and attractive **programme.**

Principal participants include—

Professor J. E. Casida, University of California
Professor L. Crombie, University of Nottingham
Dr M. Elliott, Rothamsted Experimental Station
Professor K. Kondo, Sagami Research Centre
Dr J. Martel, Roussel Uclaf
Professor R. A. Raphael, University of Cambridge
Professor I. Yamamoto, Tokyo University of Agriculture

and invited papers will also be contributed by—

Bayer; Ciba-Geigy; FMC; ICI; Roussel Uclaf; Shell;
Sumitomo; Zoecon.

Intending participants who wish to receive the final programme and details of **accommodation and registration** costs should write to:

Dr P. Doyle
ICI Plant Protection Division
Jealott's Hill Research Station
Bracknell, Berkshire RG12 6EY
England

Anyone wishing to contribute a short paper should submit by December 31, 1978, a title, names of authors (speaker underlined) and a summary of 200–250 words to assist the organising committee to select papers consistent with the aims and scope of the symposium.

8538(M)

STUDENTSHIPS

UNIVERSITY OF KENT AT CANTERBURY
BIOLOGICAL LABORATORY
RESEARCH STUDENTSHIP

Applications are invited for a C.A.S.E. studentship, funded by the Science Research Council and May & Baker Ltd., and leading to a Ph.D. degree. The research topic is concerned with the role of the microtubular system in liver metabolism. **The starting date will be January 1. 1979 as as soon as possible thereafter.**

Application forms and further particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH. The closing date for applications is December 8, 1978. Please quote ref: PG15/78.

8562(F)

FELLOWSHIPS

POSTDOCTORAL FELLOWSHIP

Available from January 1, 1979 for a Ph.D. graduate in biochemistry, virology or related area interested in studying the structure and replication of mammalian picornaviruses. Applicants must have received the Ph.D. degree no earlier than April 1, 1978. Salary is $11,600 for the first year.

Send curriculum vitae and references to Dr D. G. Scraba, Department of Biochemistry, University of Alberta, Edmonton, Alberta T6G 2H7 Canada.

8388(E)

FELLOWSHIPS CONT'D

EMBO
European
Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1979 AWARDS

Next deadline: February 20, 1979

The long term fellowships will usually be for a period of up to one year but applications for a renewal for a second year are considered. To be eligible a candidate must hold a doctors degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel. EMBO long term fellowships are **not,** however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

The deadline for applications for the 60 fellowships to be awarded in April '79 is February 20, 1979. Because the selection procedure involves an interview this deadline should be respected.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R. Germany. 8520(E)

LA TROBE UNIVERSITY
Melbourne, Australia
SCHOOL OF PHYSICAL SCIENCES
DIVISION OF THEORETICAL AND SPACE PHYSICS

RESEARCH FELLOWSHIP

A Research Fellowship is available in the Division of Theoretical and Space Physics for work on theoretical problems in wave-particle interactions in the earth's magnetosphere. The Research Fellow will work with Professor K. D. Cole from whom further details can be obtained.

The successful candidate may be appointed for a period of up to two years and would be expected to take up his position as early as possible in 1979.

Salary: $A15,860 per annum. Some travel support to take up the appointment is available.

Further information and application forms available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close with the Staff Officer by **January 31, 1979.**

8510(E)

QUEEN MARY COLLEGE
University of London
CHEMISTRY DEPARTMENT
Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP

for work with Professor R. Bonnett (in collaboration with St Mary's Hospital Medical School) on the development of tetrapyrrole photosensitisers. The project would suit an organic chemist with experience in heterocyclic synthesis, but an interest in biochemistry and photochemistry would be an advantage. Starting date January 1, 1979 or as soon as possible thereafter. Salary in range £4,359 to £4,858 p.a. (under review, including London Allowance). Please apply by letter giving age, qualifications, experience and names of 2 referees to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS.

8509(E)

COURSES

A COURSE ON CLINICAL IMMUNOLOGY

is to be held in Edinburgh, April 2–6, 1979
in Room 8, William Robertson Building, George Square

The object of this 5-day course is to provide a synopsis of modern basic immunology as applied to clinical medicine. The course is comprised of the following topics and speakers:

Introduction to immunology	1.	Dr W. J. Irvine, Royal Infirmary, Edinburgh.
The macrophage and immunity	2.	Dr D. M. Weir, University of Edinburgh, Edinburgh.
Allergy	3.	Dr W. E. Parish, Unilever Research, Bedford.
Renal diseases	4 & 5.	Professor D. K. Peters, Royal Postgraduate Medical School, Hammersmith Hospital, London.
HLA-system and disease	6.	Dr J. R. Batchelor, Queen Victoria Hospital, East Grinstead.
The immunology of viral infections	7.	Dr Pamela Ewan, Royal Postgraduate Medical School, Hammersmith Hospital, London.
Clinical Case—the immunology of non-viral infections	8.	Dr C. M. Feek, Royal Infirmary, Edinburgh.
Endocrine diseases	9 & 10.	Dr W. J. Irvine, Royal Infirmary, Edinburgh.
Immunodeficiency diseases	11.	Dr A. D. B. Webster, Northwick Park Hospital, Harrow.
Haematology	12.	Dr A. C. Parker, Royal Infirmary, Edinburgh.
Chest diseases	13.	Professor J. Pepys, Cardiothoracic Institute, London.
Liver diseases	14.	Dr R. Williams, King's College Hospital Medical School, London.
Dermatology	15.	Dr R. St C. Barnetson, Royal Infirmary, Edinburgh.
Neurology	16.	Dr H. Valdimarsson, St Mary's Hospital Medical School, London.
Gastroenterology	17 & 18.	Dr M. B. Pepys, Royal Postgraduate Medical School, Hammersmith Hospital, London.
Rheumatology	19 & 20.	Dr G. R. V. Hughes, Royal Postgraduate Medical School, Hammersmith Hospital, London.
Transplantation	21.	Mr J. E. Castro, Royal Postgraduate Medical School, Hammersmith Hospital, London.
Immunology of Cancer	22.	Mr J. E. Castro, Royal Postgraduate Medical School, Hammersmith Hospital, London.
Immunosuppression	23.	Dr J. G. McVie, University of Glasgow, Glasgow.
Myasthenia Gravis	24.	Dr W. J. Irvine, Royal Infirmary, Edinburgh.

The registration fee up to January 31, 1979 is £65 (excluding accommodation and meals) and £80 thereafter. Accommodation will be available at the University Halls of Residence, but if alternative accommodation is required it should be booked direct Regstration form, further particulars and enquiries should be addressed to:

Dr W. J. Irvine, Endocrine Unit and Immunology Laboratories, Royal Infirmary, Edinburgh EH3 9YW (UK).

8575(D)

London School of Hygiene and Tropical Medicine and The Royal Postgraduate Medical School (University of London)

MSc in Medical Microbiology

Advanced academic and practical training in bacteriology, virology, immunology, mycology, microbial genetics and medical parasitology as applied to clinical and preventive medicine is provided through an intercollegiate course of study extending over two years.

The first year will be spent at the two Schools of the University followed by a second year at a recognised laboratory. Candidates with satisfactory evidence of prior supervised practical training may be exempted from the second year of study.

The course is open to medical, dental and veterinary practitioners, graduates in science or pharmacy and other suitably qualified students.

Exemption from the Primary Examination for the MRC Path may be granted to successful candidates. The course is accepted as recognised training for College examinations.

A limited number of Medical Research Council awards may be available to suitably qualified British subjects resident in the United Kingdom.

Closing date for applications: 1 March, 1979.

Further particulars from the Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT.

8513(D)

ASSISTANTSHIPS

ENVIRONMENTAL SCIENCE/CHEMISTRY

Teaching, Research Assistantships for graduate study in M.Sc. and Ph.D. program. Specialisations include aquatic and atmospheric chemistry. Write to Dr Raymond Lutz, Dept. of Chemistry, Portland State University, P.O. Box 751, Portland, OR 97207 USA. Equal Opportunity Employer.

8580(P)

GRANTS

UNIVERSITY OF LONDON GRANTS FOR RESEARCH

Applications are invited from members of the University and teachers in Schools of the University for grants from the Central Research Fund to assist specific projects of research and for the provision of special materials and apparatus. Grants are not made for normal maintenance. Applications must next be received not later than December 15, 1978. Forms of application and further particulars may be obtained from the Secretary to the Central Research Fund, University of London, Senate House, London WC1E 7HU.

8536(H)

UNIVERSITY OF BRISTOL

12 MONTHS M.Sc. COURSE BY ADVANCED STUDY AND RESEARCH

are offered in the following subjects:

Advanced Analytical Chemistr
(Inorganic Chemistry)
Surface Chemistry and Colloid
(Physical Chemistry)
The Physics of Materials (Physics
Mathematical Logic and Foundations of Mathematics (Mathematics)
Fluid Mechanics (Mathematics).

All five courses qualify for a quot of S.R.C. advanced course studen ships. Further details of the individu courses may be obtained from th Head of the Department concerne University of Bristol, BS8 1TH. Enquiries are also invited for details o opportunities for research leading t the degree of Ph.D. 8568(D)

4TH FLOW LABORATORIE SPECIAL TECHNIQUES COURSE
on
DIAGNOSTIC METHODS IN CLINICAL VIROLOGY
April 2–6, 1979
University of Surrey
Guildford, UK

The Course will be run by Dr A. Smith and J. Bertrand, and wi consist of lectures, demonstrations an practical exercises involving Ce Culture, Preparation of Clinical Spec mens, Complement Fixation, Haemag glutination, Immunofluorescence Radial Haemolysis, Virus Neutralisa tion, Electron Microscopy, Radioin munoassay and Enzyme Immunoassa

The fee for the Course will be £13 inclusive of meals and accommodatio

Application forms may be obtaine from Dr S. A. S. Volkers, Flo Laboratories Limited, Irvine, Aryshi KA12 8NB, Scotland. 8532(D)

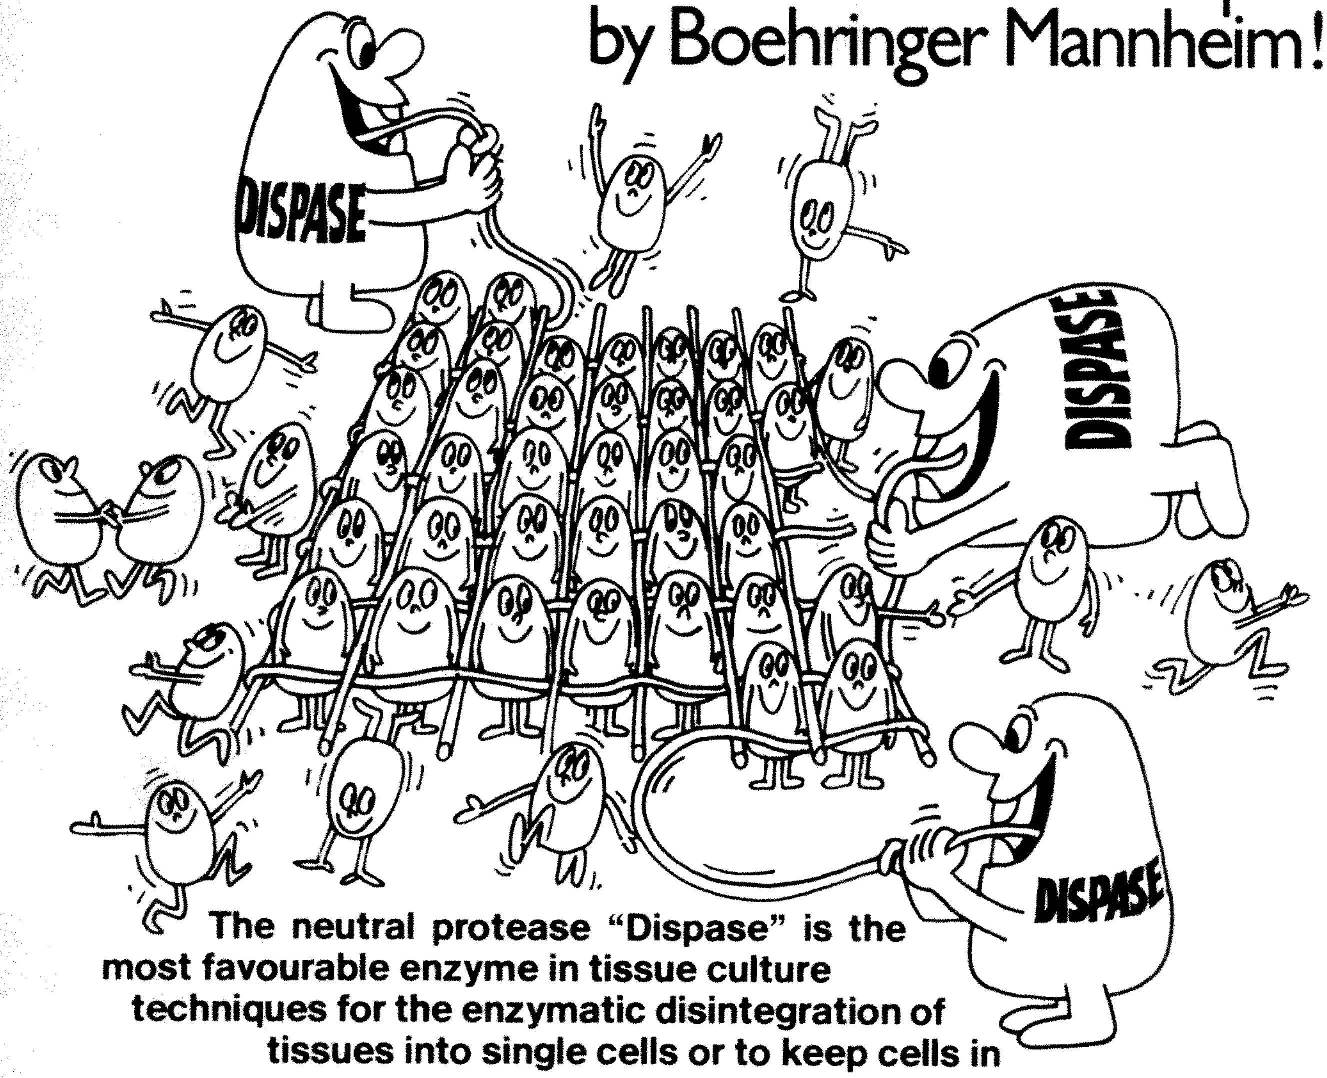
The big liberator is here!

A revolution in tissue culture techniques by Boehringer Mannheim!



The neutral protease "Dispase" is the most favourable enzyme in tissue culture techniques for the enzymatic disintegration of tissues into single cells or to keep cells in suspension culture.

The advantages over trypsin are:

- ✱ no damage of cell membranes
- ✱ no inhibition of cell growth
- ✱ tissue disintegration in presence of a complete nutrient medium even with serum
- ✱ increase of the yield of living cells
- ✱ no loss in enzyme activity under tissue culture conditions
- ✱ no contamination by viruses or mycoplasms possible

Commercially available:
Dispase, Grade I, Cat. No. 241 750
Dispase, Grade II, Cat. No. 165 859
Dispase/Collagenase mixture, Cat. No. 269 638

The third edition of the BDH laboratory wall chart 'Properties of gases' has just been printed.

It measures 620 mm by 890 mm.

It lists over 100 gases.

It gives, where appropriate, the British Standard cylinder colour code, the hazard warning symbols recommended by the Council of Europe, the threshold limit value, the vapour pressure, the specific gravity, the boiling point, the freezing point, the critical temperature, the critical pressure, the formula and the molecular weight of each gas.

It costs £3·25.

Ask for a copy of our leaflet 'Books & Charts' which gives details of all BDH saleable publications.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

Communal breeding in green woodhoopoes as a case for reciprocity — *J. D. Ligon and S. H. Ligon* — 496

When you're studying cyclic nucleotides and you don't know which way to turn

We understand that when you are working in the cyclic nucleotide area, the subject is so diverse and so complex that you don't want to have to worry about the problems of accurate measurement.

So we would like to take a little weight off your mind and offer you our two kits in this field.

Cyclic AMP and Cyclic GMP.

Both of the tests are simple, accurate and will take you about four hours from start to finish.

So it's not surprising that you can carry on with your research and leave the problems of accurate measurement to us.

You know where you are with our Cyclic AMP & GMP kits

Rothschild's numerate arrogance

Lord Rothschild, speaking on British television last week, argued that we should develop a table of risks so we could compare, say, the risk of our dying in an automobile accident with the risk of Baader-Meinhoff guerillas taking over the nuclear reactor next door. Then we would know how seriously to take our risks, be they nuclear power, damage to the environment or whatever. The 'econuts' (Lord Rothschild's usage) would soon be put in their place if we put numbers to the risks they envisage. What could be more reasonable than that? Has Rothschild lightened the darkness of the risk business with the light of science and number?

No. It is fine for Rothschild to demonstrate his agility with arithmetic, converting probabilities from one form to another (and implying that the viewers could not do it) but this is only the kindergarten of risk. He gave only the briefest of hints that there might be more to it when he called for errors to be quoted with risk estimates and when he remarked—in a brief aside—that occasionally one had to rely on expert assessment of risks, as in the case of nuclear reactors. But he threw these cautions away when he quoted not a single error on the risks he enumerated, nor developed the problem of the partisan 'expert'.

More than this, Rothschild confused two fundamental distinct kinds of risk in his table: known risks—such as car accidents—where the risk is simply calculated from past events; and unknown risks—such as the terrorists taking over a fast breeder—which are matters of estimating the future. The latter risks inevitably depend on theory. Whether the theory is a social theory of terrorism or a risk-tree analysis of fast breeder failure, it will be open to conjecture. And it ought to be remembered that the history of engineering is largely a history of unforeseen accidents. Risk estimates can be proved only by events. Thus it is easy for groups, consciously or unconsciously, to bend their calculations to suit their own objectives or prejudices. With unknown risks it is as important to take these into account as to come up with a number. Hence the danger of relying on 'experts' who are committed to a particular future. What is needed more than an expert table of risk values is a democracy of risk assessment, where the basic information on which conjectural risks are calculated is made available to as many groups as possible.

Moreover some future risks are largely incalculable because we have no theory. What is the risk, for example, of a fast breeder economy leading to an erosion of civil liberties? This is a matter of legitimate concern, but how can Lord Rothschild's table deal with it? It is a conceit among some scientists that scientists alone are rational, and Lord Rothschild projected this conceit particularly clearly.

Peter Chapman, Director of the Open University Energy Group, caricatured this view when he spoke to the Parliamentary Liaison Group for Alternative Energy Strategies last week: "'rational' things, facts, are concerned with the reproducible aspects of the world. In the energy business this means the efficiency of machines, the heat loss from houses, the number of houses and so on. If we agree on the meaning of these terms we can agree how to measure them and hence have a basis for agreeing what to do. Anything that cannot be measured (and this included all my emotional reactions to things, people, and relationships) has to be left out. It is dubbed 'irrational' and excluded."

Science and numeracy are undoubtedly important parts of rationality, but they are by no means the whole of it; and scientists do a disservice to both by pretending that they are. In part they fail to distinguish the process of science from the product. Science in the making—like a projected risk—is always conjectural and hypothetical; it is confirmed by repeatability (part of the philosophy of a democracy of risk) and acceptance within the scientific community (a social event). It is never a matter of 'experts'; that is mere scholasticism. Future risks must be science in process for there can—by definition—be no experiment.

It is objective and rational to take account of imponderable factors. It is subjective, irrational, and dangerous not to take account of them. As that champion of rationality, the philosopher Bertrand Russell, would have argued, rationality involves the whole and balanced use of human faculty, not a rejection of that fraction of it that cannot be made numerical. By all means let us have numbers, where they can be agreed upon; but let us not be mesmerised by them. □

US to increase public participation in regulation of DNA research

SIGNIFICANT changes in procedures for regulating research involving recombinant DNA techniques are soon to be announced by the US National Institutes of Health (NIH). In particular, there will be greater public participation in both local biosafety committees and the NIH's Recombinant DNA Advisory Committee; and tighter provisions determining responsibility for ensuring that regulatory guidelines are observed.

Other changes expected to be announced are expansion of the scope of the present guidelines to cover recombinant DNA research carried out in institutions receiving support for such research from any federal agency (not just NIH); stricter rules about the public notice required to alter the guidelines; and increased provision for taking "risk assessment" considerations into account when deciding whether certain types of experiment should be exempt from the guidelines.

A revised version of the guidelines, which were first introduced by NIH in July 1976, were delivered to Secretary for Health, Mr Joseph Califano, at the end of last week. If he approves the changes, as is expected, then the new guidelines will be published in the *Federal Register* within a few weeks.

Proposed revisions to the guidelines were issued by Dr Donald Fredrickson, director of NIH, earlier this year. In particular, Dr Fredrickson has recommended lowering the levels of containment required for certain types of experiments (and to exempt other experiments from the guidelines completely) in the light of scientific evidence that has accumulated since concern over the possible social impact of recombinant DNA research was first raised five years ago.

Most of the suggested revisions to the scientific aspects of the guidelines are expected to be retained in the final version, apart from a few deletions from the list of exemptions. The major changes will occur in Part IV of the guidelines, that which covers "roles and responsibilities".

Much of the impetus for this change has come directly from Mr Califano, responding on the one hand to pressures from Congress—which is still threatening to introduce legislation to make up for any deficiencies it perceives in the guidelines—and on the other to public interest and environmental groups, which have been consistently critical of what they see as attempts to retain decision-making within the scientific community.

When NIH's proposed revisions were published, Mr Califano added an introduction specifically requesting comments on the proposed mechanisms for administering and revising the guidelines. Many such comments were aired at a public meeting held in Washington in September before a departmental review committee established by Mr Califano under the chairmanship of Mr Peter Libassi, chief counsel of the Department of Health, Education and Welfare.

According to sources in Washington, the major impact of the review committee's intervention and its study of the various comments and criticisms received, will involve aspects of public participation in the regulatory process, as well as channels of responsibility and accountability.

In his proposed revisions to the guidelines, for example, Dr Fredrickson had suggested that considerable authority for the conduct of recombinant DNA experiments be devolved from NIH to local biosafety committees; and that, in addition to including those with expertise in the relevant fields of science and public policy, at least one member of such a committee "shall not be affiliated to the institution."

Critics, such as Friends of the Earth and the Environmental Defense Fund, argued that this did not go far enough in involving the public in the regulatory process, in particular since the wording still allowed the external appointment to be made by the institution. The final version is expected to say that at least two members—or 20% of the total—should be appointed from outside, for example from environmental groups or local or state safety bodies.

Furthermore, membership of the Recombinant DNA Advisory Committee, another target of criticism, is to be increased from 14 to 20; the number of "public interest" representatives, is expected to be increased from two to six.

Additional changes to NIH's suggestions in the final version of the guidelines include clearly stated procedures for the director of NIH to adopt if it is proposed to make changes in the guidelines, specifying which changes need to be offered for public comment, which require advance notice, and which can merely be announced. Provision is also expected to be included for NIH to be able to remove the authority delegated to a local biosafety committee if it considers the committee's performance to be unsatisfactory.

One target of criticism in the suggested revisions was the proposal that, although certain types of experiments would continue to be prohibited, case-by-case exceptions would be allowed for experiments for which there were "compelling social or scientific reasons", provided that weight was given to "scientific and social benefits and to potential risks".

This language is now to be tightened up, so that the general standard for all such decisions will be an assessment that the experiment in question poses "no serious risk".

Two final points relate to the commercial aspects of recombinant DNA research. Firstly, the advisory committee is to be asked to consider what ground rules should apply to experiments involving more than 10 litres of culture containing altered genes.

All such experiments—not merely those involving "harmful products," as at present—would be prohibited, but still subject to waiver by the director of NIH; in commenting on this ban, the pharmaceutical company Eli Lilley told Dr Fredrickson that the necessity for such experiments was "imminent".

Secondly, reflecting a concern that a "voluntary" approach to regulating experiments in private industry suggested by NIH is likely to prove inadequate, the Food and Drug Administration is to consider whether similar guidelines should be applied directly to the pharmaceutical industry.

Many of the expected changes are likely to be welcomed by public interest and environmental groups, since they go some way towards meeting the criticisms of the guidelines on which such groups have been concentrating in recent months. "Any movement towards more responsible mechanisms for operating the guidelines is a step in the right direction," Dr Jonathan King, professor of biology at Massachusetts Institutes of Technology said last week.

Officials at NIH are said to be less happy, fearing that they are being pushed into a more regulatory role than many would wish, and are losing some of their flexibility to manoeuvre. Publication of the revised guidelines is thought to have been delayed by negotiations between NIH and DHEW.

Many of the changes answer criticisms given by Senator Adlai Stevenson, in a letter to Mr Califano last month, as reasons why he considered legislation still necessary. Mr Stevenson is said to be happier with the final version and the prospect of legislation may be receding.

US and Japan to cooperate in fusion and high energy physics

A BROAD programme for collaborative research in a number of areas of energy science has been agreed in principle by the United States and Japan. The programme, which will include fusion research and high energy physics, is expected to involve expenditure of about $1,000 million by the two countries over the next ten years.

The main areas of collaboration were agreed during a visit to Japan in September by Dr James Schlesinger, Energy Secretary, and Dr John Deutch, head of the Department of Energy's office of energy research. The details were worked out in a series of meetings held in Washington last week; and it is hoped that an agreement will be signed within four months.

The two main items in the programme are research into magnetic fusion, and into liquefaction of coal. In addition, the two sides have agreed to cooperate in solar photovoltaics, geothermal energy, and high energy physics.

As far as fusion is concerned, the main focus of Japanese interest will be the General Atomic Company's large Doublet III programme in San Diego, to which the Japanese are expected to contribute about $50 million.

In addition, the two sides have agreed to set up a joint research institute for fusion research. The Japanese end of the institute will probably be in Nagoya; no decision has been reached on a US site, with Massachusetts Institute of Technology and the University of California at Los Angeles being possible contenders.

In return for being allowed to participate in the fusion programme, the Japanese have agreed to contribute 25% of the costs of a $700 million coal conversion demonstration plant planned for construction by Gulf Oil in West Virginia. The German government has already agreed to contribute a further 25%.

As for high energy physics, the two sides have in principle agreed on joint research and development into accelerator and particle detection technology and the joint construction and use of new facilities. It has been suggested for example that the Japanese may contribute to enhancing the 400 × 400 GeV intersecting storage accelerator (ISABELLE) at the Brookhaven Laboratory on Long Island. In the longer term, many US physicists are hoping that it may be possible to obtain joint funding for the next generation of particle accelerators. **David Dickson**

Home insulation may increase radiation hazard

SCIENTISTS at the University of California's Lawrence Berkeley Laboratories have suggested that the reduced ventilation in private houses resulting from conservation measures may pose a potential health hazard, by increasing exposure to low levels of the radioactive gas radon.

Radon-222 is produced as part of the decay chain of uranium-238. Both the gas and its short-lived decay "daughters"—in particular the alpha-emitters polonium 218 and 214—are present in the natural environment and are a recognised source of background radiation. Furthermore, radon's precursor, radium-226, is a trace element contained in most rocks and soil; and indoor radon sources therefore include many building materials.

The health hazard is caused principally by radon's daughters, which can attach themselves to airborne particles and if inhaled, can lodge in the lung and emit short-range alpha radiation. In recent years, the hazardous aspects of high-level radon exposure have been dramaticaly highlighted by the high incidence of lung cancer among uranium miners. And only recently the federal government has been taking steps to minimise public exposure to the radon emitted by uranium mill tailings.

Six scientists at the Lawrence Berkeley Laboratory's energy and environment division have now suggested that, if medical data from the uranium miners is extrapolated backwards—and assuming a no-threshold, linear dose-response relationship at low levels of exposure—the decreased ventilation in private homes achieved in the interests of energy conservation could theoretically lead to an extra 20 to 200 annual deaths per million population from lung cancer.

The scientists point out that despite recent interest in the effects of radon exposure in both Sweden and the UK, there is still little detailed knowledge about the effects of low level exposures over long periods of time, and that any conclusions are highly speculative. "We are not issuing a warning, but merely calling attention to a possibility that should be watched and studied", says Dr Craig Hollowell, one of the scientists concerned.

Despite this, a report produced by the scientists states that: "It is likely that some increased lung cancer risk would result from increased radon exposures; hence it is desirable not to allow radon concentrations to rise significantly".

In the long term, the scientists suggest that it may be necessary to include radon exposure levels in building standards. In the short term, they suggest a number of measures—such as sealing walls and floors, or coupling mechanical ventilation with heat exchangers—to reduce radon exposure.

The scientists have applied to the Department of Energy for further funds to carry out a more detailed investigation of the potential hazards—a request which has fallen between the department's environmental health and conservation responsibilities.

Some money has already been granted to study the radon emission of building materials. A complementary proposal for studying the health effects is being considered by the department's office of energy research. No one is yet prepared to admit that increased radon exposure does pose a health hazard, however small; but with growing concern about the long-term effects of low level radiation, no one is yet prepared to dismiss the hypothesis as unfounded. **David Dickson**

New Spanish Constitution leaves science policy open

THE Spanish Parliament has just voted by a large majority (more than 90%) for the second democratic Constitution of this century. On 6 December the Spanish people are called to vote the text in a referendum. The main political forces, from extreme left to neofrancoists, will campaign for its approval.

Science is mentioned twice in the first part of the new Constitution. Article 20 recognises "the right to literary, artistic, scientific and technical production and creation" and article 44 says that "the public powers will promote science and technical and scientific research for the benefit of general interest".

The mention of research in the articles dealing with the organisation of the State may be of greatest significance for scientists. One of the central constitutional problems has been the formation of autonomous governments in different parts of Spain. Article 148 lists the matters transferable to autonomous communities and it includes "the promotion of culture and research". However "the promotion and general coordination of technical and scientific research" can be found in the list of matters reserved

0028-0836/78/0276—0431$01 00

for central government. Nevertheless anything is possible because article 150 says that the central government may transfer or delegate to autonomous communities matters attributed to it.

The reason why the organisation of research is mentioned in the Constitution comes from the present unequal distribution of research centres in Spain. The question is left open because some people think that if control over research is given to autonomous governments research would be more balanced and related to the needs of different areas; others fear that it could be more difficult for a smaller community to build an appropriate system of financing research and that coordination may not be easy.

Parliament will have to make a decision on these issues within the next few months. From a practical point of view it is very important that decisions are made quickly as the present provisional situation in science makes work very difficult. For instance one of the main sources of research funds (FNDICT) may disappear next year and laboratories have not yet received the credits corresponding to applications made in 1977.

What remains to be seen is if political decisions will be taken soon enough to prevent the closing of certain laboratories and if the problems are treated with sufficient imagination to achieve an adequate structure for research.

Pedro Puigdoménech

Sweden's new government wrestles with nuclear power

NUCLEAR power has finally proved to be the undoing of Sweden's first non-socialist coalition government in 44 years. Former Prime Minister Torbjörn Fälldin handed his resignation to the Speaker on 5 October.

The government fell because some members of Fälldin's Centre Party opposed the coalition's decision on the loading of two reactors: Ringhals 3 and Forsmark 1. Under the Stipulation Law, the reactor owners could be given permission to load only after they had secured an acceptable reprocessing contract. They also had to show how and where the highly-radioactive waste resulting from reprocessing could be finally stored. Judging the application by these criteria, the government found "that the preconditions for consent are deficient in one respect. The application cannot therefore be approved".

The government went on to say that in order for the application to meet the conditions laid down for secure final storage, there should be test drilling to "show the existence of a sufficiently large rock formation of appropriate depth" with the qualities already prescribed by the nuclear industry's Nuclear Fuel Safety (KBS) project*. If the applicants found rock they considered suitable and applied again, the government would ask the Nuclear Power Inspectorate to judge the application. If the Inspectorate approved it, the government would give permission for the reactors to be loaded.

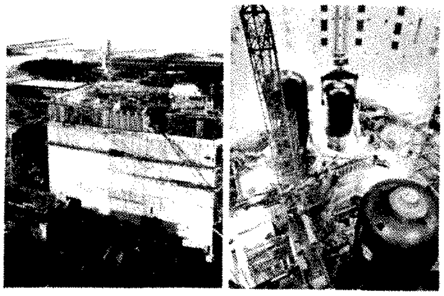
This agreement was immediately interpreted by the Press as a 'soft yes' to the loading, as it was assumed that the test drilling was a mere formality which would quickly produce the required rock. The Centre Party was criticised for yet another capitulation: although anti-nuclear, it had made several compromises on the issue during the government's term. How much influence these attacks had is uncertain, but, at the insistence of former Energy Minister Olof Johansson and other members of the Centre Party, Fälldin demanded that his coalition partners should agree to a referendum on the issue. They refused, and the government fell.

After much speculation, a minority Liberal party government was sworn in on 18 October. The new Energy Minister, Carl Tham, favours nuclear energy, but his statements since becoming Minister have been cautious.

Tham has said that the investments already made in nuclear reactors should not be wasted, and that those already in operation or being constructed should be used if security demands can be met. This would mean drawing the nuclear line at eleven reactors. He also wants to tighten up security on all energy forms. The new government will, he says, follow the old one's agreement on the Ringhals 3 and Forsmark 1 reactors.

Since the government's fall, debate has raged over the extra drilling requirements. Will they prove to be a simple formality, or was this a subtle way of delaying the two reactors perhaps for years? Engineer Lars Bertil Nilsson, chief of the KBS project, is confident that suitable rock will be found quickly. "There are certainly many places in Sweden where the rock is suitable", he says. "According to the government's statement, we simply have to find one of them. We don't need to choose any particular place now for final storage: that's a long-term business and will need to take a lot of other things into account besides the rock itself: buildings, transport, public opinion, etc. All we have to do now is to show that suitable rock exists. It is our judgement that we need only drill four new holes at Finnsjön, near Forsmark, and three new ones at Karlshamn. The drilling has just begun and will be finished by the end of the year. Then we'll put our report together and make a new application to the government in 1979."

His optimism is not shared by various researchers and some of the geologists actually doing the drilling. They have claimed that reliable results cannot be expected before two to ten years.



Forsmark 1 and Ringhals 3 under construction.

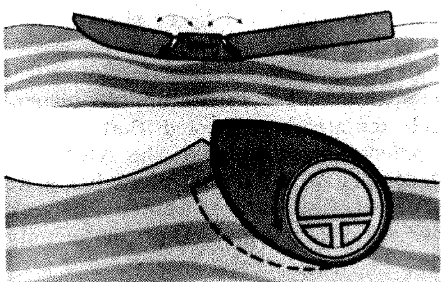
Meanwhile, the Nuclear Power Inspectorate is preparing itself for the new application. According to Dr Thomas Johansson, Vice-Chairman of the Inspectorate's Board, an expert panel of geologists is being set up to review the application. Before it is presented, however, the board is asking the panel to discuss guidelines for its evaluation. The panel should list the qualities that the nuclear power industry has said suitable rock should have; discuss possible measuring techniques that could be used to claim that the rock actually has the required characteristics; and decide what constitutes "showing" that the rock is suitable. "None of the geologists on the panel is involved in the drilling", says Dr Johansson. "The intention is to have a completely independent review."

What, then, of the future? "I am rather pessimistic", says anti-nuclear activist Björn Gillberg. "The Centre Party committed suicide when it passed the Stipulation Law. Whether or not we want nuclear energy should be decided on very broad grounds: social, political, psychological, environmental, international. To reduce it to the technical handling of waste, as the Law does, simply turned out to be a trap. The Centre Party didn't realise it had set a trap for itself until it was too late. They're nice guys, but they're naive. I can see the [pro-nuclear] Social Democrats winning next year's elections."

Wendy Barnaby

**The first KBS report, against which the Ringhals 3 application was judged, is called "Handling of Spent Nuclear Fuel and Final Storage of Vitrified High Level Reprocessing Waste". It is available from KBS, Brahegatan, S–102 40 Stockholm.*

Enthusiasm for UK wave power survives high costs



The Cockerell raft (top) and Salter duck

WAVE energy is not the white knight rescuing the fair society. That seems certain. Nevertheless the participants at a conference on the UK wave energy programme in London last week were optimistic about their ability to solve eventually the formidable problems of harnessing the power of the waves through steady work. And they were equally optimistic about the value of doing so.

The bad news about wave energy is that estimated costs per kW installed for the UK are £5,000-£9,000 compared to £500-£1,000 for a fossil or nuclear station. Current devices are a factor of 20 too costly for the value of the energy they can produce, concludes a report prepared by the consulting firm of Rendell, Palmer and Tritton in conjunction with Kennedy and Donkin. Referred to as a 'hatchet job' by observers outside the wave energy programme, the RPT report, commissioned by the Wave Energy Steering Committee, does not appear to have lowered morale. As Dr Stephen Salter of Edinburgh University, designer of one of the principal devices, the Salter duck put it: "Sir Hermann Bondi (Chief Scientist in the Department of Energy) has given us the best wings money can buy. RPT has told us how hard the ground is and the rest is up to us." Clive Crove Palmer, Programme Director of Harwell's Wave Energy Group told the conference: "This group thrives on problems and challenge. They won't just lick them, they'll eat them."

The high cost of the early designs arises from the diffuse character of the waves themselves. To capture the energy, large areas of device have to face the on-coming waves. With either concrete or steel the designs have been expensive. "But remember", says Grove-Palmer, "the Wright brothers' first estimate of the cost of air travel was $30,000 per mile and they went right ahead".

The UK is favoured with some of the best off-shore sites in the world for the exploitation of wave power. Energy in waves is governed by wind strength and length of water over which the wind blows. Prevailing Westerly winds blowing across as much as 1,000 miles of the North Atalantic create waves of average power of 50 kW per metre of wave front.

Since the UK wave power programme is only two years old and since the conference participants have an obvious enthusiasm for what has been accomplished with the first generation devices, Grove-Palmer's optimism may be justified. What, then, has been achieved in two years?

Two of the main devices are the Cockerell raft and the Salter duck. The Cockerell raft uses the relative angular motion of two segments of raft and the Salter duck uses a similar action of oscillating pods about a common spine. The precise mode of conversion is a subject of study. The rocking action can be used to drive a pump which can pressurise a fluid which can drive a turbine. But other proposals include on site conversion to hydrogen, on site desalination or direct use of the mechanical power to make heat.

Other devices under active consideration are the oscillating water column (OWC) and the Lancaster University flexible bag. The OWC is a box with a hole in the top. The waves make the water level oscillate and air is forced through the hole to drive a turbine. The flexible bag is potentially the cheapest design. Air filled bags are attached to a submerged hull. The wave crests collapse the bags and the displaced air drives a turbine. The bags are filled during wave troughs from a low pressure duct.

Grove-Palmer detailed six areas of future work in his closing summary.

- The need for better wave data. The irregularity of the waves in height and direction needs study. According to M. J. Platts of Wavepower Ltd, the builders of the Cockerell raft, one difficulty is that the oil industry has kept its accumulated wave data from the North Sea platforms 'inaccessible'. Platts has been unable even to arrange a visit to one of the platforms.
- Detailed critical engineering studies of how best to extract the power.
- Spine articulation of Salter's ducks. The bending moments are severe.
- Tests of the oscillating water column in real sea conditions.
- Further tests of the flexible bag because of its low cost.
- Mooring. Existing mooring equipment has been designed for ships and is unsuitable. Equipment is needed to withstand powerful mooring forces in high seas, corrosion and fouling by marine organisms over a period of 25 years without inspection. (Ships get drydocked every three or four years).
- Size and survival in high seas.

Aside from the technical problems are the problems of actually producing a large scale operational system. M. J. Platts estimates that all the design problems need to be solved and a fully operational production system needs to be built before 1990 if there is to be significant (20%) wave power production by 2020. After 25 years, production must be entirely given over to replacement so building up sufficient capacity before that time is a problem. Platts also points out that on this time scale one can expect significant social and economic changes which are impossible to predict.

A novel feature of the wave energy programme is the attention now being paid to environmental and social aspects. Preliminary estimates indicate that the effect of wave energy devices 10 km off shore will be to increase the size of beaches and the economic well being of the local population. But the lobster, herring and the £20,000,000 salmon industry are concerned that installation of the devices could interfere with the normal migration and mating behaviour of the fish. A third nuisance could be the possibility of seals finding the devices habitable with unknown consequences.

Problems of interfering with shipping are more serious. There are problems of collisions, the generation of rougher seas by wave reflections from the devices, and the need for reliable warning lights and radar reflectors to mark gaps up to 2 km wide to a standard much higher than ever attempted in the open sea.

To many wave energy is an attractive alternative energy possibility. "There is still a major amount of work ahead before conclusions can be reached about the future of the technology" said Dr F. J. P. Clarke, Chairman of the Wave Energy Steering Committee. But realism must tell us that any talk of a full scale or near full scale wave energy station out at sea by the early 1980s is premature. We still have to evolve concepts and engineering designs that would justify the major expenditure involved in such a step." Clarke tempers his judgement with a more positive note. "The resultant [wave energy] team . . . comprises a substantial national asset, and given continuous government support it is determined to find solutions. The natural resource is there and if anyone can learn how to capture it this team will."

Joe Schwartz

news in brief

Pochin calls for improvements in safety at Aldermaston: Substantial improvements in safety measures are urgently needed at the Atomic Weapons Research Establishment, Aldermaston, according to Sir Edward Pochin in his recent report on safety at AWRE. Workers there should be better protected from inhaling radioactive dust, the report says.

Pochin's inquiry, leading to the recent report, was set up following events last August when three women from the special laundry at AWRE were found to have plutonium in their lungs in excess of the level recommended by the International Commission on Radiological Protection.

In the report, Sir Edward says that the general level of health protection in the plutonium processing buildings is "of borderline adequacy", even though the industrial safety record is excellent.

Cutbacks in the number of safety staff and inadequate training had caused a serious decline in monitoring of radioactivity, he says, and, consequently, workers were being exposed to potentially dangerous levels of radioactivity. Monitoring standards had fallen behind those in other establishments in the UK and the US, although an increase in the number of personal air samplers, and a body counter to estimate plutonium in the lung, now being built, would improve matters.

Sir Edward recommends that in the long term major improvements should be made to buildings where solid and liquid waste are reprocessed; the containment of alpha-emitting radionuclides is very difficult with the present safety measures, he says.

AWRE and the National Radiological Protection Board have set up a joint committee to review the radiation exposures of individual workers, and inspectors from the Health and Safety Executive are to visit the establishment.

Supreme court rejects Podrabinek's appeal: Aleksandr Podrabinek (pictured right), the Moscow paramedic sentenced last August to five years internal exile last week had his appeal rejected by the Supreme Court of the Russian SFSR. The court stated that the charges of anti-Soviet slander had been upheld.

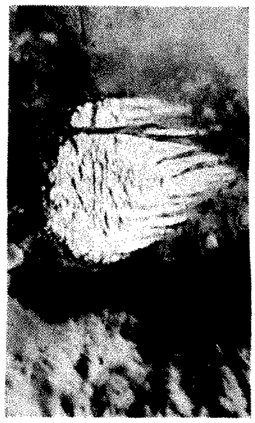
Mr Podrabinek, an active member of the illicit "Working Commission for the Investigation of the Use of Psychiatry for Political Purposes" is the author of a 265-page *samizdat* dossier on Soviet abuses of psychiatry to crush dissent.

Mr Podrabinek was not permitted to attend the appeal hearing. Nor was his chosen defence counsel, the London lawyer Louis Blom-Cooper. According to Mr Blom-Cooper Podrabinek's original trial involved the violation of no less than 78 provisions of Soviet legal procedure. Dissident sources in Moscow suggest the same pattern was followed at the appeal hearing—no defence witnesses were called nor was Podrabinek's own statement read to the presiding judges. *(Photo courtesy of Keston College.)*

Patent rights for university researchers: In an attempt to clear up the issue of whether patent rights for inventions made by researchers in British universities should be held by the researcher or the university, the Association of University Teachers (AUT) has sought the opinion of a leading firm of solicitors, which has said that the invention belongs to the researcher provided that he or she was not employed specifically to invent.

After the 1977 Patents Act, the Committee of Vice-Chancellors and Principals issued a report on the ownership of patents which tentatively suggested that the individual should hold patent rights. However, the AUT says that in the past most compensation for inventions has gone to the universities. The AUT, therefore, wanted "to seek an independent view", said Mr John Akker, its deputy general secretary.

The AUT hopes soon to begin talks with the Committee of Vice-Chancellors and Principals to lay down guidelines on the ownership of patent rights which could be applied to all British universities.



NASA is to investigate Martian "White Rock"; This strange, white, horseshoe crab-shaped feature found inside a Martian crater (see photo) is to be studied by scientists working with the NASA Viking mission. The feature, nicknamed 'white rock', is the only one of its kind on Mars. Its composition is unknown, but it is unlikely to be either ice or snow because it lies near the equator.

The 'white rock' is about 18 km long and 14 km wide, and is at the bottom of a crater located at 8° South, 335° West.

Women scientists still lag in US: Despite significant increases in the proportion of women science graduates emerging from US colleges and universities, their salaries are still lower than those of men with comparable training and experience at every age, every degree level, in every field and with every type of employer (except for chemistry BAs employed by industry), according to figures released last week by the US Scientific Manpower Commission.

The commission says that detailed statistical analysis of the participation of women in the professional labour force indicate that women have roughly doubled their proportion of earned degrees in the sciences since 1970, and quadrupled their share of engineering bachelor's degrees. However, unemployment rates for professionally trained women continue to be two to five times higher than for men in the same field with the same level of training, and the gap increases at higher levels.

In the federal government, women still lag well behind their male counterparts in grade level (and hence salary). Thus among the federal government's 1,700 microbiologists, the average salary is $23,260 for men and $18,550 for women.

New parliamentary group for alternative energy: The UK Parliamentary Liaison Group for Alternative Energy Strategies called its first public meeting last week at the House of Commons. Chaired by Frank Hooley, MP, and supported by many environmental groups, the Group called Sam Berman, Director of the Lawrence Berkeley Laboratories, Peter Chapman, Director of the Open University Energy Group, and Gerald Leach, of the International Institute for Environment and Development, to speak. The next meeting is on 29 January with Tony Benn, Secretary of State for Energy.

Health and safety research gets underway

The UK Health and Safety Executive (HSE) last week published its research report for 1977—the most comprehensive yet to be published on the executive's research activities. **Alastair Hay** here looks at the research labs run by the HSE.

FEW research institutes would complain about a yearly budget increase of more than 40%; fewer still would be able to approach this level. But last year the HSE spent £8.5m on 'research' testing, and scientific support activities", compared to £6m in the previous year. There is, however, good reason for the executive's windfall, as the 1977 research report makes clear. The HSE is a relatively new institution, brought into being by the 1974 Health and Safety at Work Act, and so is still growing.

The Act established a Health and Safety Commission (HSC), a body with the task of determining policy for health and safety in Britain. A tripartite organisation consisting of trade union, employer and local government nominees, the commission has a role which can be compared with that of a company board of directors, with the basic difference that of all its members, only the chairman is a full-time employee. The HSE was formed to implement the commission's decisions, and is responsible for the day-to-day policing the HSW Act.

All people at work—with the exception of domestic workers in private employment—are covered by the Act. The HSE required facilities from several of the more established ministries in order to carry out its obligations. The Alkali and Clean Air Inspectorate was transferred from the Department of the Environment, a move vigorously opposed by the DoE. Other transfers, from the Departments of Energy, Employment, and, Prices and Consumer Protection and the Ministry of Agriculture, Fisheries, and Food, were achieved more easily.

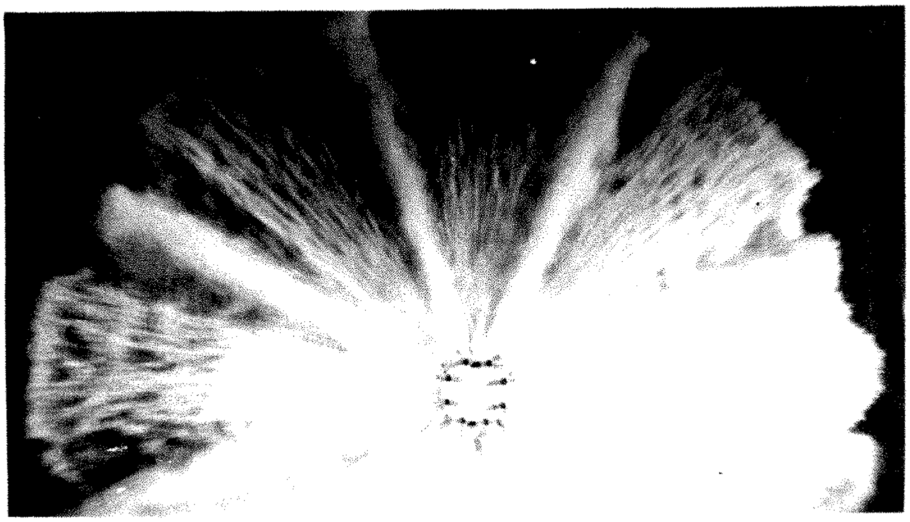
It is hardly surprising, therefore, that the HSE was much involved with its own organisation during 1975 and 1976. The report indicates that 1977 was the first year that the HSE could concentrate its efforts on new areas of research, a situation reflected in its budget. It is also pointed out that some 28% of the £8.5m was allocated to extramural work, with the aim of providing the executive with additional expertise and facilities not immediately available to it.

These are the Health and Safety Laboratories (HSL) run by the HSE. The Explosion and Flame Laboratory (EFL) is based at Buxton; the Occupational Medicine and Hygiene Laboratory at Cricklewood; and the Safety Engineering Laboratory in Sheffield.

Explosions and flames

Dr Herbert Eisner is the Explosion and Flame Laboratory's director. Outlining the work carried out at Buxton, he indicated that much of the research is concerned with the development of test methods, pointing out that "If a hazard is present, you need to discover the mechanism which caused it".

Of particular concern to EFL are hazards encountered in gases. The reason behind the EFL's interest in gas is obvious from its history. It started life over sixty years ago as the Safety in Mines Research Establishment and in an even more remote location, in Cumberland. From its inception, the laboratory has been concerned with the prevention of explosions in coal mines and the development of safe electrical equipment for use in explosive atmospheres. Research of this nature has a far wider application than that of coal mining alone: spark-proof equipment is vital in many industries. Eisner selected two at random: fork-lift trucks used in the chemical industry, and safe diesel engines which can be run in potentially dangerous atmospheres.



Discharge of water from disperser of triggered barrier.

Many government agencies are moving over to the system by which they choose at cost. The EFL does make charges at a commercial rate, although—as Eisner points out—the information provided is cheap at the price. Invaluable work has been done in the area of the testing of explosive devices for use in industry. Manufacturers of explosives have a difficult task: they are required to develop explosives which are safe for use underground, and which in many cases release an energy 10^8 times greater than that required for the ignition of any methane which may be present.

Some of the current research programmes at the EFL include computer model studies of uncontrolled vapour clouds and explosions and, following the recent grain silo accidents in the US, the explosive potential of these installations is receiving more urgent attention.

Although there has been no explosion involving coal dust in a British mine for the past fifteen years, there is no ground for complacency, according to Dr Donald Rae. Rae is one of the physcists at Buxton and is investigating automatic devices for the containment of explosions underground, and he maintains that there are occasional situations in which the stone-dust barriers in current use need to be replaced. The high rate of coal extraction in modern mining apparently makes automatic devices essential. Stone-dust barriers require a great deal of maintenance; Rae feels that the 'triggered barrier' could be the answer for the future. He and his colleagues have spent ten years developing this device, and the first will soon be installed in a British mine. At present stone-dust is tipped into the path of an explosion to 'snuff it out'. The triggered barrier uses water under high pressure to perform the same function. A thermocouple responds to the flame of the explosion, relaying the message to a pressurised nitrogen cylinder, the pressure of which is used to eject water from a second cylinder into the path of the oncoming flame.

The possible range of flame speeds

0028–0836/78/0276—0435$01.00

underground is anything between 0 4 and 3,000 m s^{-1} (detonation speed). In practice, most explosions in their early stages travel at a speed of between 40 and 400 m s^{-1}, and the barrier has been developed accordingly and will ensure that sufficient water is available to extinguish anything in this range

The NCB was swift to realise the ignition hazard posed by light metals, although mining industries in some countries have still not taken action to reduce, or indeed eliminate, the hazard—some mines in the US are known to fall into this category. Frank Powell and Roy Gregory, both working at Buxton, demonstrated all too easily how a 'spark proof' tool with a handle of aluminium, or other light metal, will produce showers of sparks if struck on a rusty steel bar. With their high affinity for oxygen, these metals, when so struck, cause a thermite reaction, generating temperatures of about 3000 °C; the sparks which are simply the visible hot fragments of reacting metals may have sufficient energy to ignite methane, and would present an ignition risk if the metals were allowed into a mine. It is with some justification therefore, that Powell and Gregory tend to be rather dismissive about the safety qualities of some 'spark proof' tools And they add that it is not only the mining industry which has been shown to be at risk: for light metal anti-corrosion electrodes have caused several explosions in oil tankers.

Safety engineering

The Inquiry into the explosion at the Flixborough Chemical plant in 1974 concluded that poorly constructed and insufficiently supported by-pass piping at the 'Nypro' plant collapsed, allowing cyclohexane vapour to escape. Ignition of the vapour produced an explosion which was responsible for the death of 28 people. The Safety Engineering Laboratory (SEL) at Sheffield played its part in the investigation The work at Sheffield included forensic studies of the failed components and materials, involved as well as tests on a simulated by-pass pipe assembly

Entering the Incidents Laboratory at SEL is rather like visiting the yard of a scrap metal dealer. lifting gear, process-plant components, mining equipment and wire ropes are strewn over the floor of the lab Jack Deakin, an engineer in the laboratory, says that most of the items were removed from the site of accidents and either had been, or were about to be, examined by the laboratory The investigations done cover fatigue and brittle fractures, defective welding, and design and maintenance problems.

But engineering is not the only concern of the Sheffield Laboratory For the past few years fatal accidents in the mining industry have remained at about 50 per annum, following a steady fall over the previous 20 years as conditions in the mines improved. Indeed, the fatal accident rate 100,000 manshifts worked was almost halved between 1958 and 1971, but since then there has been no significant improvement And the fall in fatalities has not been matched by a decline in the serious injury rate.

Dr Clive Nussey (of SEL) believes that studies of minor accidents and 'near miss' situations might well provide information to help reduce the fatal and serious injury rate. (The chemical industry has recognised for a long time that the lessons to be learned from 'near misses' are as valuable as actual accidents, particularly as the former occur so much more frequently than the latter) Nussey says that over a third of the fatal and serious injuries in the mining industry are attributable to haulage and transport And in a collaborative study on minor injuries associated with transport and handling accidents, done with the NCB and HSE's Mines Inspectorate, Nussey's laboratory found that the events leading to these injuries, or indeed to 'near misses', also appear as causes of fatal or serious injuries on transport systems. Nussey believes, therefore, that even outside the mines the frequency of these events is such that they could form the basis of early warning system to help predict where more serious injuries might occur in future

Medicine and hygiene

The Occupational Medicine and Hygiene Laboratory is the third of the HSL Laboratories and is mainly located at Cricklewood The biological monitoring work in this laboratory is under the direction of Dr David Gompertz, he is relatively new to the post, and is still in the process of developing the laboratory facilities. He admits to being "aggressive and demanding" and to being impatient to change the emphasis of the work in his laboratory. When Gompertz moved in, 85% of the work of the Occupational Medicine Laboratory was on metals and only 15% on organic chemicals, and 95% of the time was spent doing routine investigations This will change

It is envisioned that in the future only 40% of the work will deal with metals, and 60% will be concerned with organic chemicals—but this does not mean there will be less work on metals. The routine investigations will still consume most of the time—about 60%—but Gompertz says that the rest will be devoted to research and development Gompertz is receiving support from the HSE for his programme of change. Evidence of that support is provided by one of the laboratories latest acquisitions, a gas chromatograph and mass spectrometer which will be used to build up a background library of chemicals for use in the biological monitoring of workers at risk.

The Occupational Hygiene Laboratory (OHL), also at Cricklewood, is much concerned with the measurement of contaminants—such as fibrogenic materials, toxic metals, gases and vapours—in the working environment. Work at the OHL centres on developing the methodology and instruments for use in such situations One of the instruments developed there, a general-purpose tape for monitoring atmospheric chemicals, is listed in the HSE's 1977 Research Report The few tapes currently commercially available are designed to have a long shelf life and to remain stable In consequence, they can only be used for a limited range of chemicals The HSE research team has now developed a more versatile tape with a wider application Although the report devotes no more space to this development than it does to other topics, this in no way lessens the impact for occupational hygienists The institute is also about to publish details of a tape for detecting aromatic amines; and hopes to produce ones for aromatic isocyanates, phosgene and chlorine

The technology for measuring respirable dust concentrations is constantly being improved and the OHL is placing much emphasis on another of its entries in the report, a continuously recording instrument for measuring dust samples. Called SIMSLIN II — the Safety in Mines Scattered Light Instrument—it is an improved version of an ealier model SIMSLIN II is currently at the pre-production stage and is being tested in underground trials in co-operation with the NCB SIMSLIN II weighs 8 2 kg and is 42 cm long and according to the report it is 'intrinsically safe in methane atmosphere'. The instrument is able to exclude non-respirable particles from the dust intake and to measure the respirable fraction by light scattering at regular—15 s or longer—intervals. With SIMSLIN II already being manufactured by a commercial company the OHL must be fairly certain of its marketability for it asserts in the report that "the instrument should find wide application in many industries where detailed records of dust concentrations are required"

The HSE appears to be acutely conscious of the need to produce useful research findings in the field of health and safety As it is, the 1977 report forms an impressive track record for a research year, and there are unlikely to be many complaints about the chosen allocation of the HSE budget ☐

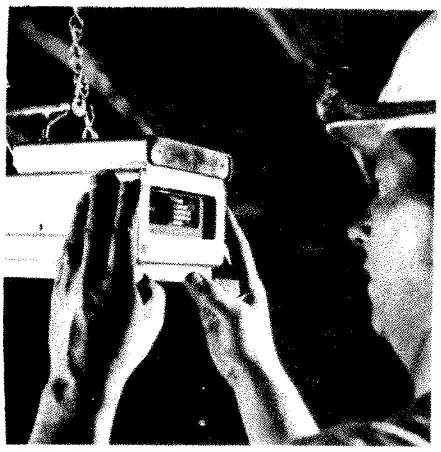
HSE's scientific mediator

On 1 July this year, Dr Ken Duncan became the third member of the triumvirate that runs the Health and Safety Executive (HSE). Duncan will be the principal person at HSE concerned with matters of biomedical research. He will combine his new work with his job of the past four years as Director of Medical Services on the staff of the HSE secretariat. Here he talks to ALASTAIR HAY.

OCCUPATIONAL medicine has been Ken Duncan's main concern for much of his working life, most of which has been spent in industry. His career began with British Rail and the South Western Gas Board. He later became chief medical officer of the United Kingdom Atomic Energy Authority and then head of health and safety at the British Steel Corporation.

Duncan has also played a part in the academic world. He is currently a visiting professor at the London School of Hygiene and Tropical Medicine, and registrar of the newly-formed Faculty of Occupational Medicine at the Royal College of Physicians. He is a former president of the Society of Occupational Medicine, has a place on the board of the Permanent Commission and International Association of Occupational Health, and is also a member of the Medical Research Council. It was on the subject of relations between the HSE and the MRC that he began his interview with *Nature*.

Duncan recalls that, when Rothschild's "transferred fund system" was implemented, the HSE found itself with some £700,000 to allocate annually to biomedical research. However, unlike the Department of Health and Social Security which was also affected by the Rothschild system, the HSE had few of its own research programmes in this field. It had to "buy itself into research," he says. "HSE's intention was to implement Rothschild by looking at specific problems. But there was one real difficulty. Very few customers had the necessary expertise to draft research protocols for specific problems." Fortunately, the MRC was on hand to help select suitable projects from the numerous proposals received.



Simslin recording the concentration of respirable airborne dust particles (see p.436).

The HSE will have to show that its £700,000 is well spent. If it fails to do so, one result, according to Duncan, will be a loss of trade union support, which could well be disastrous. The commission (HSC) is a tripartite organisation involving the Confederation of British Industry, local authority nominees and the Trades Union Congress. TUC support is obviously vital.

Duncan admits that the HSE places a heavy load on the MRC and that the council is not altogether happy with the arrangement. It is no secret that the MRC would prefer the HSE to follow the example of the DHSS on research work, but Duncan believes that the HSE has yet to reach this stage of development. Relations between the two bodies are reflected in the financial arrangements; until the HSE can assess its own research proposals, it will continue to ask the MRC for guidance, and while this is the case, the MRC has been reassured that most of HSE's research funds will be channelled through its books.

Under the terms of the Health and Safety at Work Act, the onus is on employers to prove the health and safety of each workplace. Duncan sees the HSE's role as monitoring health and safety projects carried out by industry, and cooperating with researchers "to ensure that the work is valid and in no way suspect".

He is deeply disturbed by the conflict in evidence in the United States between scientists in academic circles and those in industry. This polarisation has become so marked that in some cases neither group is prepared to accept the research results produced by the other. Academic scientists have voiced the opinion that the research work of industrial scientists in the field of toxicology is not only biased towards the companies involved, but that results have been deliberately kept secret and in some cases even destroyed. They also claim the research itself is often of poor quality. Scientists in industry have been swift in responding to these accusations. They say the charges may apply to a few companies, but not to the majority. Many have also been heard to complain that scientists in academic circles are making unrealistic and irresponsible demands upon industry for absolute safety.

Should this conflict spread to the UK, Duncan feels one of the most important functions of the HSE in the next five years could well be as mediator, by ensuring that industrial research, and in particular research into hazards, is of a reputable standard. He also indicates the importance of publishing all results even if they do not yield the "right answers". The health and safety act now makes it compulsory for employers to inform employees about risks (and for the manufacturer, installer and supplier to inform an industrial client similarly).

If the scientific integrity of the researcher could be accepted by all concerned, Duncan believes the conflict need not be so severe in Britain. He refers to the "constant dilemma" which many research workers face when only preliminary results are available. The question everyone asks, he says, is "do you publish the results or withhold the information until you have more evidence to confirm your observations?". Duncan is certain that industry would reveal more information if the response to it was not exaggerated. But he stresses that the one thing the HSE cannot do in this situation is to abet industry in 'covering up' important information. The response of a few trade unions to research on risks is still a crude one; they see it as a potential threat to jobs. Duncan is not enamoured of this response. Ultimately, however, risks will have to be evaluated rationally and this, he suggests, might be a job for the commission.

Duncan sees toxicology as one area in which the HSE will have to offer guidance to the commission for its deliberations. It is recognised that the new HSE notification schemes will generate some friction in industry, and toxicologists will be well to the fore in future controversies. The HSE's intention is to have "plenty of scientific kick" to back up its decisions, says Duncan. And the "kick" will come not only from the ranks of the HSE: the DHSS will be on hand to provide additional support. As a result of this arrangmeent, Duncan is confident that the executive will be well equipped to cope with the demands put upon it. □

correspondence

Mincingly speaking

Sir,—My good friend Ken. Mellanby (7 September, page 8) fell into the trap of assuming that a word cannot have two meanings. Mincemeat is defined in dictionaries (including the Oxford Dictionary) as either (1) ground, chopped or minced meat, (2) the mixture of raisins, apples, spices etc used on both sides of the Atlantic in mince pies. The term 'mincemeat' for ground meat may have been abbreviated to 'mince' in Huntingdon—I do not know. But, as a former Sussex man, I recall that Hilaire Belloc said that the Midlands were "sodden and unkind". I would not think of using such language myself, of course.

Yours faithfully,
THOMAS H. JUKES

University of California
Berkeley, CA, USA

mincemeat *n* [alter. of *minced meat*, fr. *minced* (past part. of ^{1}*mince*) + *meat*] 1: minced meat 2 : a finely chopped and usu. cooked mixture of raisins, apples, spices, and other ingredients with or without meat and suet 3 . something felt to resemble finely chopped meat; *specif* : a state of destruction or annihilation — used in the phrase *make mincemeat of* science of making .. of the old-time religion — F.L. Allen; making . of the inhabitants — Richard Joseph)

Geos III not enough for POLO

Sir,—Your articles on the European Space Agency (ESA) (5 October, page 355) are timely as its activities and those of its predecessor (ESRO) have not been widely known to the European scientific community: the present discussions within ESA of future programmes are greatly hampered by this ignorance. However, your statements about the polar orbiting lunar observatory (POLO) need clarifying. You mention the proposal to use the fourth Ariane test flight in 1980 to launch a lunar satellite, building this quickly and cheaply from Geos III hardware. However this is not the POLO concept as only a small part of the necessary complement of experiments to survey the whole surface of the Moon by chemical and physical sensors could be flown on this test flight.

Your report does not make clear that a mission definition study is now being undertaken so that the POLO can be a competitor in the decision as to which mission ESA will launch in 1985. In their recent report ('An approach to long range planning 1980-1990') the ESA Solar System Working Group laid great emphasis on the desirability of European involvement in studies of the Moon and planets and smaller bodies of the solar system, and it is as a result of the interest stimulated by this report that the mission definition study of POLO has been launched. This new development in ESA's thinking recognises that many European laboratories in the last decade have done fundamental work on Apollo and USSR lunar samples, and have participated in planetary missions (see 'The Moon: a new appraisal from laboratory studies and space missions'. The Royal Society. 1977. Ed. by G. Brown, G. Eglinton, S. K. Runcorn and H. C. Urey). The Ariane rocket has progressed so successfully that Europe will have in the 1980s the technology capable of launching orbiters for scientific study around Mars, the Moon and Venus.

During the preparatory study of POLO, it has been established that there are European laboratories capable of making the experimental hardware for all the various experiments which need to be done (see experiments listed in *Nature*, **265**, 197–199 (1977) Runcorn S. K. and Coleman P. J.) but there is now a great need for the European scientific community, particularly young physicists, chemists and geologists, to take these opportunities now unfolding in ESA, seriously. Potential interest from European scientists in building experiments or making use of the data to be obtained or perhaps suggesting entirely novel experiments to be done from the orbiter, which the rather closed circle of space scientists may not have envisaged, could be very helpful in the preparatory study now proceeding. (Dr G. Haskall, European Space Agency, 8-10 rue Mario Nikis, 75738 Paris Cedex 15 will supply information.)

Yours faithfully,

Chemi-osmosis and energised protons

Sir,—I write this letter to correct some impressions (2 November, page 8) left by your correspondent while describing the achievements of Dr Peter Mitchell for which the Nobel Prize was awarded. Mitchell's distinguished work in 1961 was in the development of a quantitative theory of chemi-osmosis and has been particularly used in explanation of the transduction of energy in biological systems. In this context chemi-osmosis uses a proton gradient. My contribution to this field, to which your correspondent refers most kindly, was to propose first that it was in fact energised protons which were the intermediates in energy transduction. The reference is *The Enzymes*, eds. P. D. Boyer, H. Lardy and K. Myrback, 1, 391; Acadamic Press 1959.

In 1961 I developed the idea of how energised protons might be used in systems which have diffusion control (*J. Theoret. Biol.* 1, 1; 1961) and one form of this control was independently visualised by Peter Mitchell and myself at that time. This is chemi-osmosis. Where Mitchell and I differed is that he considered this to be the actual mechanism in biological systems. Moreover he developed quantitative tests and did experiments to check his ideas. (It is also fair to add that chemi-osmosis unconnected with energy transduction and unknown to me was developed more qualitatively by Mitchell during the preceding five years. To be fair to myself, in 1961 before Mitchell's article in *Nature* **191**, 141; 1961 was written, he had read both of my papers above).

While Mitchell developed chemi-osmosis I developed an alternative more general approach to diffusion control based on my original concept of energised protons. I think you will understand that in this context I do not accept the concluding remarks by your correspondent about Popper's use of working words. It would be easy to show that Mitchell's ideas and mine could then become lost in the word "chemi-osmosis". Mitchell's theory must be examined in terms of the equations which were derived from it. As I do not accept that chemi-osmosis is a correct description of energy transduction in biology it is very important to keep names tightly associated with ideas. Clearly if in the long term my views are to predominate it is my job to show where chemi-osmosis is incorrect and where my own ideas of localised energised protons are correct. Some papers along these lines have been published and I am about to submit a detailed proposal.

The Nobel Prize has been awarded for chemi-osmosis. In that context it has been very properly awarded to Dr Peter Mitchell and I will be the last to contest this. It so happens that I do not think that it is the correct theory of the way in which energised protons (not originally asociated with chemi-osmosis, see above) are used in biological systems. We shall see.

Yours faithfully,
R. J. P. WILLIAMS

Inorganic Chemistry Laboratory,
University of Oxord, UK

US geneticists

Sir,—I wish to make two comments in connection with the article by John Douglas, 'US geneticists look to Europe for research facilities' (21 September, page 170):

- The list of sources of support of the original research leading to the procedure used in synthesising artificial genes should have included the American Cancer Society, not the National Cancer Institute.
- The penultimate paragraph cites the prospective United States patent as at least a partial reason why scientists might be doing certain genetic research in Europe.

The existence of a patent *per se* does not inhibit research in the US or elsewhere. The only basis on which this particular patent (if granted) might become a factor in the choosing of a site of research is that, as noted earlier in the article, industrial licensees of the patent will be required to follow the NIH safety guidelines for genetic-engineering.

Yours faithfully,
NIELS J. REIMERS

Office of Technology Licensing,
University of Stanford, USA

news and views

Interstellar carbon

from M. G. Edmunds

SOMETHING in interstellar space absorbs strongly at about 2200 Å. Since the discovery during rocket observations in the early 1960s of a broad absorption feature at this wavelength, more sustained access to the ultraviolet region of the spectrum by satellite observations has shown that the absorber is widespread in our own Galaxy. The detection of this 2200 Å feature in the Large Magellanic Cloud reported on page 478 of this issue of *Nature* by K. Nandy and D. M. Morgan indicates, perhaps not unexpectedly, that the absorber is a common constituent of the interstellar medium of galaxies. But the identification of the material responsible for the absorption remains in dispute. The considerable strength of the feature, normally observed by its influence on the light from a background star, implies that the absorber must be made up of one or more of the most abundant elements. Hydrogen and helium have no suitable features, and the next most abundant elements are oxygen and carbon.

Carbon in either solid or compound form seems to be the most likely candidate, and a similar absorption feature in the theoretical extinction properties of small graphite spheres was noted at the time of the first rocket observations. An elegant explanation of the exact shape of the observed feature was proposed by D. P. Gilra (*Scientific Results from OAO-2*, NASA SP-310, 1972), and this remains the most widely accepted evidence in support of the graphite sphere identification. He suggested that the absorption peak arises from the excitation of a collective mode of oscillation of the electrons, a so-called 'surface plasmon'. The match with observation is very good, provided the particles are very small (of order 0.01 μm in radius) and very spherical. Recent calculations of the expected wavelength dependence of extinction over both ultraviolet and optical spectral regions for a mix of particles of different sizes and compositions (Mathis *et. al. Astrophys. J.* **217**, 425; 1977) suggest that the exact size of the graphite spheres is not a very stringent limitation. The 2200 Å feature can still be reproduced by a distribution of graphite particles from 0.005 μm to .1 μm provided that the distribution is heavily weighted to smaller sizes. The fundamental restriction comes from the particle shape, because the wavelength and profile of the absorption feature will change significantly if the particles depart from almost perfect spheres. It may well be that the graphite component of interstellar dust is initially formed in a very spherical shape, or is perhaps subsequently modified to sphericity by collision or erosion. Yet the great anisotropy of the physical properties of graphite would lead to the expectation of a much less symmetrical linear or plate-like crystal growth. Good prospective sites for the formation of graphite dust are known—the carbon-rich atmospheres of some cool stars and the expanding, cooling ejecta of supernova explosions—but so little is known about the growth from vapour phase of small crystals under these low density conditions that no realistic predictions of grain shape can be made.

Other possible culprits for the 2200 Å feature have been proposed, and most of these again involve carbon. The detection at radio wavelengths of fairly large molecules has led F. Hoyle and N. C. Wickramasinghe to propose that a considerable fraction of interstellar carbon is in the form of complex organic molecules. The ultraviolet feature then arises by $\pi \rightarrow \pi^*$ electronic transitions in conjugated carbon bonds (*Nature* **261**, 241; 1976; **270**, 323; 1977). The organic molecules could be incorporated in or on dust particles, and the experimental detection of an absorption hump at 2200 Å in organic extract from the Murchison meteorite is evidence that a feature can be produced without requiring graphite spheres. The advantage of the bonding argument is that it removes the shape constraints on the dust which carries the molecules. Obviously detailed modelling is required to see if the shape of the observed feature can be accurately reproduced, although the authors admit that preliminary studies indicate that there is probably still a need for some contribution from graphite.

An interesting suggestion that the interstellar carbon may indeed be in solid elemental form, but as the allotrope carbyne rather than graphite, is currently being put forward by A. Webster of the Mullard Radio Astronomy Laboratory. This material (see for example, Whittaker, *Science* **200**, 763; 1978) is extremely difficult to make experimentally, and hence almost nothing is known about its physical properties. Its structure is basically of long parallel chains of conjugated carbon bonds, again giving rise to the hope that it might provide a 2200 Å feature by electronic transitions and independent of particle shape. Quantitative predictions of extinction properties will be required before the relevance of carbyne for the interstellar medium can be assessed. The (admittedly uncertain) phase diagram suggests that it might condense out before graphite in the proposed astrophysical sites of graphite formation, but it is not clear whether it would not subsequently convert to graphite on further cooling and exposure to radiation. Even if carbyne is only important as a short-lived stage in the condensation of graphite dust, this again has implications for the expected graphite dust shape, since the carbyne would probably grow as a linear structure and conversion to graphite is unlikely to produce perfect spheres.

The 2200 Å feature is not the only puzzle in the ultraviolet properties of interstellar material. The continuous extinction in the far ultraviolet considerably exceeds that which would be

---

0028–0836/78/0276—0439$01.00

expected from the general extinction of the right amount of small graphite spheres required to match the 2200Å peak. The calculations on which this conclusion is based rest on classical Mie scattering theory, and there is some evidence (still unexplained) that experimental determinations of the ultraviolet behaviour of such small particles show a much higher extinction than the theoretical prediction (Day & Hufiman *Nature* **243**, 50; 1973).

It appears that for the present, despite the qualms about growth shapes, that small graphite spheres remain the best candidate for explaining the 2200 Å absorption. Yet work on alternative explanations is very important, particularly in the hope that an absorber can be found which not only accounts for this feature, but also for many of the broad shallow absorption features found in the optical spectral region and known as the 'diffuse interstellar bands' These have been observed for many years, but still defy convincing identification. There is no evidence that graphite spheres would supply such optical features, but on the grounds of simplicity it seems unsatisfactory to invoke yet more components of the interstellar medium to explain them, particularly as additional types of dust must already be proposed to account for the observed continuous extinction over the optical spectrum.

Two-neutron transfer heavy-ion reactions

from P. J. A. Buttle

THE growth in recent years of heavy ion physics, in which target nuclei are bombarded with nuclei accelerated in a heavy ion accelerator, has led to many interesting new phenomena in nuclear physics, but as is often the case with a new field of study, has introduced many new problems. Among the simplest types of reaction which can occur is the transfer of a single nucleon from one nucleus to the other Apart from a few anomalous cases, these single nucleon transfer reactions are reasonably well understood and it has been possible to obtain useful information about the wavefunctions describing the state of the transferred nucleon in the two nuclei. Reactions in which two nucleons are transferred have been more problematical, theoretical calculations often underestimating the yield of the reactions (or the cross section) by at least an order of magnitude.

Part at least of the difficulty is that the two nucleons can be transferred either simultaneously or in two separate steps (sequentially), whereas theoretical analyses have often been optimistically confined to only one of these mechanisms. To complicate matters further, the distinction between silmultaneous and sequential transfer is not very precise, so that the inclusion of both processes in a calculation involves a certain amount of double counting Full analysis shows that a 'non-orthogonality' term should be subtracted from the amplitude to allow for this.

A recent careful study of the two neutron transfer reaction

$$^{208}\mathrm{Pb} + {}^{16}\mathrm{O} \rightarrow {}^{206}\mathrm{Pb} + {}^{18}\mathrm{O}$$

at Minnesota (Franey *et al. Phys. Rev. Lett.* **41**, 837; 1978) confirms that both simultaneous and sequential transfer are important The experiments were done at a series of energies low enough (69–73 MeV) that the Coulomb repulsion between the charged nuclei prevents nuclear collisions The relative motion of the nuclei is then well understood and the transfer of nucleons from one to the other can be investigated without having to face the complexities of a full nuclear collision. The reaction is reasonably 'well matched', that is, the transfer of energy is fairly small so that the classical trajectories followed by the nuclei are not strongly perturbed by the transfer.

The single nucleon transfer reactions

$$^{208}\mathrm{Pb} + {}^{16}\mathrm{O} \rightarrow {}^{207}\mathrm{Pb} + {}^{17}\mathrm{O}$$
$$^{206}\mathrm{Pb} + {}^{18}\mathrm{O} \rightarrow {}^{207}\mathrm{Pb} + {}^{17}\mathrm{O}$$

to a series of excited states in ^{207}Pb and ^{17}O were also studied in order that both steps in the sequential transfer be properly understood

Two types of calculation were reported; the first a semi-classical calculation (Broglia & Winther *Phys Rept* **4C**, 153; 1972) in which the relative motion of the nuclei is treated classically. This is a reasonable approximation since the wavelength for classical motion is small compared with the size of the nuclei. Simultaneous, sequential and non-orthogonality terms contribute approximately 50%, 80% and −30% of the total amplitude, and the result is in excellent agreement with experiments

The second, fully quantal calculation (second order DWBA) gave a similar ratio for the simultaneous to sequential amplitudes. The non-orthogonality term could not be calculated and was assumed to contribute in the same proportion as in the semi-classical calculation. The overall magnitudes were however smaller, leading to an underestimate of the cross section. This may indicate that the non-orthogonality correction should be smaller in the quantal calculation, or that a more sophisticated treatment of the bound state wavefunctions is needed for simultaneous transfer, as suggested by Feng, Udagawa and Tamura (*Nuclear Phys.* **A274**, 262; 1976).

The general agreement between theory and experiment for two-neutron transfer is in accord with the analysis of Feng *et al.* for calcium targets, and gives more confidence in our understanding of these well matched reactions Difficulties remain, however, for less well matched reactions which have smaller yields, and for two-proton transfer reactions where theoretical calculations still underestimate experimental results by a large factor. ☐

Pleiotypic effects of hormones

from Robert Shields

LONG before the dawn of molecular biology endocrinologists were aware that steroid hormones exert generalised trophic effects on their target tissues. For instance, oestrogens promote the growth and development of the uterus, glucocorticoids are trophic in the liver and androgens affect male accessory tissues such as the prostate and seminal vesicle. However, these effects are often conveniently forgotten by biologists attempting to understand the action of steroids at the molecular level Concentrating their efforts on the effects of steroids on a handful of specific proteins such as the egg white proteins of the chick oviduct, workers in this field have made impressive progress culminating in the successful cloning of the ovalbumin gene (Dugaiczyk *et al Nature* **274**, 328; 1978; Mandel *et al. Cell* **14**, 641, 1978) It will not be long before we understand how steroids act at the molecular level in at least a few restricted cases. The time has now come when the more general (and equally important) trophic effects of steroids should be re-examined

While the general trophic (or pleio-

Robert Shields is at the Colworth Laboratory, Unilever Research, Bedford.

0028–0836/78/0276—0440$01.00

typic) effects of steroids may be the end product of a series of events involving the production of a few new mRNAs (and hence a few new proteins) it seems likely that additional mechanisms are involved. The view that the general trophic effects of steroids and their specific effects on a few proteins may have a different basis is reinforced by the observation that general and specific effects may become separated. For instance, hydrocortisone has a general anabolic effect on the liver and also promotes the production of a specific set of proteins, principally those involved in gluconeogenesis. In hepatoma cells, however, the trophic effect is absent, but the specific effect on the production of a few proteins including tyrosine transaminase is still present (Ivarie & O'Farrell *Cell* **13**, 41; 1978). Until recently there were few well-studied cases of the reverse situation where the general trophic effect of steroids could be observed without concomitant specific effects. Recent work on the rat seminal vesicle suggests that this may be a good system to do just that.

About 30% of the protein synthesised in the rat seminal vesicle is accounted for by two secreted glycoproteins of the seminal plasma. The synthesis of these proteins is controlled by testosterone since their synthetic rates fall after castration and rise after hormone treatment (Higgins *et al. Biochem. J.* **158**, 271; 1976). So far this looks just like another case of specific protein induction by steroid hormones Where these results are interesting is that the synthetic rates of these proteins follow the overall rate of protein synthesis which in turn parallels total mRNA levels (Higgins & Burchell *Biochem. J.* **174**, 543; 1978). So in this case the rise (or fall) of the levels of the mRNAs of these two proteins is not a consequence of the specific rise (or fall) of their respective mRNAs (as is the case with ovalbumin for instance) but is a result of some general change in metabolism of the entire spectrum of mRNAs in the tissue. Careful analysis of the sequence complexity of the mRNAs isolated from the tissue in different hormonal states confirms this conclusion (Higgins *et al. Eur. J. Biochem* in the press) and furthermore, these changes in total mRNA levels also parallel changes in the total RNA content of the organ (Higgins & Burchell *Biochem. J. op. cit.*). Since mRNA accounts for only a fraction of the total RNA in the cell this result shows that in this tissue at least, androgens may regulate the overall levels of RNA transcription rather than the transcription of a severely limited number of genes.

These results are strong evidence that androgens act to produce the trophic response in the seminal vesicle without inducing new mRNA species; however, in other tissues androgens are capable of inducing new proteins. In the ventral prostate, for instance, androgens control the synthesis of four major proteins that, like the seminal vesicle proteins, are glycoproteins secreted into the seminal plasma (Hayns *FEBS Lett* **81**, 43; 1977; Parker *et al. Biochem. J.* **170**, 115; 1978). In distinct contrast to the situation in the seminal vesicle these proteins are not regulated by general changes in overall mRNA synthesis but rather by specific effects on their individual genes (Parker & Mainwaring *Cell* **12**, 401; 1977; Hayns *et al. Biochem. biophys. Res. Commun.* **77**, 1492; 1977; Parker & Scrace *Eur. J. Biochem.* **85**, 399; 1978).

These results show that alterations in the synthesis of major secretory proteins may be brought about by two different means, one is the (dare one say) more traditional alteration in the levels of specific mRNAs coding for those proteins, and the other is through modulation of the production of RNA as a whole. Quite why these two different strategies are adopted for the same hormone in functionally closely related tissues of the same animal is however far from clear. ☐

Amorphous silicon

from a Correspondent

The letter published in this issue of *Nature* (page 482) by S. R Ovshinsky and A Madan highlights the intense activity in laboratories all over the world seeking to exploit the potentialities of amorphous silicon for photovoltaic solar cells. For a solar cell which does not make use of lenses or mirrors to concentrate the Sun's radiation, it is obviously necessary to cover a very large area, and the outstanding advantage of deposited films of amorphous silicon is their cheapness, compared with the single crystals of the usual silicon technology.

The possibility of using amorphous silicon is a very recent development. It is only 15 to 20 years since it was recognised that glasses and amorphous materials generally have conduction and valence bands very similar to those in crystals The early work of Kolomiets and coworkers in Leningrad on the semiconducting chalcogenide glasses, for instance As_2Te_3, showed that, unlike crystals, these glassy semiconductors cannot be doped. The reason seems to be that in a glass any atom takes up a configuration such that all its outer electrons form bonds with nearest neighbours. Thus As has three neighbours in the glass, Te two and if Ge is added we expect it to have four Amorphous silicon is not of course a glass, in the sense that it cannot be prepared from the melt; but films prepared by deposition have the normal fourfold coordinations and behave as semiconductors. Properties of evaporated or sputtered films are not the same as those that would be expected from a continuous random network, in which every atom is bonded to four neighbours. For instance, electron paramagnetic resonance investigations reveal a high concentration of unpaired spins, presumably located at dangling bonds occurring on silicon atoms bonded to only three neighbours. Moreover these and other places where the continuous random network is broken produce what are called 'deep states in the gap', that is to say points where an electron may be trapped with a value of its energy somewhere midway between the conduction and valence bands. Such states, as also in crystalline semiconductors, act as recombination centres; if an electron and the corresponding positive hole are formed by the absorption of radiation, they recombine much faster in the neighbourhood of one of these deep states, which allows the electron to get rid of its energy in two steps. In fact, so rapid is the recombination in evaporated films that it is difficult to observe a photocurrent.

The Dundee school under W. Spear, which included at that time the junior author of the paper under discussion, showed that in films prepared by the deposition of silane (SiH_4) from a flow discharge, the number of these deep states could be very much reduced, so that a significant photocurrent could be observed. There has been some dispute about why this is so but it now seems reasonably certain that, instead of dangling bonds, Si-H bonds are formed, which do not give rise to states in the gap. The films appear to contain 5% of hydrogen or more and if the hydrogen is introduced in other ways the properties are similar. Some deep states, however, remain; there has been much speculation as to their nature, and also much effort to reduce their number, so as to reduce the rate of recombination.

Now the paper by Ovshinsky and Madan claims that fluorine will do all that hydrogen did and more; it reduces the number of states in the gap considerably more than hydrogen does, and gives greater stability. The importance of this lies in the discovery by the Dundee group a few years ago that, unlike Kolomiets' glasses, one can dope hydrogenated amorphous silicon, for instance by adding phosgene to the silane Some, but not all, of the phosphorus appears to go in with fourfold coordination, and this produces donors.

It has not yet proved possible to incorporate a concentration of donors greater than the concentrations of states in the gap, and therefore the donors lose all their electrons to these states. But the Fermi energy is thereby raised and can be brought quite near to the bottom of the conduction band. And similarly, by doping with boron, it can be brought near to the edge of the valence band. It is thus possible to produce a p–n junction, or a Schottky barrier, and thus a photovoltaic cell.

From these results from Ovshinsky's laboratory, it seems then that this can be done with less doping and greater stability by replacing hydrogen by fluorine. This may turn out to be quite an important step on the long road to an efficient solar cell. □

Vertebrate skin

from R. I. C. Spearman

THE successful investigation of any organ system involves many different disciplines. This was especially evident at a recent symposium on the 'Skin of Vertebrates'* held recently in London.

R. J. Roberts (University of Stirling) and A. Bullock (Scottish Marine Biological Association, Oban) have found that in teleost fish the epidermal cells are mitotically active at all levels. This is in contrast to mammals, in which cell division is normally limited to the basal layer. In consequence, skin wound healing in fish occurs without the need for a preliminary burst of mitotic activity as seen in mammalian epidermis.

A. M. Lucas (Michigan State University) and A. G. Matoltsy (State University, Boston) showed that chicken epidermis is peculiar in that appreciable free lipids are endosecreted into the cytoplasm in addition to keratin. In contrast, mammalian epidermal cells produce little free lipid except in the sebaceous glands. R. Wrench (University College Hospital Medical School, London) has found extensive cytolysis in chicken epidermis as in sebaceous glands and she suggested that chicken epidermis is intermediate in type between the keratin-forming mammalian epidermis and lipid-secreting skin glands.

Studies on the supramolecular structure of the hair keratin complex which is constructed from many different proteins have made major advances in the past few years with long amino-acid sequences now known for some of the constituent proteins. For many years it had been thought that disulphide linkages stabilise keratins by forming cross-links between protein chains. However, R. D. B. Fraser (CSIRO, Melbourne) pointed out that there now seem to be very few disulphide cross linkages and most disulphide bonds link different points on the same chain. Nevertheless, reducing agents which break these intra-chain bonds, such as depilatory agents, soften hair keratins. How such intrachain linkages can stabilise arrangements between adjacent protein chains is not clear, but is of importance in the bonding of high molecular substances in general.

Since the turn of the century it has been known that the nerves to a tissue have some stimulatory effect on cell growth. This was first noticed in cases of gunshot wounds in which the severance of nerves to the hand had slowed down the rate of nail growth. The work of M. Singer (Case Western University, Ohio) and his colleagues on the action of nerves on limb regeneration in amphibia showed that both motor and sensory neurones promote epidermal cell division, RNA transcription and protein synthesis. The active agent has been found to be a protein which has been isolated from nerves.

Both fetal skin differentiation and adult modulation depend on interactions between dermis and epidermis. This has been studied using recombinants of dermis and epidermis from different sites. P. F. Goetinck (Connecticut State University) has found that some genes for keratinised structures act on the dermal cell transmitter of the inductor stimulus and others on the epidermal cell receiver. P. Sengel (University of Grenoble) showed that in embryonic life both the regional epidermal morphology and the particular keratin proteins formed by epidermal cells are dependent on induction by dermal cells. This is even true of recombinants between fetal mouse epidermis and chicken dermis, and so the ability of dermal cells to control epidermal functions can be transmitted across zoological class barriers. The epidermis retains some intrinsic rhythmic activity as in the sloughing cycle of snakes and lizards.

The work of A. W. Poole (Rutgers University, New Jersey) also using tissue recombinant methods has shown numerous interactions between melanocytes and epidermal cells of the hair follicle. Thus, some mutant genes which alter coat coloration act directly through the melanocytes and others act on the hair formative cells to modify the melanin pigmentation. D. T. Parkin (University of Nottingham) studied pigmentation polymorphism from another viewpoint; the effects of ecology and sexual selection on population genetics. A good example of this is the changing pigmentary patterns of pigeons seen in city streets.

As A. Iggo (Royal Dick School of Veterinary Studies, Edinburgh) pointed out in a final session devoted to neural sensation, to understand the functioning of a sensory receptor it is necessary to study the electrical activity of an efferent nerve in response to different specific stimuli, which must then be correlated with histological findings. There is good evidence that the mammalian Pacinian corpuscle and the Meissner corpuscle are pressure and touch receptors respectively, and the fact that separate sensory areas in the brain are present for heat and cold would indicate special receptors for thermal senses, although the physiological work on these is incomplete. The suggestion put forward some 20 years ago that there are no specific sensory receptors has prompted extensive research on the subject by those who believe in specificity. However, various speakers showed that in all vertebrate classes microscopy of sensory receptors has greatly outstripped physiology, and it will be some years before we fully understand skin sensation, even in mammals. □

R. I. C. Spearman is in the Department of Dermatology, University College Hospital Medical School, London.

*Held on 25–27 September and organised by the Linnean Society of London in conjunction with the British Association of Dermatologists. The Proceedings will be published for the Linnean Society by Academic Press.

Accuracy in the transmission of biological information

from a Correspondent

THE 'recognition' of one biological molecule by another has long been acknowledged to be one of the fundamental physical principles of biology. In all cases the recognition is a first step, preceding a subsequent reaction in which the correct substrate reacts further along a path from which incorrect substrates must be excluded.

More recently it has become possible to describe in quantitative terms the correctness of the recognition using an error level parameter, which expresses the ratio of the numbers of correct and incorrect substrates reacting. The error level can in many cases be measured, for example by offering *in vitro* the correct and incorrect substrate in equal amounts and examining the formation of correct and incorrect products. Typical error levels are, for protein synthesis from mRNA, 1 in 10^4 (one

---

*EMBO Workshop, 'Accuracy', was held in Grignon, France, on 12–15 September, 1978 and organised by Dr Jacques Ninio.

0028-0836/78/0276—0442$01.00

wrong amino acid incorporated for every 10^4 right ones) and for DNA replication 1 in 3×10^4. *In vivo* the error level in protein synthesis can be measured by observing a mutant in which the gene for a particular enzyme is blocked by a nonsense mutation; the appearance of small amounts of this enzyme in spite of the mutation gives a measure of the rate at which the nonsense is misread as sense.

Error levels found *in vivo* are often lower than those found *in vitro* which means that (neglecting artefacts of extraction) the organism can and does reduce its error level by increasing the complexity of the recognition process —spontaneous mutation rates fall in the range of 1 wrong base for every 10^7 to 10^{11} right ones. The error levels expected can also be predicted thermodynamically by appeal to the relationship between order and entropy: the selection of a correct substrate rather than a random one involves an increase in the amount of order in the biological system and is therefore thermodynamically unfavourable, unless other factors can be brought into play. These factors are, in part, well known: the Watson-Crick interaction in DNA replication, surface complementarity between enzyme and substrate, codon-anticodon binding on the ribosome. Since the energy involved in the selection is often known (for example, the difference between the energies of formation of a correctly-matched and a mismatched Watson-Crick pair) the error level can be predicted using simple thermodynamics. Such predicted error levels are very frequently orders of magnitude higher (that is, worse) than those achieved in cells, demonstrating yet another feat of nature which chemists can at present neither reproduce nor properly explain.

In the hope that this problem might, however, yield one day to the combined onslaught of interested mathematicians, physicists, chemists, biochemists and biologists, a meeting on 'Accuracy' was held recently*. Of principal interest were problems such as those outlined above—DNA polymerisation, protein synthesis, codon recognition, information and its relation to thermodynamics and kinetics —but the meeting also included related topics such as antibody specificity, accuracy and evolution, protein degradation and ageing.

The greatest interest was aroused by subjects relating to the central problem of molecular biology—the transmission of hereditary information over many generations of DNA and the realisation of this information in the synthesis of protein. To explain the low error levels seen in these processes, the idea of 'proofreading', has been postulated by Ninio and Hopfield (Ninio *J. molec. Biol.* **84,** 297; 1974; Hopfield *Proc. natn. Acad. Sci. U.S.A.* **71,**; 4135; 1974). They have suggested that in cases where a low error level is important the bound substrate is double-checked in a second recognition step, and rejected if it is the wrong one.

Proofreading may take place in many ways, so that according to C. Kurland (Uppsala) "we now have more theories to explain accuracy in protein synthesis than experimental results to test them." However, the proofreading theory does make falsifiable predictions, one of which is that the offer of a great excess of wrong substrate should result in a high turnover of the first recognition step, with rejection of the wrong product at the second. This has been observed by R. Thompson (University of Pennsylvania, Philadelphia) who compared the amounts of energy-rich triphosphate consumed when an artificial mRNA was used in the synthesis of the correct or (under forcing conditions) the incorrect polypeptide. For every incorrect amino acid incorporated around 30 triphosphate molecules were hydrolysed, implying that this number of incorrect amino acid molecules is eliminated at the second recognition (proofreading) step. The incorporation of the correct amino acid, which is not rejected at the proofreading step, proceeds of course much more rapidly and less wastefully.

Other forms of proofreading postulated include one by F. von der Haar and F. Cramer (University of Göttingen), in which the chemical environment of the recognition site enhances the accuracy of the recognition ('chemical proofreading'). In

Bronze Age honey

from Peter D. Moore

THE analysis of pollen grains from samples of honey is now a commonly used technique for determining what plants are used by foraging bees. It has recently been put to a rather unexpected use by Dickson (*Antiquity* **52,** 108; 1978) in the analysis of materials from a Scottish Bronze Age barrow at Ashgrove, Fife.

Within a burial cist a large quantity of decomposed plant material was found, containing the fruits of birch and seeds of rushes, together with mosses including *Sphagnum*. Over the skeleton there was a deposit of black crumbly material which, when subjected to analysis, was found to contain pollen in the proportions 54% lime (*Tilia*), 15% meadowsweet (*Filipendula*), 8% heather (*Calluna*) and 7% plantain (*Plantago lanceolata*) as well as various other minor components. The very high values for lime are exceptional, for this tree is insect pollinated. It is therefore unlikely that this assemblage represents the contemporaneous pollen fallout when the burial took place.

Dickson considers two possible explanations. It is conceivable that flowers were placed within the tomb and, since lime and meadowsweet both flower in July, their presence together is reasonable. Glob (*The Mound People*, 61, Faber and Faber, 1970) describes the use of flowers in the Bronze Age burials of Denmark. Yarrow (*Achillea millefolium*) was found in an oak coffin and this plant was used extensively both for foretelling the future and for healing wounds. No such significance is attached to lime or meadowsweet.

An alternative explanation, which Dickson favours, is that an overturned beaker also found in the burial may have contained honey or mead which had originally been produced from lime flowers. This would also explain the presence of meadowsweet (medesweete) which was widely used as an additive to mead. Dickson has found support for his argument in the analysis of scrapings from the outside and inside surfaces of the beaker. Only the inside contained lime and meadowsweet pollen, the greatest concentration being upon the lower surface of the tipped vessel. It therefore seems certain that the beaker contained honey or a honey derivative, making it the oldest record of honey in Britain, with a radiocarbon date of 3046 ± 150 b.p.

Dickson is inclined to believe that the honey was imported either from England, where lime was a far commoner tree in Bronze Age times (judging from the level of its pollen in peats and lake sediments) or even from Denmark, where Bronze Age honey has previously been recorded. There is, however, no firm evidence upon which to come to a conclusion. A single lime tree in the vicinity of a hive could account for the pollen assemblage, and lime would be capable of flowering in Fife even if it could not set ripe fruit. So the possibility still remains that this first Scottish honey was home produced.

Peter D. Moore is a senior lecturer in the Department of Plant Sciences, King's College, London.

0028–0836/78/0276—0443$01.00

another, postulated by A. R. Fersht (Imperial College, London) the amino acylation site rejects competing amino acids which are larger than the correct substrate but accepts smaller amino acids. These pass to a second, hydrolytic site which, again on steric grounds, rejects the correct substrate but destroys the reaction product formed with the competing smaller amino acids.

This mechanism has been dubbed 'double sieve editing'. R. Mulvey (MRC Laboratory of Molecular Biology, Cambridge) presented results which indicate that this is how, for example, valyl-tRNA synthetase rejects with such efficiency competitors which differ merely by one methylene group from the correct substrate, valine.

If the occurrence of proofreading can be finally confirmed, then future work in this field will clearly include the search for non-proofreading mutants and for a molecular description of the proofreading process itself, which, in spite of its complexity, must have originated at a very early stage in the evolution of the cell. □

Carcinogen binding to DNA

from Stephen Neidle

It is now generally acknowledged that the polycyclic aromatic hydrocarbons are not directly carcinogenic but are metabolised *in vivo* to short-lived reactive species that bind to cellular macromolecules, initiating cancerous processes in some way. Most evidence indicates that DNA is the critical receptor—a conclusion strengthened by the relationship between mutagenicity and carcinogenicity indicated by 'Ames-type' bacterial test systems. Over the past few years much activity has been directed at understanding the chemistry of the interactions of such metabolites with DNA But why such events are carcinogenic remains unknown.

In the case of benzo[*a*]pyrene, an important metabolite seems to be the *trans* isomer of its 7,8-diol,9,10-epoxide derivative; this electrophilic compound has far greater mutagenic and carcinogenic activity than other isomers It binds predominantly to guanine residues in DNA, with the N2 position of the purine base being thought to be a major site of attack. (However, this picture is complicated by the recent finding of Osborne, Harvey & Brookes (*Chem.-Biol Interactions* **20**, 123, 1978) that the N7 atom of guanine is also susceptible to attack by the diol epoxide; the instability of this adduct explains why it was not detected in previous studies).

Identification of likely sites on DNA for covalent attachment of a carcinogenic molecule is a vital prerequisite for any attempt at visualisation of the conformational and structural changes induced in the DNA. Grunberger, Weinstein *et al.* have utilised such information in an examination (by means of circular dichroism spectroscopy) of the conformational properties of the dinucleoside phosphate GpU to which was bound benzo[*a*]pyrene diol epoxide, at the N2 position of the guanine base (*Biochemistry* **17**, 1278; 1978) GpU was considered to be a model for a nucleic acid; however this can only be true in a restricted sense since it cannot base-pair and thus form a fragment of double-stranded polymer. Nevertheless, the finding that the bound polycyclic hydrocarbon interacts in some (probably stacking interaction) manner with the uracil residue, is of interest and some significance As Grunberger *et al.* point out, such an interaction profoundly alters the conformation of the molecule around the guanine–sugar linkage, such that if it were in a double strand the guanine would be forced out of its base-pairing position Grunberger, Weinstein *et al* have previously shown (*Biochemistry* **16**, 3127; 1977) that benzo[*a*]pyrene diol expoxide–modified DNA has small local regions of denaturation and instability, as instanced by increased sensitivity to S_1 nuclease attack relative to native DNA.

These molecular concepts have now been taken a step further by Drinkwater, Miller and Yang (*Cancer Res* **38**, 3247, 1978) who have examined the binding and mutagenic behaviour of a number of aromatic electrophilic carcinogens. These ranged from the potent benzo[*a*]pyrene diol epoxide to simple ethylene oxide–aromatic derivatives. Reasoning that the planar aromatic groups common to such molecules could well intercalate into DNA (an old, but hitherto largely discredited theory), Drinkwater *et al.* measured the unwinding induced in closed circular supercoiled SV40 DNA. This technique is widely used as a tool in the investigation of known intercalative drugs such as ethidium bromide, proflavine and actinomycin Unwinding and consequent reversal of supercoiling is considered to be diagnostic for intercalative binding Such an effect was observed for almost all the compounds studied, although with striking differences in unwinding activity between the diol epoxide and 1-pyrenyloxirane on the one hand, and such compounds as 7-benzanthryloxirane on the other. Interestingly, a strong positive correlation was found between unwinding ability, and frame-shift mutagenic activity (in a *Salmonella* Ames test) for the range of compounds tested Overall, the results of Drinkwater *et al.* clearly point to local unwinding of DNA being the consequence of the covalent binding of an active compound. They have used this information as the basis for a plausible molecular model for the structure of the DNA adduct In agreement with the notion of local denaturation at the binding site, the residue to which for example, benzo[*a*]pyrene diol epoxide is bound (be it at the N2,N7 or even C8 positions), becomes destacked from its adjacent bases and thus protrudes to some extent The aromatic part of the carcinogen is postulated to intercalate between the adjacent bases, in a similar way to the non-covalently-bound intercalating drugs. Confirmation of this model in detail must await a definitive X-ray structure analysis of, say, a carcinogen–deoxyoligonucleotide complex. The visualisation of drug–nucleic acid binding in this way is currently a topic of lively interest; it is to be hoped however that in the case of covalently-bound carcinogens, the pitfalls of extrapolating from relatively simple model complexes to polymers, will be adequately perceived

That guanine residues are the major target in DNA for diol epoxide attack, is now well established; however what is rather less clear is whether such bindings themselves are the major carcinogenic events, or indeed what relationship they have to such events The complexity of the situation is emphasised by the recent work of Kakefuda and Yamamoto (*Proc natn Acad Sci U.S A* **75**, 415; 1978) who have also examined benzo[*a*]pyrene diol epoxide modification of DNA They, like Drinkwater *et al.* observed local unwinding of closed circular DNA. However, analysis of the S_1 nuclease-treated product showed that predominantly adenine, and not guanine residues, were modified so as to cause local unwinding-induced denaturation, even though the latter bases were the major sites for actual binding of carcinogen. Furthermore, examination of double-stranded synthetic polynucleotide–carcinogen complexes showed that only the A-T one was S_1 sensitive Kakefuda and Yamamoto thus suggest that there are (at least) two categories of base modification, adenine involvement producing local unwinding and base-pair cleavage, and guanine attachment, with an altogether less drastic resultant However, the general features of the molecular model proposed by Drink-

Stephen Neidle is in the Department of Biophysics, King's College London water, *et al.*, are unaffected by any such controversies concerning the precise nature of the carcinogenic binding site, and so may well be found to be roughly correct. ☐

The sequence of *E. coli* 16S ribosomal RNA

from Richard Brimacombe

THE development of rapid gel techniques for sequencing nucleic acids has provoked a scramble to finalise the sequences of the *E. coli* ribosomal RNA molecules. Several research groups have taken part in this race, and two complete sequences of the 16S RNA have just been published. Pride of place goes to the Californian group (Brosius, Palmer, Kennedy & Noller, *Proc. natn. Acad. Sci. U.S.A.* **75**, 4801; 1978) whose sequence was determined from a plasmid DNA containing one of the 16S ribosomal RNA genes, using the DNA techniques of Sanger and Coulson (*J. molec. Biol.* **94**, 441; 1975) and of Maxam and Gilbert (*Proc. natn. Acad. Sci. U.S.A.* **74**, 560; 1977). This sequence was first reported at the EMBO ribosome workshop in Salamanca in June (see *News and Views* **247**, 743; 1978), and it has been closely followed into print by a complete sequence from the Strasbourg group who presented a partial sequence based on gel data in Salamanca, which has since been finalised (Carbon, Ehresmann, Ehresmann & Ebel, *FEBS Lett.* **94**, 152; 1978).

This latter sequence, obtained entirely independently and without so much as a mention of the Californian group, is derived from a direct analysis of RNA-fragments, using the technique first applied to a polyribonucleotide by Donis-Keller *et al.* (*Nucleic Acids Res.* **4**, 2527 (1977)).

Publication of these two sequences closes a subject which has been a matter of controversy for some years. Work on the 16S sequence using classical techniques was initiated by the Strasbourg group about 10 years ago, and led, after some preliminary papers, to the publication of a detailed oligonucleotide catalogue (Fellner *et al. Biochimie* **54**, 853; 1972) and to a first tentative sequence of the molecule (Ehresmann *et al.* *Biochimie* **54**, 901; 1972). However, two years later, a paper appeared from Woese's group in Illinois (Uchida *et al. J. molec. Evol.* **3**, 63; 1974) which claimed that over 50% of the ribonuclease T_1 sequences published by the Strasbourg group for oligonucleotides of eight or more bases in length were incorrect, and this was shortly followed by a second confirmatory paper by the same group (Magrum *et al. Nature* **257**, 423; 1975). At about this time the Strasbourgers went to press with a new version of the 16S sequence (Ehresmann *et al. Biochimie* **57**, 711; 1975). This sequence, which claimed to be 90–95% complete, was very considerably modified with respect to the 1972 version, and some but by no means all of the T_1-oligonucleotide sequences were altered to agree with those of Woese's group. At this stage about 25% of the T_1-oligonucleotides remained to be finally ordered within the sequence, but there were also queries being raised concerning some of the existing orderings (see for example Noller *Biochemistry* **13**, 4694; 1974).

The next version of the Strasbourg sequence appeared in 1977 (Ehresmann *et al. FEBS Lett.* **84**, 1977), and contained a number of substantial improvements. Additional information was given for nucleotides in regions totalling over 300 bases, the number of T_1-oligonucleotides remaining not finally ordered was reduced to a total of just over 200 bases, and almost all of the T_1-oligonucleotide sequences were in agreement with Woese's data. At this stage, recognising that application of the classical methodology was becoming subject to a law of rapidly diminishing returns, the Strasbourg group turned their attention to gel sequencing technology, and have now completed the sequence as quoted above. In this final version, all the T_1-oligonucleotides are ordered and in addition there are alterations to sequences involving a total of almost 200 bases with respect of the 1977 data, which of course brings us to the crucial question—how well does this latest RNA sequence agree with the DNA sequence obtained by Noller's group? And the answer is, the agreement is excellent. The Californian sequence is 1,541 bases long, the Strasbourg sequence 1,542 bases, and within this whole length there are (by my count) only eight single-base discrepancies. The data agree also with sequences at the 3′ and 5′ ends of the molecule obtained by Young and Steitz (*Proc. natn. Acad. Sci. U.S.A.* **75**, 3593; 1978), and all of the Woese T_1-oligonucleotide sequences (with one possible exception, containing one of the eight above-mentioned disputed bases) are correct. So everybody should be happy, and the way is now clear for serious attempts to be made to determine the secondary and tertiary structure of the molecule.

It is perhaps worthwhile to consider very briefly here the relative merits of the DNA compared with the RNA gel methodology for the sequencing of long RNA molecules. Aside from the purely technical viewpoint (where any comparison of the two sets of sequencing data is difficult, since the Strasbourg publication contains no experimental documentation), there are several points to consider. First, the DNA method gives the sequence of a single cistron, whereas the RNA method gives the 'average' of all the cistrons for the RNA molecule concerned; this undoubtedly accounts for the small but significant number of heterogeneities observed in the 16S RNA by the Strasbourg group. Second, the DNA method has an obvious advantage in allowing the use of restriction enzymes to generate the fragments for sequencing; in the RNA method, the production of suitable fragments is a rather hit-and-miss affair, although here it is noteworthy that the Strasbourg group have for this purpose made good use of the double-strand-specific cobra venom nucelase of Vassilenko and Ryte (*Biokhimia* **40**, 578; 1975). Third, while the DNA method is for this last reason certainly the cleanest and quickest for sequencing the whole molecule (once the appropriate cistron has ben isolated), the RNA method is likely to prove most useful for people working with ribosomes or similar particles and wanting a rapid analysis of a particular region of the structure. Finally, it should not be forgotten that the classical methods of oligonucleotide analysis are still needed, both to establish the nature and location of any post-transcriptional modifications such as methylation, and—particularly in the case of the RNA gel method, as has been clearly shown in a similar sequencing study by Gross *et al.* (*Nature* **273**, 203; 1978)—to confirm the sequence. ☐

Meteorology over the tropical oceans

from D. B. Shaw

A CONFERENCE on meteorology over the tropical oceans was held in London during August this year.* By its very nature, meteorology is a science requiring international cooperation and it was fitting that the conference was jointly arranged by the Royal

---

*The proceedings of the conference, in which the current state of the science is reviewed by ten leading authorities in their fields, are to be published early in 1979 by the Royal Meteorological Society, James Glaisher House, Grenville Place, Bracknell, Berkshire

0028-0836/78/0276—0445$01 00

Meteorological Society, the American Meteorological Society, the Deutsche Meteorologische Gesellschaft and the Royal Society. One of the main purposes of the conference was to provide a platform for the presentation of research related to GATE, the GARP (Global Atmospheric Research Programme) Atlantic Tropical Experiment. The field phase of GATE was completed in 1974, and has been described by Mason (*Nature* **255**, 17; 1975). Since then various designated data centres have been processing the data to make them available to the meteorological community at large. Much of that work is now completed and many research projects making use of the data are now underway. The conference provided an opportunity to assess the progress that has been made in tropical meteorology in the past few years and to identify the outstanding problems.

Central to the purpose of GATE was the problem of scale interaction—the way in which convection, which is a vital heat transfer process in low latitudes, acts on and reacts to the larger scale flows of the tropical atmosphere. A fundamental obstacle in understanding this interaction is the relatively small scale of convective processes. Deep penetrative convective towers occupy only a tiny fraction (about 1%) of the tropical atmosphere. The standard observational network cannot hope to give an adequate account of such small scales of motion. They also present a difficulty to the numerical modeller. Most numerical models of the atmosphere have a spatial resolution too coarse to resolve convective processes explicitly. Their effects are simulated, or parameterised, by idealised formulations which are designed to represent the effect, not of an individual convective cell, but of the hypothetical ensemble of cells acting in the region represented by each of the model's grid points.

As a result of GATE the meteorologist now has, for the first time, a fairly detailed description of the atmosphere on scales from the synoptic down to the convective, for part of the tropics at least. The three-dimensional structure of the large scale (~2500 km) travelling disturbances over West Africa and the East Atlantic has now been well documented. These easterly waves, usually found in the months from June to October, have associated with them marked convective activity which is generally found in the region ahead and slightly to the south of the vorticity centre of the disturbance. From a consideration of energy exchange processes it can be deduced that the latent heat release in the convection plays an important part in the development of the wave over West Africa. The role of convection later in the life cycle of the disturbance (that is, over the ocean) is less clear. Of course the convective mechanism is not to be seen purely as a forcing action on the larger scale flow; the convection is itself responding to conditions of the large scale flow.

Hurricanes that occur in the Caribbean can sometimes be seen to develop from the easterly waves with their origins over West Africa. In terms of maintenance of the atmospheric global circulation hurricanes are thought not to have a major role. They do, however, have a large local impact and are the most destructive type of weather system. An examination of hurricane records for the past 20 years reveals interesting features. Two thirds of all tropical cyclones form in the northern hemisphere. Tropical cyclones, which may or may not develop full hurricane strength, do not form in the immediate vicinity of the equator, the latitude belts 5°–15° being the preferred regions. In the majority of cases their development is very close to the Inter Tropical Convergence Zone. Their temporal distribution shows preferred periods of development, not just in seasonal terms but on a time scale of 10–20 days, probably in response to variations on the same time scale in the large scale tropical circulation. The specific criteria which influence development of an individual cyclone are seen to be a combination of thermal and dynamical conditions. Thermal instability in the vertical is not the *sine qua non* for cyclone development. Low level cyclonic circulation—and an upper tropospheric counter circulation—are seen to be particularly relevant to development.

The use of numerical models of the atmosphere for weather prediction is now commonplace in many national meteorological services outside the tropics. The application of such models in the tropics is more problematical because of the subtle nature of the balance between wind and pressure fields in equatorial regions. However, using initial conditions derived from GATE data, encouragingly good numerical forecasts out to a few days have been made by groups in both the USA and the UK. It would seem that such forecasts have similar quality, in terms of wave movement and rainfall patterns, as the operational models of middle latitudes. The extent to which parameterisations used in such models are capable of adequately representing sub grid scale processes remains an open question. □

A hundred years ago

American Jurassic Dinosaurs.—Prof. O. C. Marsh publishes in the current number (November) of the *American Journal of Science and Arts* the principal characters of some new species of dinosaurs. On the flanks of the Rocky Mountains a narrow belt can be traced for several hundred miles, which is always marked by the bones of gigantic dinosaurs. The strata consist mainly of estuary deposits of shale and sandstone, and the horizon is clearly upper Jurassic; the dinosaurian remains in this series of strata are mostly of enormous size, and indicate the largest land animals hitherto known. One new species (*Atlantosaurus immanis*) must have been at least eighty feet in length and several others nearly equalled it in bulk. With these monsters occur the most diminutive dinosaurs yet found, one (Nanosaurus) not being larger than a cat. Some of these new forms differ so widely from typical dinosauria that Prof. Marsh has established a new sub-order to receive them, called Sauropida, from the general character of the feet. They are the least specialised forms of the order, and in some of their characters show such an approach to the mesozoic crocodiles as to suggest a common ancestry at no very remote period. In them the front and hind limbs are nearly equal in size; the feet are plantigrade with five toes on each foot. The carpal and tarsal bones are distinct; the precaudal vertebræ contain large, apparently pneumatic cavities; the sacral vertebræ do not exceed four, and each supports its own transverse process. The public bones unite in front by a ventral symphisis; the limb bones are solid. One of the species described and partly figured in Prof. Marsh's paper is called *Morosaurus grandis*; when alive it was about forty feet in length; it walked on all four legs, was probably very sluggish in its movements, and had a brain proportionally smaller than any known vertebrate.

Prof. Wurtz was charged some time since by the French Minister of Public Instruction, to make an inquiry into the organisation of the laboratories and practical instruction given in the several universities of Germany and Austro-Hungary. Prof. Wurtz accordingly made several journeys to the great seats of learning in these two countries, and the *Journal Officiel* of last Saturday publishes at full length his report. Prof. Wurtz insists strongly on the danger of creating large establishments, where students are taught something of everything, and on the necessity of creating special foci for every large section of experimental science. He shows the advantage of special institutes, and insists upon the organisation of chemical, physical, physiological, anatomical, and pathological institutions such as flourish on the other side of the Rhine.

review article

A diagram of evolution

C. D. Darlington

Botany School, University of Oxford, Oxford, UK

Recent developments in molecular genetics have made it possible to re-examine the question of the relationship between chromosomes and organisms, and heredity and evolution, in the light of what is now known about the molecular basis of all of them.

OUR methods of studying chromosomes effectively and of breeding organisms experimentally were discovered by separate paths and only later did the two kinds of enquiry combine to reveal the bases of heredity and evolution. For half a century they had proceeded in parallel resting on different assumptions and implying a different understanding of the subject which was now to be called genetics. Thus in 1932 when I came to summarise what was known of the chromosomes I was able to argue a convincing unity in the subject. But beneath this unity I was forced to acknowledge a conflict which the chromosome theory was thought to have excluded. For the chromosomes were seen to have evolved according to rules of their own not clearly related to any properties of the organisms whose heredity they were supposed to be carrying[1].

The development of genetics in the past 40 years has confirmed the unity of the subject but it has scarcely noticed this conflict within it. Over the same period, however, there has been added to the old genetics a new genetics. The microbial materials and molecular equipment allow us to ask again, more searchingly, how chromosomes and organisms, heredity and evolution, are connected and how they are separated in life; what, in short, they mean for one another.

Before the nucleus

Viruses and bacteria are not the precise ancestors of our nuclear and cellular organisms but they show us how such ancestors must have worked in several important respects. In the first place, they show us what must be the chemical basis of both heredity and development in all living things. It lies in the interaction of the two contrasted forms of nucleic acid, DNA and RNA. Evidently RNA arises from DNA in development, thereby creating the organism. But it can exist independently of DNA in the simplest viruses. Therefore in evolution it seems possible that DNA arose from RNA[2].

Second, bacteria have on a smaller scale the same linear arrangement of the nucleotides of DNA as do nuclear organisms. They have pre-nuclear chromosomes. They therefore mutate by the same rearrangements of linear sequences: substitution, duplication or loss, inversion or interchange. They recombine also by breakage and reunion of pieces of chromosomes. But they have a circular form which does not allow either the diploid state, or meiosis or crossing over as known in nuclear organisms. On the contrary their rearrangements arise from processes of conjugation, insertion and infection which are elaborately controlled by the chromosomes, by subordinate bodies, plasmids, episomes and phages, and beyond them by enzymes generated by precise nucleotide sequences or genes[3].

The results of this recombination in bacteria are less regular than in nuclear organisms and probably even more wasteful. They are achieved with a loss of inviable types, some redundancy and editing of nucleotide sequences, and overlap in activities such as are believed to occur at the higher stages of evolution[4].

Our knowledge is defective in these respects but it already reveals a third principle of supreme importance, namely that the chromosomes of bacteria are organised for two adaptive functions: they regulate the metabolism of the bacterium, that is of the organism; they also regulate their own future modes of change, that is the evolution of their heredity. This is the same duality that we already know in the post-nuclear world.

To come to a fourth connection: we cannot be sure how far the transposable elements of nuclear organisms[5] are vestiges of the episomes of bacteria; but we cannot doubt that the circular DNA of bacterial chromosomes corresponds to that of the organellae, the mitochondria[6,7] and plastids,[8] found in later evolution. In the origin of nuclear organisms, it thus seems that the ancestors of the nucleus and of the organellae have entered into symbiosis by infection. As I have argued, infection has become heredity[9]. If this is so, it follows that two stages of chromosome evolution now co-exist in the cells of all nuclear organisms. They also collaborate by rules that are not yet understood. It also follows that this origin has been telescoped with all the other successive and decisive steps in nuclear history, namely the invention of mitosis, meiosis and the alternation of haploid and diploid sexual generations.

Finally, the sequences of nucleotides forming units of activity in the bacterial chromosomes are the first in a hierarchy of other units of activity. For they determine the structure of transfer and messenger RNAs which in turn determine the arrangements of

0028-0836/78/0276—0447$01.00

amino acids in the structures of proteins[10]. Some of these proteins are immensely durable in evolution. The foundations of chlorophyll, cytochrome C and haemoglobin[11], had evidently been laid in the pre-nuclear stage and their genealogy can be traced through the great groups of plants and animals whose development they underwrote Bacteria already had the machine tools with which the advanced industry of the cell was to be furnished[12].

Nucleus and chromosomes

The chromosome we were for long asked to take as our model was a cylindrical rod seen in fixed and stained cells at one stage of mitosis. Its motionless uniformity utterly contradicted the present and past functions that it was claimed to possess. Observation and experiment have gradually removed this contradiction. The bodies so neatly packaged at metaphase, conceal structures and activities and levels of organisation which we can now usefully survey.

The first example of structure and activity being connected was the 'spindle attachment' or centromere, a body responsible for the movements of each chromosome in cell division. Its functions were too big, too vital or too lethal, to be recognised in a breeding experiment. Yet it turns out to be a gene, one with a repetitive nucleotide structure such that, when broken by misdivision, its functions remain in its parts. The same is true of the nucleolar organiser which assembles RNA and proteins in the resting nucleus[13].

These two structures and activities are immediately necessary for the survival, the one of the chromosome, the other of the nucleus. But both appear in the metaphase chromosome modestly disguised as constrictions. More completely disguised is the differentiation seen in the prophase of meiosis, in the lampbrush chromosomes and in the polytene gland cells of flies. In those cells, the chromomeres, beads on a string, corresponding with the linear arrangement of genes, can be shown to have specific activities in protein production[14]. These activities vary between individual organisms and in the course of development. But they leave no trace in the metaphase uniformity of the living or conventionally fixed chromosome. To get inside the metaphase chromosome we have to use special methods and we then find a special kind of differentiation, not in beads but in blocks or segments.

The first step in tracing a differentiation of chromosomes in blocks was made by Heitz when he claimed that the property of failure to uncoil in the resting nucleus was specific and unconditional in certain segments of chromosome in plants and animals generally. To these segments which he argued were inert he gave the name of heterochromatin in contrast to the bulk of active euchromatin[15]. The second step was to make this resting stage differentiation visible at metaphase. In species of the wood-lily *Trillium* a period of freezing led to the appearance, at metaphase and anaphase of mitosis, of constricted segments. These segments were said to be starved of nucleic acid although the starvation, it now appears, was not of DNA but of the protein and RNA attached to it Similarly at mitosis and meiosis in newts of the genus *Triton*. Soon many genera of plants revealed their starved segments and in doing so showed variation on a scale not previously suspected. Often there was so much variation in the species and consequent heterozygosity in the individual that every plant examined could be distinguished by its own chromosome pattern or map[16].

The effect of starvation was to impair or modify the activity of H-segments (as they became known) in their three main mitotic aspects, reproduction in the resting stage, spiralisation in prophase and division or splitting in anaphase[17,18]. These associated effects were attributed to *allocycly*: the synthesis of heterochromatin DNA at a different phase of the mitotic cycle from that of euchromatin DNA[19]. This supposition was later confirmed by autoradiography[20]. Later an unspiralised H-segment was revealed in the X chromosome of a mammal, the male hamster *Cricetus aureus*, by true starvation[21]. Also H-segments in the bean *Vicia* were shown to be specifically broken by a particular reagent, maleic hydrazide, which presumably interferes with their reproduction[22,23].

A further step in exposing the block-differentiation of chromosomes was made when Caspersson in 1968, again using *Trillium*, found that an acridine derivative, quinacrine, would mark H-segments by differential fluorescence, either enhanced with AT bias or reduced with GC bias[24]. Temperature treatment could now be bypassed and the way was open to use digestion and denaturation before staining as a means of distinguishing the proteins organised by particular H-segments in the metaphase chromosomes. At last in warm-blooded mammals and man, as we had seen long before in plants, individual chromosomes could be recognised and their genetic history traced[25].

These various methods revealed evolutionary contrasts. The first was between the whole complements of species. Within the best known plant genera *Allium*, *Trillium*, and *Fritillaria*, for example, heterochromatin may vary in amount from a trace to a third of the whole complement. Such a wide range suggests a directional trend in evolution in which the chromosome has cut loose from the needs of the organism or its environment[26,27]. The second is between individual chromosomes. For some chromosomes (even X and Y in primates) prove to be unstable within a species or a race while others are stable over whole orders and classes[28].

These discoveries answer some evolutionary questions. But they raise new ones. How far does block or banded differentiation correspond with gene or chromomere structure? Clearly they represent the different needs of chromosome organisation at different stages in the cycle of the cell and of the organism[29–31]. How different these needs are is shown by the conditional behaviour of some heterochromatin. It may vary in relation to stage of development, position in relation to the centromere, haploidy or diploidy or even the action of an adjoining gene[32]. The most striking example of the last two appears in the X chromosomes of man and the mammals; notably in the mosaic coat pattern of the female tortoiseshell cat.

It seems that there is a hierarchy of control mediated in cellular organisms as in bacteria by enzymic messengers operating at many levels between the nucleotide and the whole cell and often canalised along chromosomes[33]. This hierarchy will have to be separately deciphered in many groups of plants and animals. But it already tells us that there is a division of function and hence an opposition of interest in the chromosome between its own needs and those of the cell and the organism. Most significant in the long term are the effects of this division on behaviour at meiosis.

The evolution of the sexual cycle

A sexual cycle of alternate conjugation and meiosis is characteristic of every group of nuclear organisms. Ninety years ago (just when the word chromosome was coming into use) Weismann suggested that this alternation was itself responsible for evolution: it secured a recombination of hereditary differences which would expose the variation of organisms to natural selection[34]. Two kinds of breeding experiment have in the intervening years turned Weismann's speculation into the main instrument of evolutionary thinking.

On the one hand experiments with organisms have shown that conjugation is the means of bringing differences together. And on the other hand experiments with chromosomes have shown that meiosis is the means of pulling them apart. Further both of the two complementary processes have proved to be under genetic control. But beneath this control a third variable is crucial: the time sequence of fertilisation and meiosis which we call the sexual cycle. These three variables are inevitably connected in evolution.

The sexual cycle evidently began in evolution with meiosis coming straight after conjugation as though no diploid mitosis were possible. This haploid supremacy is seen only in the

Protista and lower plants. From it animals seem to have moved abruptly into the opposite state of a complete diploidy; so abruptly that if they stood alone this revolution might have left us nonplussed. But a gamut of transitional stages is preserved in plants. In them meiosis is deferred by a series of steps, which have proved effectively irreversible. In this way the diploid phase has displaced the haploid, finally in a few Protista or Algae even extinguishing it (Fig. 1)[1].

In multicellular organisms, it has long been supposed that the diploid phase has expanded owing to the evolutionary advantage of its enlargement of the range of variation. The difference in its expansion between animals and plants we can now see is due to the different requirements of our second variable, the control of fertilisation, or the restraint of both outbreeding and inbreeding. In animals this control lies almost entirely in the mobile behaviour of diploid organisms. In plants it lies in the protein reactions governing incompatibility in their haploid and diploid phases. These reactions are now thought to have a genetic continuity all the way from their bacterial origins[35]. In the Angiosperms the haploid phase is preserved because in addition it is manifestly indispensible for the mechanisms of the style and of double fertilisation which provide the most exact and versatile of all genetic controls of the breeding system and the one which was evidently responsible for the origin of the angiosperms[36].

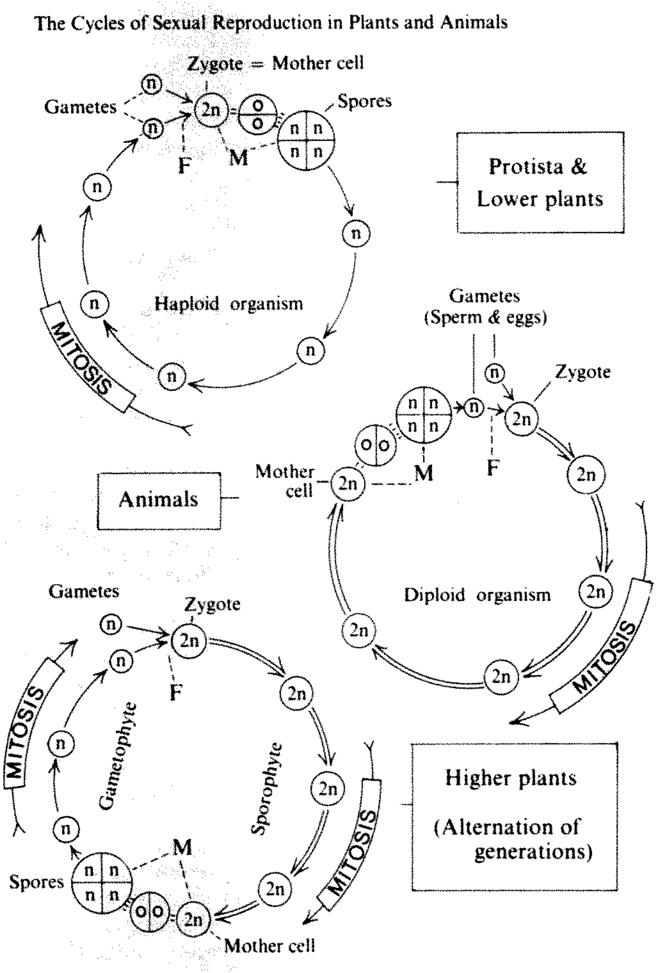

Fig. 1 Diagram showing the three types of sexual cycle found in nuclear organisms to illustrate their evolutionary connections. F, fertilisation or conjugation; M, meiosis; n and 2n, single and double lines, haploid and diploid.

Such is the macro-evolutionary panorama. Behind it however the breeding of organisms and of chromosomes now reveals an array of smaller events, the surviving successes of repeated evolutionary experiments. All of them concern genetic recombination as we can tell when either of the components of sexual reproduction, conjugation or meiosis, fails.

Characteristically in parthenogenetic plants and animals the two processes are suppressed together[37]. But without suppressing either, in hermaphrodite plants a mutation to self-fertility can quickly bring recombination to a standstill. In either case variation ceases. The stock is fixed as a stable race or species, adapted perhaps but no longer adaptable. So long as sexual reproduction continues without inbreeding, however, the option is left open and adaptability is preserved for the future.

Naturally, except in domestication[38], plants and animals as a whole have kept the option open. They are adapted to preserve the future interests of the species. These embrace the need to maintain, in changing environments and in successive generations of organisms, the cooperation of chromosomes and nuclei, mitochondria and plastids, genetic materials and agents, whose relations, as we saw, are relics of the past. When we recall that failure at any point may lead to sterility, a full stop, we understand why this problem of internal adaptation, of mutual selection, baffled Darwin and was avoided by the Darwinians.

The adaptation of meiosis

To understand the taking apart of the differences brought together in the sexual cycle we must take note of the inherent paradoxes of meiosis. For meiosis connects individuals and generations; it also separates them. At meiosis the DNA code is organising both an unlimited continuity of organisms and a repeated discontinuity between them. And in meiosis the chromosomes make themselves the agents of a drastic choice between stability and variation. How do they do it? By a variety of devices modifying meiosis which arise, to use Wilson's phrase, as natural experiments[39]. For they appear in all animal and plant groups throughout evolution without regard to affinities or lineages or levels of organisation.

The most widespread of these devices springs from the earliest manifestation of sexual differentiation itself. In all kinds of organisms whether hermaphrodite or separate-sexed, in which small sperm fertilise large eggs, these germ cells are produced by way of two sizes of cell and hence by way of two forms of meiosis. In its common origin before sexual differentiation this meiosis must have uniformly required pairing, crossing over and chiasmata between parental chromosomes[1]. But one of the two forms, male or female, later often found another way of doing it. Reduction, segregation and recombination were achieved without crossing over, or the formation of chiasmata, or the separation of genes within the chromosome. Thus in one sex, always the XY sex where there was one, never of course in both sexes, whole chromosomes were inherited as a unit[40].

In this way two tracks had been laid in heredity. On one track new chromosomes are constructed by crossing over in every generation. On the other, old chromosomes are kept intact potentially forever. This elegant device was the key to the controlled breeding of *Drosophila* in experiments. But for some time before it had been the key to the breeding of flies in nature and their evolution[41].

The two-track system works in a variety of ways. Meiosis without chiasmata is the simplest. It is found not only in flies but also in mantids and scorpions, moths and mites as well as in certain hermaphrodite plants[42,43]. Haploidy in the male sex is another way of reaching the same goal. It allows bees, wasps and ants, and single species of beetles and bugs, to avoid all recombination in the male sex[13]. But it has one drawback, that these males have no offspring of their own sex. Most widespread of two-track systems is probably that in hermaphrodite plants and in some Amphibia where the large chromosomes allow us to see the frequency and distribution of chiasmata sharply or slightly contrasted between the two sexes[41,44].

The mechanisms of two-track heredity are thus slight or drastic, direct or devious. In them heterochromatin and accessory chromosomes sometimes play a part whose working remains to be explored. But in its consequences (which are its evolutionary causes) two-track heredity is sharply definable. So long as outbreeding is maintained, the choice of track gives the sexual process an unforeseen, and hitherto unrecognised, scope and power. For not only does it generate diversity through the uncertainty it organises in recombination. It also organises its distribution selectively in succeeding generations.

On this basis we can look again at the evolution of sexual reproduction as a whole. Its origin and all its adaptations now show us that it concerns not the organisms in which they began but the selection and survival of their descendants. Never are they concerned with adaptation to any present environment; always either to future environments or to future internal arrangements in the species, sometimes in long hierarchical successions as in, longest of all, the evolution of the life cycle itself.

What has made this possible is the continuity of the chromosomes from generation to generation. Their continuity (or immortality, to use Weismann's term) overrides the discontinuity or individuality of organisms which has over-awed our naturalists: embryologists and paleontologists, Darwinians and Mendelians alike, have taken it as the axiom of axioms. But it is the continuity of the chromosomes which has allowed genetic systems to be built on natural experiments; these experiments have been tested on individuals, but they have been maintained by communities which like the chromosomes are extended in time and space beyond the individual, beyond the organism.

Direction and feedback in selection

Comparisons of organisms in both their living and fossil anatomy have long convinced us that they often show great trends in the evolution of their bodily structure. These trends were first given the name of *orthogenesis* by paleontologists who saw a convenient Lamarckian interpretation for them[45]. They are, however, easily understood as the product of positive feedback in natural selection where one change favours rather than disfavours another in the same direction. If this is so we have to ask whether such trends occur at the other levels of evolutionary change which we now recognise, and with what effect.

In fact we find trends at all our lower levels of evolutionary change. Examples are: repetitive sequences in DNA[46,47]; extreme proliferations of heterochromatin[48], multiplication of chromosomes by polyploidy in plants[38]; by fragmentation in both plants and animals (giving bimodality of chromosome size in many groups)[38,43]; multiplication of accessory and X chromosomes[49–52]; decay of the Y chromosomes[39,49]; expansion of interchange hybridity giving ring formation at meiosis[38,40]; and extravagant incompatibility allelism in plants[35].

With this variety of examples we can now ask another question, whether any connection exists between trends at different levels. The answer is that no such connection seems to exist. A change at one level may no doubt be responsible for initiating a trend at another level, but no more.

Take the polyploidy that is seen in flowering plants. It sometimes leads to a series of multiples: 4, 8, 16, 32 and so on. The scale and range of this occurrence in thousands of genera, is now so well known as to constitute a vast natural experiment[38]. Now polyploid plants arising in cultivation are enlarged in size and plant breeders welcome this gigantism. But in nature the plants themselves do not. On the contrary they either reject it or correct it. Even, we may say, when they reduce their chromosome size, they actively disconnect it from their bodily structure[13].

What then do the polyploid trends achieve?

Evidently each jump has separated a new stock from an old one. By inter-sterility it has initiated a new species isolated genetically from its parent[53]. The same is true in less degree of all changes of chromosome number in both plants and animals. But it is also true that these changes are commoner where the organism is small and short-lived so that the species can afford to experiment; they are less common where the organism is large and its slow propagation makes the gamble more costly. Notably is this so in the flowering plants and in our own group, the primates[54].

Interchanges between chromosomes demonstrate the same principle. How do they establish themselves? In all outbreeding plants and animals migrating colonies are liable to be isolated and so compelled to inbreed. In this emergency parthenogenesis is one means of preserving the reservoir of variation and hybridity they may need for survival. Polyploidy is another. A third is interchange[38,55]. Two chromosomes AB and CD exchange segments to give BC and DA. The nucleus is then hybrid and the chromosomes, old and new, can no longer simply pair. At meiosis they form a ring of four: AB-BC-CD-DA. Such a ring can give viable gametes only of two types, the old and the new, AB, CD and BC, DA. Either of these uniting with a similar partner will give a complete homozygote with impaired viability. But by uniting with the other type it will keep the full heterozygosity of its parent. The interchange hybrid with its ring of four therefore both grows well and breeds true. Further interchanges can enlarge the ring to six, eight and on to fourteen. Each step in this trend feeds back to make another step in the same direction more desirable. Finally all the variation available in the outbred community will be trapped and held in one inbred and now true-breeding hybrid stock or species.

Thus the effect of interchange is to raise barriers to recombination not through crossing but through crossing over, not at the diploid but at the haploid level, and not between organisms but between chromosomes.

The classical instances of this process are the species of *Oenothera* which have been forced into their evolutionary trend by a conversion from outbreeding to inbreeding, itself promoted by migration across North America after the retreat of the ice. De Vries founded his mutation theory on the breeding behaviour of these species and we can now at last do justice to his much-disputed argument[56]. The building up of his hybrid species clearly depended on connecting the two primary initiatives, of genic self-compatibility and chromosome interchange. Both of these were internal or genetic changes. Both we may call mutations. But it was through the breaking down of these hybrid species, their secondary evolution through hybridisation in Europe, that de Vries came on what he called mutations[13].

Oenothera thus shows us both the building up and the breaking down of species. And in both processes we are left agreeing with de Vries that the selection of organisms by adaptation to the environment is secondary to the internal, lower level, processes of mutation. At the same time we discover that the trend in building up interchanges has no connection with any trend in the bodily evolution of the organisms, the plants[38].

Most notable for their evolutionary trends are the sex chromosomes in their XX–XY systems of determination. Both X and Y have two parts, a pairing segment in which the two exchange by crossing over, and a differential segment without crossing over and hence, for the Y, confined to one sex[40]. This restriction as we might expect makes the Y especially vulnerable and its evolutionary disappearance has been independently inferred in most large animal groups[42,43]. Organisms in which the loss has occurred do not however exploit it. On the contrary we again have to say that they correct it. They accept interchange of X or Y with a pair of autosomes. In doing so they often initiate a trend. They build up a ring or chain of chromosomes at meiosis in the heterozygous sex. This process reaches a climax in a number of plant and animals: 3 chromosomes joined in a marsupial[57] 5 chromosomes in a hop[13] 8 in a mistletoe[58] 9 in a centipede,[59] 14 in a termite,[60] 9 or 10 in each of those remarkable relics, the monotreme mammals[61].

In these examples the heterozygous sex extends its fixed hybridity while allowing the homozygous sex to continue its free recombination. Two advantages have thus been combined and reconciled in one sytem: the true-breeding hybridity of *Oenothera* and the two-track heredity of *Drosophila*.

If we look at instability in general at different levels this conclusion is strengthened. Evolutionary similarities of many kinds can now be compared. Organisms provide us with our conventional and systematic standards. The chromosomes show a variety of evolutionary trends. Proteins such as isozymes[62] or haemoglobins[63], and sequences of DNA show much greater stability. But if we look at each group separately we find that each has its own character. As between man and the apes it is the brain that has changed most, the blood and the DNA least, and the chromosomes lie between[47].

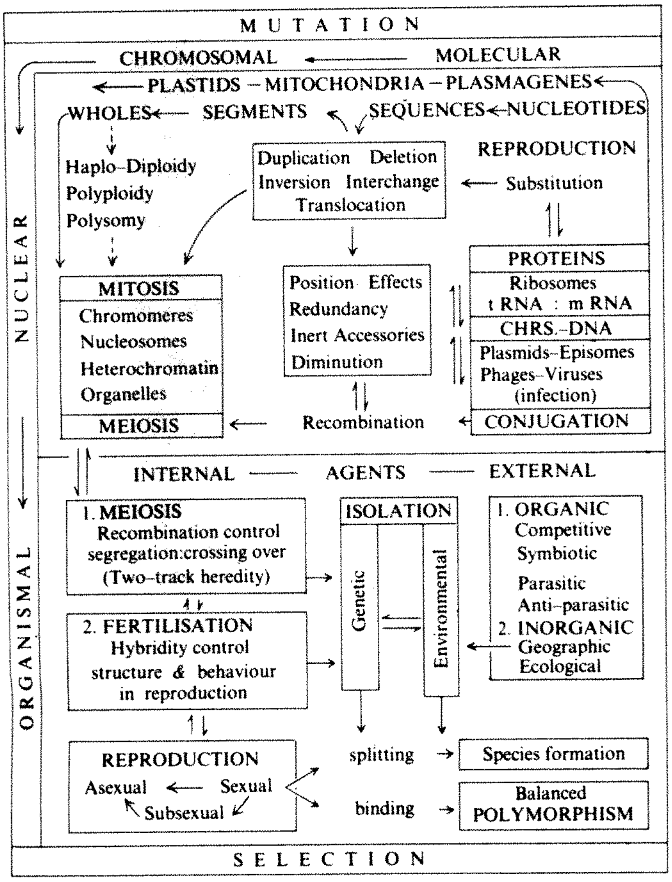

Fig. 2 Diagram showing the multilateral evolutionary relations of molecules, chromosomes, organisms and species subject to mutation at lower levels and selection at all levels.

Although DNA, genes and chromosomes, organisms and species are connected in activity they are separated in selection. It is as though they were protected from one another in stability. We do not know how this happens. But it is utterly clear that if trends at the molecular and chromosome levels are demonstrating feedback in selection so also are trends in the giraffe's neck or the vertebrate's brain. And the Darwinians after all need not have been embarrassed by the notion of orthogenesis[45,64].

The origin of species

The evolution theory began with organisms. For Darwin (in the first and in the last edition of the *Origin*) natural selection worked 'solely by and for the good of each being', that is of each organism[65]. And, if it worked on heredity, that heredity was a property of the organism. In the same vein Morgan wrote that 'the chromosomes fulfill the requirements of genetics' meaning that groups of genes do what organisms require them to do[66,67]. Which is true if we allow that the experimenter is seeing nature back to front.

Again when Darwin wrote that species 'originated' as varieties he meant that they arose from differences between organisms. Haldane therefore, putting Morgan's genes into Darwin's organisms, might claim that differences between varieties were 'generally due to a few genes with relatively large effects' while the chromosomes were sometimes convenient in assembling the genes to make still larger differences between species. In principle the mutation of genes, the spatial isolation of organisms, and the natural selection of one through the other, made varieties into species. If the details might be left in the dark, these were the 'causes of evolution'[64] (see Fig. 2).

At this point, however, a number of details were being brought into the light. Differences between related species sometimes seem to have no adaptive connection with their external environments. Might not sampling errors in mendelian assortment be responsible? In small populations, Sewall Wright suggested, these errors would checker the smooth working of natural selection[68,69]. Slowly we have come to see the scope of this principle. But the sampling we notice concerns not just the organisms and genes of Wright or Haldane but the whole gamut of variation from the nucleotide to the species itself. It is indeed a hierarchy with many interactions which we need to examine.

Every new polyploid begins as the smallest of all populations, a unique individual. And it is cut off from its parental diploid stock, often for ever. It is therefore at once a potential new species. In a different way every new inversion within a chromosome is a unique individual. As a heterozygote it is prevented from crossing over with its sister segment, often for ever. Every new interchange likewise yields a unique individual. All of these establish, by an act of sampling, new populations of chromosomes, and nuclei and organisms. And even when the changed chromosomes lie together with their alternatives in the same cells they are genetically isolated from one another[53,70]. For, in their possibilities of recombination, they might as well be ages or oceans apart.

Here *Oenothera* illustrates both the rule and its exceptions. For, in the hybrid species, the genetic isolation of gametic alternatives is not always for ever. It may break down, by crossing over. It then gives mutations; but, unlike the new mutations of *Drosophila*, they are not always deleterious since they are due to combinations of chromosomes already tried out by selection.

We can now see that all outbreeding species are fields of genetic recombination; that any blocking of recombination splits the species; and its source may be, indeed must be, either external or internal, either environmental or genetic. Further we can sometimes see which it is; but not always, since either may quickly promote the other. We can however see from our experiences of chromosomes that when the initiative is external the populations separated will contain more genetic differences than the naturalist would imagine. But not all such differences will contribute to the splitting of a species. Throughout plants and animals the variation within a species is partly concerned with the opposite task, the long-continuing task of holding the species together.

This principle is true at all our levels of analysis and it is best described in terms of the balanced polymorphisms of Ford. Blood groups, immunity reactions, and mimicry systems in animals and the incompatibility alleles of plants all serve to bind a species together[71]. Our knowledge of heterochromatin bridges the gap between these systems and the sex chromosomes of plants and animals. In the heterozygous sex these in turn may be linked with inversions as well as interchanges. An example is the 'sex-ratio' super-gene in *Drosophila*. The males that carry this floating recessive complex correct the sex-ratio of the population by having an abnormal meiosis which gives largely female progeny. The complex is based on inversions, three of them overlapping, and it is common to a group of many species. It is not as old as the X chromosome but it is clearly older than all the species together that carry it[72].

Consider now the entire range of variation arising in a species at all material levels from the nucleotide to the nucleus. It is evidently available to the species for two kinds of selection and adaptation. These are variously developed and compete with one another. On the one hand, older variations are largely pre-empted as polymorphisms which serve to bind the species together. On the other hand, newer variations are always becoming available which may serve to split it apart. But when this split succeeds it still largely fails to break the continuity of the older polymorphisms.

The competition between these choices means that we have to explore the balance between the present needs of the individual and the future needs of the species, between the internal and the external opportunities of each community. Sometimes as with the origin of the Angiosperms the incompatibility super-gene may have both splitting and binding functions open to it[73]. And sometimes, as in the beginning of man, a mutational initiative in a single cell, by the union of two chromosomes to make one, may decide the origin of a new species or new family[54]. In Fisher's hands natural selection might have seemed to be a truism[74] but these choices and conflicts that are now open to our examination have nothing of the truism about them.

The use of a diagram

Darwinians have seen evolution as the product of mutation and selection. We may agree. But for them mutation, the primary process, acted at the lowest level in their scheme, which came to be known as the 'gene'. And selection, the secondary process, acted, at the highest level in this scheme, that of the organism. For us the physical continuity exists, and the mutation and selection therefore act, at many levels. For us mutation runs all the way from the single nucleotide to the nucleus and the plasmagene. And selection runs all the way from the tri-nucleotide to the community of organisms and, what is more, through a succession of generations. Selection is therefore enormously extended in time and in space.

To use this knowledge we need to take to pieces and reassemble both the assumptions and the conclusions that our predecessors, properly in their time, attempted to establish. We need to think of the relations between levels and systems and in order to do so we need a new framework, a new diagram. Even in its two dimensions such a diagram may help us to see both the connections and the gaps in our understanding.

What we see is heredity changing and using its materials and its processes, derived from the past, to meet the needs of the present and the hazards of the future. It does not show us how often, as in human affairs, the long-term advantage is set aside in favour of short-term opportunity. But it allows us to see how very long the past is both for molecules and for chromosomes. And above all it allows us to see that behind the mendelian choice between change and no-change lie a succession of deeper alternatives within heredity itself: between control by the nucleus and by the cytoplasm; between the fixing or recombining of nucleotides, of genes, of segments and of chromosomes; and between the binding or splitting of sexes, of races and of species.

In all these choices mutations are the basis of future adaptations and evolution. They are pre-adaptations not just one stage but a lengthening succession of stages in advance of the transformations that overtake organisms and communities. Each of the great steps in this process, beginning with RNA and DNA, L-amino acids and proteins, has in turn prescribed some future developments and proscribed others. All have curtailed darwinian randomness. Among the greatest steps of all, some were telescoped in the invention of the nucleus and the nuclear chromosome, mitosis and meiosis; others were fully exposed in the evolving sexual cycles.

When, in 1871, Matthew Arnold suggested that Darwin's ideas were 'all in Lucretius' in one respect he understated the case[75]. To atomists, old and new, changes of atoms were bound from the beginning to have that priority over selection of which Darwin was uncertain[76,77]. And it was only in the last stages of evolution, and only to us today, that the consequences of this priority became unmistakably clear. For the little changes which came near the end gave that genetic control of fertilisation, and through gestation of development, to which first the Angiosperms and then the mammals owed their origins[36,37].

In these processes the forward-looking or experimental capacity of selection culminated. For they allowed heredity to control the environment not only of each organism but also of the following generation. What was in neither Lucretius nor Darwin was the extension of this principle which has been demonstrated by the history of man himself, the extension which allowed individuals to create the environments of indefinitely succeeding generations. Whence sprang a process of directed evolution with a feedback so formidable that it is only now brought within reach of our enquiry[54].

Eternity is unstable

Frank J. Tipler
Department of Mathematics, University of California, Berkeley, California 94720

We show that if the Universe expands forever, it will become increasingly irregular in the far future. In particular, we demonstrate that the Hawking black hole evaporation process causes a vortical instability to develop in spatially homogeneous spacetimes which are approximately $k=0$ Friedmann universes. We associate the increase of irregularity with the increase of gravitational field entropy, and thus provide a novel picture of the universal heat death.

THE aim of this article is to describe, in the light of recent developments in gravitation physics, the likely future state of the Universe if it expands forever. We shall be especially concerned with extending the analysis of Collins and Hawking (CH), who in their classic paper[1] studied the asymptotic stability of the ever-expanding Friedmann universes under the action of generic, homogeneous perturbations. Their aim was to test the plausibility of Misner's idea that our Universe, now virtually isotropic, could have arisen from an arbitrarily non-uniform set of initial conditions[2,3]; its present regularity being guaranteed solely by the laws of physics with no memory of initial conditions. They examined the most general spectrum of homogeneous perturbations to the flat, ($k=0$), and open ($k=-1$), Friedmann models, and concluded that unless the Universe were neighbouring the special state of zero total energy ($k=0$), the property of isotropy is unstable. Only initial data of zero measure in the metaspace of all possible cosmological Cauchy data give rise to universes of zero total energy which are able to isotropize in the future. In general, the open universes with non-zero total energy will become increasingly anisotropic with the passage of time[4,5]. The Collins–Hawking analysis tells us that either the Universe is young—instabilities having had insufficient time to grow remarkably as yet—or that the Universe is in a highly preferred, zero measure, binding-energy state. They opt for the second alternative by invocation of the anthropic cosmological principle[6–8], which we discuss below.

By extension of the CH theory we shall show that there are novel consequences for the future dynamics and thermodynamics introduced by particle evaporation from black holes[9,10]. It transpires that the non-conservation of baryon number of the gravitational interaction [11] creates an inevitable radiation-filled environment in the far future of a universe which approximates the zero energy Friedmann model. This thermodynamic state renders such universes unstable to the development of vorticity and random peculiar velocities. These universes can no longer isotropise in the manner defined by Collins and Hawking; they become increasingly dominated by the centrifugal and kinetic energy of material motions rather than the particle rest energies and tend towards a dynamical state thay may be viewed as radiation-dominated, relativistic vortex. Thus, the Collins–Hawking proof of the instability of the $k=-1$ Friedmann universe coupled with our proof of the instability of the $k=0$ Friedmann universe shows that all ever-expanding universes are unstable: they do not isotropise at large times.

In the following sections, we first give a short history of the studies dealing with the final state, and then we describe the possible and probable outlines for the classical and quantum evolution of the Universe into the far future. The consequences of this discussion for the stability of Friedmann universes are calculated and some further general ideas regarding the asymptotic behaviour of the Universe ventured in the final section.

The past

Eschatological studies of the Universe have periodically attracted the interest of many physicists, philosophers and astronomers[12,13]. These investigations have, in the main, been precipitated by the second law of thermodynamics which arose as a generalisation of Carnot's work[14] in 1824 on the efficiency of heat engines. In 1852 Lord Kelvin extended Carnot's work and propounded[15] the "universal tendency in nature to the dissipation of mechanical energy". Two years later, Helmholz made the first explicit statement of the now familiar notion of the 'heat death of Universe'. He envisioned an ultimately stable state of all-encompassing thermodynamic equilibrium[16]: "the Universe from that time forward would be condemned to a state of eternal rest". Clausius echoed Helmholz' ideas as follows[17,18]

> "the more the Universe approaches the limiting condition in which the entropy is a maximum, the more do the occasions of further changes diminish; and supposing this condition to be at last completely obtained, no further change could evermore take place, and the Universe would be in a state of unchanging death."

These ideas were widely discussed in the latter half of the nineteenth century and indeed had a profound influence on the *Weltenschauung* of that period[19,20]. Jeans[21] and Eddington[22] were responsible for bringing the notion of the 'heat death' into relativistic cosmology. Eddington asserted in 1931 that[23]

> "It used to be thought that in the end all the matter of the Universe would collect into one rather dense ball at uniform temperature; but the doctrine of spherical space, and more especially the recent results as to the expansion of the Universe, have changed that.... It is widely thought that matter slowly changes into radiation. If so, it would seem that the Universe will ultimately become a ball of radiation growing ever larger, the radiation becoming thinner and passing into longer and longer wavelengths. About every 1,500 million years it will double its radius, and its size will go on expanding in this way in geometrical progression for ever."

Eddington's view of the Heat Death has important similarities with the picture of the Heat Death derived in what follows.

The classical future

Let us first consider the ultimate fate of the large aggregates of matter that populate the present day Universe. As time passes, clusters, galaxies and other stellar systems will become increasingly bound by gravitational forces since they will radiate away their binding energy in the form of gravitational waves. Dead stars with mass exceeding the Landau–Chandrasekhar limit, $M_{\rm LC} \sim \hbar^{3/2} m_{\rm n}^{-2} \sim 1.5\, M_\odot$ will be the first objects to become black holes, but galaxies and the largest bound configurations $\sim 10^{17}\, M_\odot$ will also eventually follow them. The time taken for the radiation of the binding energy to precipitate clusters into black holes may be roughly determined from the time scale on which these structures will change their quadrapole moments. Equating the gravitational energy[24] $\sim M^2 R^{-1}$ with the rotational energy we obtain from the Landau–Lifshitz radiation formula[25,26] a lifetime $t_{\rm g} \sim G^{-3} c^5 R^4 M^{-3}$ seconds against gravitational wave decay.

The time scale for a large $10^{15}\, M_\odot$ cluster to evolve into a black hole state under the assumptions of these naive arguments is $\sim 10^{19}$ yr.

This radiative loss of binding energy is the principal means whereby the largest aggregates of matter will become increasingly bound into trapped, black hole states. Another is by the 'evaporation' from their interiors of objects which gain sufficient kinetic energy from gravitational deflections, encounters and instabilities to attain escape velocity. Such 'evaporation' will clearly accelerate the central core's collapse to a compact state since objects with positive energy will be diffusively ejected from the system leaving its total energy thus more negative. The details of such mechanisms are exceedingly complex because of subtle collective relaxation effects[27], but the time scale will clearly be related to the relaxation time for gravitational encounters[27–30].

Clusters will for example evaporate galaxy-sized objects in $\sim 10^{11}$ yr and stellar-size ones in $\sim 10^{23}$ yr. Of course, many of the assumptions used to generate these numbers have been stretched to the limit (and beyond) in this context; it serves merely to illustrate that evaporative effects will occur to augment the radiative decay of self-gravitating systems.

Material may be cycled through infall and evaporation many times as the Universe moves inexorably towards a state consisting of supermassive black holes, debris in the form of 'dead' matter, elementary particles, and radiation. The fate of these components will ultimately be determined by quantum processes and we now turn to consider them.

The quantum future

The preceding section traced the evolution of an ever-expanding universe until its matter resided in essentially four basic states: (1) black holes; (2) condensed objects such as neutron stars, black dwarfs, and various clumps of matter; (3) dispersed elementary particles; (4) radiation. However, the evolution of the matter will not stop here. In fact, we wish to argue that material in the first two states will eventually be converted via quantum processes into the third and the fourth types, and that those open universes now neighbouring a $k = 0$ Friedmann universe will eventually become radiation dominated.

Condensed objects of type (2) will be converted into either black holes or dispersed elementary particles by quantum tunneling processes. The zero-point motions of the particles comprising a neutron star or black dwarf could cause the surface of the star to fluctuate inside its Schwarzschild radius[31], or else impart escape velocity to a particle on the stellar surface. If the former does not occur, then the latter process will eventually lead to the complete evaporation of the star: its particles will become completely dispersed[32]. As an example of this dispersal process, consider the decay of a heavy nucleus. Its constituent particles can tunnel through the potential barrier as long as the total mass-energy of the escaping particles is balanced by an increase of nuclear binding-energy, and this will be the case until the nucleus has decayed into ^{56}Fe. As no nucleus has a greater binding energy than ^{56}Fe, further decay can proceed only after nuclear baryons decay, and the decay will be caused by the Hawking process discussed below. The decay of a black dwarf is similar. It will first decay into an iron star, then a neutron star, and then either tunnel into a black hole, or evaporate as its constituent baryons decay.

Hawking has shown[10] that a black hole will emit black body radiation at a temperature which is inversely proportional to its mass. A black hole thus cannot be a final state of matter. Instead, most of a black hole's mass will eventually be turned into radiation, and a small fraction into high-velocity elementary particles. (Copious particle production will not occur until the final stages of the black hole evaporation when the black hole temperature reaches 10^8 degrees, see ref. 33). A black hole will not begin to radiate away its mass until the expansion of the Universe cools the ambient radiation below the black hole surface temperature, but in an ever-expanding Universe, this will inevitably happen. To see this inevitability, note that there are two effects which act to augment the mass of a black hole: the accretion of matter and radiation by a black hole, and the coalescence of black holes into larger ones. The complete evaporation of black holes will occur if the ambient radiation temperature, which is proportional to $1/R$, is in the long run being reduced faster than the two above mentioned effects can reduce the temperature of black holes, which is proportional to $1/M$. Carr[34] has shown that for black holes which are initially smaller than the particle horizon, accretion by matter and radiation in an environment where the average matter density is proportional to the cosmological density cannot increase the black hole mass by more than an order of magnitude in the entire future history of the Universe. At late times, the matter density near a black hole should be proportional to the cosmological density. Furthermore, no black hole whose event horizon does not intersect the initial singularity (that is, non-*ab initio* black holes) can be larger than the particle horizon (this fact can be seen by inspection of the appropriate Penrose diagram). Thus if we make the physically reasonable assumption that there are no *ab initio* black holes, we have a cutoff at high mass in the black hole mass distribution at any given time; the Carr argument then tells us that there is an upper bound to the mass of a black hole, and hence a non-zero lower bound to the black hole temperature, at all times. This assumes, of course, that the black holes cannot coalesce to form black holes of arbitrarily large mass. To calculate the increase of black hole mass due to coalescence, note that the rate of increase of mass due to black hole collisions is proportional to $\sigma_{\rm BH} \rho_{\rm BH} \langle v \rangle$, where $\sigma_{\rm BH}$ is the black hole capture cross-section (this factor includes the potential of the gravitational Coulomb effect to capture other black holes). $\rho_{\rm BH}$ is the black hole mass density, and $\langle v \rangle$ is the average velocity of the black holes with respect to the fundamental observers. Novikov and Thorne[35] have given $\sigma_{\rm BH} \propto M^2 \langle v \rangle^{-2}$, and so we have $\mathrm{d}M/\mathrm{d}t = \rho_{\rm BH} M^2 \langle v \rangle^{-1}$. Now $\rho_{\rm BH} \propto 1/R^3 = 1/t^2$. Assuming $\langle v \rangle \propto t^{-m}$ and integrating, we see that M is bounded above even in the limit as $t \to +\infty$ if $m < 1$, which will hold if $\langle v \rangle \propto 1/R$ or $1/R^{1/2}$. This means that the total number of collisions occuring in infinite time will be finite in the Friedmann universes considered. Thus in any ever-expanding Universe, black holes will eventually completely evaporate; in the far future of an open Universe, all matter will be reduced to elementary particles and radiation.

But the evolution of matter will not cease here. A careful consideration of the Hawking process leads to the conclusion that protons and electrons—supposedly stable elementary particles—are in fact unstable and will decay into massless particles. The 'no-hair' theorem[24] tells us that a black hole is characterised by only three parameters: mass, angular momentum, and electric charge. Hence, there is no way to distinguish between a black hole formed by the collapse of matter from a black hole formed by the collapse of anti-matter. The Hawking process causes an equal number of particles and anti-particles to evaporate from a black hole, so if a black hole which completely evaporates was originally formed of matter, the combined process of black hole formation and evaporation leads to a net decrease in the total baryon and lepton number in the universe. That is, the Hawking process can violate the conservation of baryon and lepton number. Since general relativity contains no intrinsic length scale, black holes of any size can in principle exist; this tells us that the gravitational interaction intrinsically violates lepton and baryon number. (One way of thinking of this is $p+e\rightarrow \mathrm{BH}\rightarrow 2\gamma$). That is, the proton and electron comprising a hydrogen atom can quantum-mechanically tunnel inside their combined Schwarzschild radius to form a black hole, which then decays via the Hawking process into two photons). Some decay modes of electrons and protons via this gravitational interaction are

$$\begin{aligned} p &\rightarrow e^{+}+\pi^{0} \\ p &\rightarrow e^{+}+2\gamma \\ p &\rightarrow e^{+}+\nu+\bar{\nu}. \end{aligned} \tag{1}$$

Protons and electrons are known to be stable within the limits of experimental measurement[36], so the time scale for the gravitational annihilation of baryons and leptons must be extremely long—a rough calculation by Zel'dovich[37,38] gives a half life t_0 of 10^{45} yr. This half life is very small when compared with eternity, however, and all baryons will eventually decay into leptons and radiation. The charged leptons themselves do not decay because the gravitational interaction conserves electric charge.

The baryon mass density will be proportional to $e^{-t/t_0}t^{-N}$ at late times, (at least until the reverse reactions of (1) become important. In the low temperature regime considered here, the reverse reactions will be dominated by the zero point fluctuations considered below) where the value of N depends on the effective equation of state ($N=2$ and $3/2$ for matter-dominated and radiation-dominated cosmologies respectively). The ambient radiation density is proportional to t^{-N}, so the radiation density will eventually dominate the baryon density. Neglecting for the moment the zero-point fluctuation, the material of the Universe at late times will essentially consist of an electron–positron plasma in a radiation bath. One might expect that the electron–positron pairs would rapidly annihilate leaving only radiation, but in an expanding universe, this does not necessarily hold. For a sufficiently rapid expansion, the electron–positron pairs may become the dominant form of matter. The mass density of the electron–positron pairs in a Friedmann universe is given by

$$\frac{\mathrm{d}\rho}{\mathrm{d}t}=\frac{-3\rho}{R}\frac{\mathrm{d}R}{\mathrm{d}t}-\sigma_{\mathrm{Thomson}}\langle v\rangle\rho^{2}-[\text{electrical attraction term}]$$

For all ever-expanding universes, the second term becomes much smaller than the other terms at very late times, (contrast the black hole coalescence effect discussed earlier). For $k=-1$ universes, or universes which approach this class of Friedmann universes in the infinite future limit, the first term dominates and the electron–positron mass density controls the expansion. However, for ever-expanding universes neighbouring a $k=0$ Friedmann universe, the electrical attraction term will cause the electron-positron mass density to decrease faster than the ambient radiation mass density, so that eventually the former can be neglected in comparison with the latter.

The physical mechanism for this is as follows. In $k=0$ Friedmann universes, the fundamental observers have zero gravitational binding energy. This means that electron–positron pairs will become electrically bound—and hence eventually annihilate—if $\frac{1}{2}m\langle v^{2}\rangle$ becomes smaller than the electrical potential energy of a pair (which is proportional to e^{2}/R), where $\langle v^{2}\rangle$ is the mean square velocity of an electron or positron with respect to the fundamental observers. Now $\langle v^{2}\rangle\propto 1/R^{2}$, and so the electrical potential energy of a pair will eventually become larger than the kinetic energy—an electron–positron pair will become bound. The time needed to annihilate will depend on the initial distance at which the particles first become bound, and so if the initial spectrum of velocities is either maxwellian or determined by the decay of protons via the Hawking process (the number density of protons being proportional to $e^{-t/t_0}t^{-N}$) the mass density of electron–positron pairs will decrease according to $t^{\beta}e^{-t/t_w}$, for some constants β, t_w. Note that this is not inconsistent with the fact discussed earlier whereby black holes undergo only a finite number of collisions in infinite time. It is only necessary that an electron–positron pair undergo one collision in its history for annihilation.

At very late times, then, the universe near the $k=0$ Friedmann will have material consisting of radiation, reactions such as (1) and their reverse, plus the reactions

$$\begin{aligned} e^{+}+e^{-} &\rightleftharpoons 2\gamma \\ e^{+}+e^{-} &\leftrightharpoons \nu+\bar{\nu} \end{aligned} \tag{2}$$

and the zero-point energy. If we include the zero-point contributions to (1) and (2) in the zero-point energy, we see that reactions (1) and (2) go from left to right—from matter to radiation—because the number of massless particles with energies sufficient to produce an electron-positron pair, say, is proportional to the Boltzmann factor $e^{-1/T}$, and $T\propto t^{-N}$, since the expansion is cooling the ambient radiation. The reaction from left to right, on the other hand, is proportional to the particle number density, which is decreasing according to t^{-N}. Thus at very late time the matter will primarily be radiation and zero-point energy.

The effective stress-energy tensor of the zero-point energy has been recently calculated by Davies *et al.*[4,5]. For example the vacuum energy density for massless fields in a flat background evolves as $\rho_{\mathrm{vac}}\sim t^{-4}$ and decays as $\rho_{\mathrm{vac}}\sim R^{-8}$ or $\sim R^{-6}$ in radiation and matter dominated universes respectively.

The calculation of a realistic zero-point energy equation of state would involve numerous interacting fields, and would be too difficult to carry out. However, it seems reasonable to assume that the zero-point energy of the interacting fields at very late times in an expanding universe would be that of those particles which would be final state particles in the absence of the zero-point energy. We have argued above that these particles would be massless particles of various types (photons, neutrinos, gravitons), and so the effective vacuum energy would be negligible compared with the radiation background at very late times. Thus a universe neighbouring a flat Friedmann universe will be dominated by radiation at late times.

The dynamical future

We shall summarise some of the assumptions and conclusions of Collins and Hawking and discuss certain other points of the general and technical interest in their calculation before seeing how they are significantly modified in the light of Hawking's subsequent[10] and remarkable discovery of the quantum mechanical evaporation of black holes and accompanying baryon non-conservation[11]. We have just argued that these processes will ensure that the asymptotic environment of the Universe will be that of a radiation gas in the marginally bound case.

Collins and Hawking were the first to attempt to frame a precise definition of isotropisation for a homogeneous cosmology; a model was said to isotropise if, as $t\rightarrow\infty$, it satisfies the following

I1: $V=R^{3}\rightarrow\infty$, where V is the co-moving volume.
I2: $T^{00}>0$ and $T^{0i}/T^{00}\sim v^{i}\rightarrow 0$, where $T^{\mu\nu}$ is the stress energy tensor; v, velocity field of the matter.
I3: $\sigma/\theta\rightarrow 0$, where σ is the kinematic shear and $\theta=\dot{V}/V$.
I4: $\beta\rightarrow\beta_0$, where $\beta=\int_0^t\sigma\,\mathrm{d}t$ and $\dot{\beta}_0=0$.

Condition I1 aims to exclude closed universes (those having compact, spatial three-slices of homogeneity). Another criterion must be used in homogeneous models that recollapse; one proposal[39] gauges the isotropisation by measuring the degree of isotropy in the spatial three-curvature at maximum volume. Condition I2 of the Collins–Hawking criteria requires the peculiar velocity of matter motion relative to the surfaces of homogeneity to die away in time, whilst conditions I3 and I4 seek to exclude those models in which the shear distortion decays more slowly than the universe is expanding since this would build up a large cumulative distortion with increasing time. Collins and Hawking also make use of two general constraints on the matter fields within the cosmologies. The first, the dominant energy condition (DEC)[40], requires $T^{00} \geqslant |T^{ab}|$ whilst the second, the positive pressure criterion (PPC)[41] requires $\sum_{k=0}^{3} T_{kk} \geqslant 0$. Although the first of these will be microscopically violated in the quantum processes[42] described above, it should still be valid 'on the average' or on large spatial scales. Collins and Hawking consider the most general homogeneous perturbations to the flat, ($k = 0$), and open ($k = -1$) Friedmann space-times. the most general is of the Bianchi VII$_h$ type requiring one more arbitrary constant to specify the metric than in the type VII$_0$ case which generalises the $k = 0$ isotropic model and is a special case of the VII$_h$ generalisation of an open, isotropic universe. The Collins–Hawking analysis yields:

> Theorem 1 (ref. 1): If DEC and PPC are satisfied then the set of homogeneous initial data giving rise to models which approach isotropy is of measure zero in the space of homogeneous data.

That is, as defined by I1–I4 isotropy is in general an unstable property of an expanding universe independent of its equation of state. In proving this theorem they assumed that conditions I1 and I3 held and showed that this implied I3 and I4 could not. This tells us that the inevitable instability revealed by their theorem is associated with a non-decaying shear mode violating I3 and/or I4. In fact, examination of the VII$_h$ model close to isotropy reveals $\sigma/\theta \rightarrow$ constant as $t \rightarrow +\infty$. Thus, $\beta \sim t$ and an ongoing cumulative distortion arises to first order. There could of course also exist in the VII$_h$ perturbation a vortical instability violating I2 which is explicitly suppressed by the method of proof.

Next, Collins and Hawking fix on a preferred subset of cosmologies—those in the neighbourhood of the zero energy ($k = 0$) models and their homogeneous perturbations of type VII$_0$. In this case the behaviour qualitatively changes since the stability is in fact sensitively dependent upon the particular matter content of the space-time—as might be anticipated since these models, by definition, contain sufficient matter to influence and balance the expansion energy at all times. (In the open VII$_h$ models the asymptotic behaviour is dominated by kinematic and geometrical effects and all memory of realistic matter fields is lost as $t \rightarrow \infty$.) In order to arrive at a strong result regarding zero energy universes CH make the strong assumption that the matter content of the unperturbed isotropic model be just pressureless dust, ($p = 0$ state), and that traceless radiation fluids enter only as components of the perturbed matter currents. With this addition they prove:

> Theorem 2 (ref. 1): Let S be the subspace of type VII$_0$ initial data in the space of all homogeneous initial data. If the unperturbed Friedmann model contains dust matter and the perturbed matter content be comprised of dust and zero rest matter with tracefree stress tensor satisfying DEC, then, there exists an open neighbourhood of the $k = 0$ Friedmann initial data such that all data in this neighbourhood give rise to models which isotropise.

Thus, if a dust-filled universe lies sufficiently close to a state of zero total energy then it is stable against the development of anisotropy via homogeneous gravitational wave modes concordant with its global topology. (There may, of course, exist additional inhomogeneous gravitational wave perturbations to which it is unstable; see Bonnor[43,44], but his models are not general.)

From theorems 1 and 2 Collins and Hawking could draw either of two conclusions. Either: (i) The Universe is young; it is not of zero measure and is presently anisotropising under the action of generic homogeneous perturbations which have had, as yet, insufficient time to grow noticeably out of the linear regime. Or: (ii) the Universe is in the neighbourhood of the zero total energy state, the most general homogeneous perturbations admitted by its geometry are of Bianchi type VII$_0$ and decay in time. The Universe is thus isotropising but is of zero measure in the metaspace of all possible cosmological initial data sets. Collins and Hawking prefer option (ii) and justify its relative unlikelihood by appeal to an anthropic[6–8] argument to the effect that galaxies, and hence life supporting environments rich in biologically advantageous heavy elements, would only be expected to arise from such special intial data sets. Conclusion (i) was regarded as unsavoury because it requires our existence as observers to arise in a special interval of cosmic time before the anisotropy has a chance to grow large. Such an objection seems inconsistent since the same 'anthropic' principle used to explain the special binding energy necessary to support (ii) would also defend this no less special assumption required to uphold conclusion (i). Also the arguments invoked to incorporate the Anthropic Principle seem unconvincing given our present knowledge of galaxy formation. For, we might claim, the main problem in explaining the presence of protogalaxies by quasi-statistical fluctuations from homogeneity in the initial state is that these fluctuations do not appear to grow fast enough to give a self-consistent explanation for galaxy formation in any Friedmann universe, whatever its binding energy. To provide understanding of the later nonlinear stages of galaxy formation this difficulty is usually side-stepped and appropriate initial amplitudes simply postulated at some *ad hoc* initial epoch which will guarantee the present structures. Such a procedure really explains nothing of course. *Ad hoc* initial amplitudes will indeed allow flat Friedmann universes to produce bound inhomogeneities by the present epoch as Collins and Hawking wish but although the growth of relative overdensities is exceedingly faster (slower) in closed (open) background universes, the presence of galaxies in these backgrounds can also be explained by initially larger (smaller), but equally *ad hoc*, initial fluctuations.

Before examining the stability of Friedmann universes in more detail, we harmonise two apparently contradictory results, which might otherwise lead to confusion. In an earlier paper Collins and Hawking[45] also examined the behaviour of homogeneous, gravitational wave perturbations to Friedmann models and deduced the precise constraints placed upon the present shear and vorticity of the Universe by the microwave background isotropy over large angular scales. In performing this analysis they showed there exists a shear distortion mode growing in time $(\sigma/\theta \sim t^{2/3})$ if the Bianchi VII$_0$ model is linearised about the flat Friedmann universe. This appears to explicitly contradict theorem (2) of Collins and Hawking quoted above in the light of their isotropisation condition I3 ($\sigma/\theta \rightarrow 0$ as $t \rightarrow \infty$). However, a closer examination reveals that neither conclusion need be in error. In this earlier paper Collins and Hawking[45] discover the following unstable Bianchi VII$_0$ shear distortion mode to a flat, dust-filled Friedmann model:-

$$\begin{gathered}\sigma_{32} \sim \int \tau^{-\frac{1}{2}}[DJ_{3/2}(2\tau) + EJ_{-3/2}(2\tau)]\,\mathrm{d}t \\ \theta \sim t^{-1} \text{ where } \tau \sim t^{1/3} \text{ and } \dot{D} = 0 = \dot{E};\ `.\text{'} = \mathrm{d}/\mathrm{d}t\end{gathered} \tag{2}$$

To exhibit the short time behaviour of this mode we may use the standard small parameter expansion of the Bessel functions to obtain to first order;-

$$\sigma/\theta \sim At^{2/3} + Bt^{-1};\ \dot{A} = 0 = \dot{B}$$

and there indeed appears an anisotropising A-mode of VII$_0$ type close to the flat isotropic model over short times. However, the presence of the Bessel functions in (3) indicates that the shear mode is oscillatory over large time intervals. Using the boundedness of the oscillatory component we do indeed find the VII$_0$ model ($p = 0$), to tend asymptotically to the flat Friedmann model over large times and

$$\sigma/\theta \sim \alpha t^{-2/3} + \beta t^{-1};\ \dot{\alpha} = 0 = \dot{\beta} \quad \text{for } p = 0.$$

The short time expansion used in ref. 45 thus traces the initial growing phase of an oscillatory but asymptotically decaying function.

We now turn to consider the new consequences for the Collins–Hawking analyses from our arguments above regarding the inevitable asymptotic radiation domination of a marginally bound universe in the far future because of baryon non-conservation by the gravitational interaction. This significantly alters the conclusions drawn from theorem (2) of Collins and Hawking regarding the asymptotic dynamical state of universes close to zero total energy undergoing generic homogeneous perturbations. These universes will no longer isotropise, but in general will become vortically unstable at late times. To understand intuitively why this is so consider the newtonian dynamics of a ball of expanding fluid with radius R subject to a small rotational perturbation of angular velocity ω. The angular momentum of this expanding ball is given by $J = I\omega \sim MR^2\omega \sim (\rho R^3)R^2\omega$. Now for a perfect fluid with equation of state $p = (\gamma - 1)\rho$, conservation of mass requires $\rho \sim R^{-3\gamma}$ and thus $\dot{J} = 0$ requires $\omega \sim R^{3\gamma-5}$ with the associated linear velocity evolving as the ball expands as $v \sim R\omega \sim R^{3\gamma-4}$. Thus for newtonian ever-expanding universes filled with radiation $(\gamma = 4/3)$ the velocity, $\dot{v}$, approaches a constant value, violating isotropisation condition 12 of Collins and Hawking. However, this is in fact, physically, a growing instability. Inspection of the Raychaudhuri equation[46,47] governing the general kinematics of the fluid ball is (in the relativistic or newtonian case):

$$3\frac{\ddot{R}}{R} = 2(\omega^2 - \sigma^2) + \nabla_a \cdot A_a - \frac{1}{2}(\rho + 3p)$$

(where A_a is the fluid acceleration), showing that the dynamical influence of the vorticity is gauged by the contrast parameter $\omega^2\rho^{-1}$ which expresses the ratio of the centrifugal energy driving distortions to the isotropy-inducing matter stresses, We have, for small anisotropies, $\omega^2\rho^{-1} \sim R^{9\gamma-10}$. So, for a radiation fluid, (just $p \geqslant \rho/9$ on average suffices), a growing vortical instability develops as the fluid expands which will create a pancake-like or cigar-like configuration and rapidly increasing deviation from sphericity when $\omega R/\dot{R} \sim 1$. A newtonian universe with near radiation matter content would become increasingly dominated by the energy of random and rotational motions rather than the inertia of its rest-mass content. This is in complete contrast to the fate of a dust, $(\gamma = 1)$, ball where the vortical effects die away as $\omega^2\rho^{-1} \sim R^{-1}$ with the expansion. We shall confirm this behaviour with a fully relativistic derivation below, in which case the ball of fluid will be infinite. This simple argument also exhibits certain weaknesses of the CH isotropisation conditions. For instance, condition I2 allows a model to be classed as isotropising if $v \to 0$ as $t \to \infty$ even though $\int v\,dt \to \infty$ and thus the cumulative distortion from the velocity or vorticity perturbations leads to an aspherical configuration. We really require a stronger criterion: that the cumulative effect of the vorticity is non-increasing. By analogy with I4, a possible criterion would be

$$\Omega = \int_0^t \omega\, dt \to \lambda \text{ as } t \to \infty;\ \dot{\lambda} = 0.$$

For example, in a universe close to the flat, Friedmann model $R \sim t^{2/3\gamma}$, and conservation of angular momentum indicates that $\Omega \sim t^{(9\gamma-10)/3\gamma}$. Vortical effects will not lead to cumulative distortions if $\gamma < 10/9$ in agreement with the other criterion used above to discuss vortical instability, namely that $\omega^2/\rho \sim (\omega/\theta)^2$ decay as $t \to \infty$ for isotropisation, (this condition is analogous to condition I3 on the shear). These results indicate that there exist homogeneously expanding newtonian universes which may become increasingly far from isotropy as $t \to \infty$ due to their vortical instability and yet be classified as 'isotropising' by the Collins–Hawking criteria. Furthermore, flat newtonian universes may exhibit vortical instability whenever their fluid content satisfies $p > \rho/9$ and in particular radiation dominated universes are unstable.

It can be demonstrated that this vortical instability arises also in relativistic cosmology, as one might anticipate, since it is a consequence only of a fundamental invariance principle—the conservation of angular momentum. For concreteness we consider the homogeneous Bianchi VII$_0$ model (which generalises the flat Friedmann model) filled with radiation to demonstrate the instability; but the instability exists for all $p \geqslant \rho/9$ fluids. By vorticity we shall mean the rotation of matter about an observer moving with the matter, relative to an inertial frame defined by gyroscopes. the peculiar velocity will represent the velocity of the matter relative to the surfaces of constant homogeneity. We use the notation of Collins and Hawking[1] with our $R = e^{\alpha}$ and $\rho = \mu$ as scale factor and density.

A homogeneous cosmological model is defined as one which admits a three-parameter group of isometries, simply transitive on a family of space-like hypersurfaces[48]. Collins and Hawking[1] label these surfaces by t chosen so that $g^{\mu\nu}t;_\mu t;_\nu = -1$ and the metric has the form $g_{\mu\nu} = -n_\mu n_\nu + g_{AB}E^A_\mu E^B_\nu$ where $g_{AB} = R^2(e^{2\beta})_{AB}$ with β trace-free and $n_\nu = -t;_\nu$ is normal to the surfaces of homogeneity (Greek indices run 0–3 and Latin 1–3). Thus, spatial homogeneity implies $\rho;_\nu = -\rho n_\nu$ for a scalar, ρ. Consider a radiation fluid with

$$T^{\mu\nu} = \tfrac{4}{3}\rho U^\mu U^\nu + \tfrac{1}{3}\rho g^{\mu\nu}$$

The conservation equation $T^{0\nu};_\nu = 0$ yields

$$[\rho(U^0)^{4/3}R^4]^{\cdot} = -\tfrac{4}{3}\rho(U^0)^{1/3}C^A_{AB}U_C R^2(e^{-2\beta})_{BC} \qquad (4)$$

where C^A_{CB} are the structure constants of the homogeneous, space-group symmetries. The acceleration by the fluid pressure is given by another conservation equation as

$$\tfrac{4}{3}\rho U^\mu{}_{;\nu}U^\nu = -\tfrac{1}{3}\rho_{;\nu}h^{\mu\nu} \quad \text{where } h^{\mu\nu} = g^{\mu\nu} + U^\mu U^\nu$$

so:

$$[\rho^{1/4}U_A]^{\cdot} = \rho^{1/4}(U^0)^{-1}C^B_{CA}U_B U_D R^{-2}(e^{-2\beta})_{CD} \qquad (5)$$

The components of the vorticity vector are defined as $\omega^\mu = \eta^{\mu\nu\lambda\rho}U_\nu U_{\lambda;\rho}$ where $\eta^{\mu\nu\lambda\rho}$ is the alternating tensor. Thus,

$$\omega^A = R^{-3}\varepsilon_{ABC}[\tfrac{1}{2}C^D_{BC}U_D U^0 + U_B\dot{U}_C] \qquad (6)$$

and

$$\omega^0 = \tfrac{1}{2}R^{-3}\varepsilon_{ABC}[C^D_{BC}U_A U_D]. \qquad (7)$$

The Bianchi VII$_0$ model generalising the flat Friedmann universe, is of Behr-Ellis-MacCallum[49,50] class A having $C^A_{AC} = 0$. Thus, from (5) for small β, close to isotropy we have:-

$$(\rho^{1/4}U_A)^{\cdot} \sim \rho^{1/4}C^B_{CA}U_B U_C R^{-2}$$

(4) implies $\rho \sim R^{-4}$ thus,

$$(R^{-1}U_A)^{\cdot} \sim R^{-3}C^B_{CA}U_B U_C \sim R^{-3}[1 + 0(v^2)]$$

Thus to first order, perturbations in velocity and vorticity of this type evolve from the Friedmann background as $U_A \sim R$ giving the three-velocity squared as $v^2 \sim U_A U^A \sim$ constant and to first order for the vorticity vector, from (6) and (7) we have,

$$\omega^A \sim R^{-3}[\text{const.}\, R + RR] \sim R^{-2}$$

$$\omega^0 \sim R^{-3}[\text{const.}\, R^2] \sim R^{-1}$$

Thus, the vorticity scalar evolves $\omega^2 \sim R^{-2}$ in agreement with the simple newtonian arguments given above. Modifications due to nonlinear coupling with the shear are to be expected when the vorticity becomes large. Therefore, the flat, radiation-filled Friedmann universe will be unstable to the development of vorticity; this behaviour is not an artefact of the homogeneity of the perturbations and may be recovered from studies of inhomogeneous vector perturbations to isotropy[51]. Intuitively, we may see this from Raychaudhuri's equation which shows that when baryons and leptons have been eliminated by the mechanisms described in the last section the terms driving the expansion are $\rho_\gamma \sim R^{-4}$, the shear $\sigma^2 \sim R^{-6}$ and the rotational energy $\omega^2 \sim R^{-2}$ in the linear regime. For large R the rotational energy clearly dominates. In models with open spatial sections $(k = -1)$, (type VII$_h$ being the most general homogeneous example containing the Friedmann, open model), such an effect also competes with the spatial curvature terms $\sim R^{-2}$ and the relative strengths of the curvature and rotation terms will determine the asymptotic behaviour. If the curvature effects dominate as $R \rightarrow \infty$ they will suppress the vortical instability and allow the shear instability $\sigma/\theta \rightarrow$ constant found by Collins and Hawking to control the future evolution. However, it is still possible for the spin to significantly determine the final state via its non-linear interaction, see for example refs 52, 53. This completes the argument that the 'heat death of the Universe' is sufficient to ensure all isotropic universes are unstable irrespective of their binding energy. The fate of perturbations to closed Friedmann universes was not considered by Collins and Hawking in ref. 1 but other studies indicate that the general homogeneous closed universe of Bianchi type IX does not 'isotropise' in any meaningful sense[39] as it approaches maximum volume. For instance, the spatial curvature does not tend to directionally equalise and will produce anisotropy in the Hubble rates.

Another conceivable cosmological artefact of eschatological significance is the possibility of a non-zero cosmological constant Λ whose presence introduces terms of the order of ΛR^{-2} in the energy evolution equations. This is of the same order as the vortical energy term ω^2 asymptotically in the radiation-dominated universe. We might thus suspect that in the $\Lambda > 0$ case, allowing ever-expanding universes, the isotropic stress induced by the presence of this hypothetical cosmic force field might be of sufficient magnitude to dominate the vortical energy. A negative Λ would essentially reproduce the closed universe evolution since it has been shown[54] that a space-time with $\Lambda < 0$ cannot expand forever: all timelike curves have a finite length $< 2\pi(3/|\Lambda|)^{1/2}$.

It is possible that the collective gravitational effects of density perturbations could be the predominant agent in driving the cosmological flow from homogeneity and isotropy in the large at late times. For example, an irregularity spectrum $\delta\rho/\rho \sim M^{-\alpha}$ contributes to the metric distortions as $\delta g/g \sim M^{(2/3-\alpha)}$. The preferred $\alpha = 2/3$ Zeldovich spectrum[32,55] is envisaged with metric perturbations constant on all scales as they enter the horizon. If a 'white noise', $\alpha = 1/2$, spectrum prevails then they would eventually dominate the dynamics as $M \rightarrow \infty$ and couple with the vortical motions to determine the asymptotic behaviour. It is not know, of course, if such spectra really do extrapolate to indefinitely large mass scales.

We have in this section completed a proof that physically realistic ever-expanding universes asymptotically deviate from isotropy—eternity is unstable.

Asymptotia

The future state of non-flat, ever-expanding universes is characterised[1] by a cumulative shear distortion in the expansion flow. That of the ever-expanding flat models is analagous to a relativistic vortex, for the dominant instability is due to the vorticity of the matter flow lines. In both cases the final state is characterised by increasing irregularity. However, these irregularities will not in general result in a breakdown of the global causal structure in the large; a generic homogeneous space-time is globally hyperbolic, which means that the future is determined by the initial data on some space-like hypersurface. Siklos has shown[56] that homogeneous space-times which violate global hypergolicity have two fewer free parameters than the most general spatially homogeneous space-times. He also showed that type VII_0 space-times which satisfy $R_{ab}K^aK^b > 0$ for all null vectors K^a cannot violate global hyperbolicity, and this inequality would hold in a VII_0 space-time which is dominated by randomly orientated radiation.

Although global hyperbolicity will hold on a large scale, it will be violated in the small in an ever-expanding universe. The complete evaporation of a black hole will generate a naked singularity[57] and this necessarily means a violation of global hyperbolicity. Thus, if one considers global hyperbolicity—the ability to predict the future—to be a property which must hold, even in the small, in any physically realistic space-time, then one is forced to conclude that the actual Universe is closed. Only in this case can an all-encompassing, final singularity intervene to prevent the inevitable formation of naked singularities from black hole evaporation.

The matter vorticity couples to the Weyl tensor in the second order[50], so the instabilities we have discovered and those of Collins and Hawking[1] imply that the Weyl tensor grows with time. Now Penrose has suggested[58,59] that the entropy of the gravitational field is proportional to "some suitable integrated measure of the size of the Weyl curvature". If this connection between the gravitational entropy and the Weyl tensor holds, then our results can be interpreted as saying that the entropy of the gravitational field increases with time. This is just what we would expect; the entropy of all fields should increase with time, unless the decrease of the entropy of one field is more than counter-balanced by the increase in the entropy of another. An asymptotic approach to a Friedmann space-time, which is the future behaviour of the universe envisioned by many cosmologists—in particular by Collins and Hawking[1]—would constitute a decrease in the gravitational entropy without a corresponding increase in the entropy of the other fields. The second law of thermodynamics tells us that this cannot happen (statistically speaking, it must be very improbable) and this is what we have found.

We have arrived at a final state for an ever-expanding universe which is somewhat different from the "state of eternal rest" pictured by the nineteenth century physicists. In our view the space-time geometry is becoming more and more irregular at very late times. Both pictures envision an asymptotic approach to a state of maximum entropy; our version of the heat death is different because we have included the gravitational entropy.

Time is a measure of change, and both versions of the heat death have fewer and fewer changes as asymptotia is approached. Thus, one might expect that physical time could slow down relative to proper time in the far future. Although the asymptotic state is reached only after infinite proper time in an ever-expanding universe, it is possible that it would be reached in *finite* physical time. Misner has argued[60] that proper time is an inappropriate measure of physical time near a singularity. Because changes occur with great rapidity (as measured in proper time), Misner contends that the singularity should have occurred in the infinite past as measured in physical time, though only about twenty thousand million years ago in proper time. A mathematically appealing timescale which has this 'Misner time property' of placing singularities at temporal infinity is the so-called York extrinsic time[24,61] York[61] has proposed foliating a space-time with spacelike hypersurfaces of constant mean extrinsic curvature, and defining time to be given by $T = -\frac{4}{3}K^a_a$, where K_{ab} is the extrinsic curvature of the hypersurface. ($K^a_a = K^1_1 + K^2_2 + K^3_3$ is the mean curvature: the sign is chosen as to make T increase to the future, and the factor 4/3 simplifies the expression of the dynamical Einstein equations). Such a foliation can be shown to exist in a fairly general class of closed universes[62]; and in closed universes, the foliation will also be unique[62,63]. If this foliation by constant mean curvature hypersurfaces exists and is unique in open universes also, then it would define an absolute time for the Universe. In ever-expanding universes with an initial singularity the York time varies between $-\infty$ at the singularity and zero at asymptotia. Hence if York time measures physical time in the far future, then an ever-expanding universe, which exists forever in future proper time, will continue to exist for only a finite physical time. Vaguely speaking, only a finite number of changes will occur in the future; the heat death puts an end to change.

Note that in closed universes, which have both initial and final singularities, York time varies[62] between $-\infty$ and $+\infty$. Closed universes thus have a finite future in proper time, but an infinite future in York time. If York time is indeed the appropriate measure of physical time near the final singularity, then the infinite future duration of a closed universe can be interpreted as saying that the gravitational field provides an unlimited source of free energy near the final singularity, and this permits an infinite number of changes—physical time intervals—to occur.

We close with a final speculation. One of the fundamental problems of statistical mechanics is accounting for the global increase of entropy without introducing a very strong stochastic assumption, such as the postulate of random phases or the assumption of coarse-graining, which is difficult to justify. As discussed in detail by Brush[19], the justification of this type of stochastic assumption has a subjective flavour about it. Coarse-graining, for example, generally requires an appeal to human inability to measure a difference between certain classes of states[64]. What is required is a proof of entropy increase which does not require such a stochastic assumption but uses only the equations of motion of the existing fields and particles (all time-reversible except for the super-weak T-violating interaction) and the universal initial conditions. Penrose's suggested connection between gravitational entropy and the Weyl tensor may provide a mechanism for such a proof. The present article and the work of Collins and Hawking indicate (but do not prove) that in homogeneous ever-expanding universes, the Weyl tensor will increase as one moves far away from a generic, conformally flat singularity. Thus, the increase of Penrose gravitational entropy follows from assumptions about the Initial Conditions: the initial singularity is both generic and conformally flat. Is the Penrose entropy the ultimate source of all entropy increase?

Punctuated evolution of tectonic style

R. B. Hargraves

Department of Geological and Geophysical Sciences, Princeton University, Princeton, New Jersey 08540

A continuous secular evolution in the vigour of mantle convection may have translated into a series of distinct stages in crustal tectonic style.

THERE is much debate about the nature and relative magnitude of the forces responsible for the motion of lithospheric plates[1]. The possibilities considered include the viscous drag of convecting asthenosphere and the gravitational push away from oceanic ridges, but it is the gravitational pull, or negative buoyancy, of the cold, subducting lithospheric slab which emerges as a major[2,3], if not the predominant[4–6], force. The age of crust being subducted today ranges from 5 to 175 Myr (ref. 6) and Atlantic oceanic crust ~200 Myr old has not even started, so clearly achieving a critical value of negative buoyancy is not the only cause of subduction. Some combination of these forces, and perhaps circumstances such as convergence and over-riding of ridge by continent, must be enough to trigger subduction, and cause the spectrum of subducting-crust ages. Nevertheless, if it is accepted that on a world-wide basis, negative buoyancy is the major force in this process, then this view has important ramifications with respect to Precambrian tectonic style.

Buoyancy

From a plate-tectonic point of view, buoyancy is measured relative to the average density of the asthenosphere. Crust, whether it is basaltic or granitic, is positively buoyant, whereas the cold peridotitic part of the lithosphere is denser than the hot asthenosphere. Overall negative buoyancy of lithosphere results from the cooling of oceanic plates as they recede from ridges, and the denser, mantle part of the lithosphere thickens relative to the thin positively buoyant crust.

If higher average heat flow implies a thinner lithosphere, then negative buoyancy must have been less important in the past. Consideration of the possible previous magnitude of the terrestrial heat flux[7], forces associated with earlier, more vigorous convections[8], and their gradual temporal evolution, forms the basis for the speculation developed below, that three critical stages in the evolution of tectonic style on Earth may have occurred: (1) initially any thin crust formed was completely recycled by viscous drag forces associated with rapid convective circulation. (2) As these forces diminished, crust accumulated like scum, possibly to form a globe encircling layer. As such crust thickened by continuous outpouring of lava and tectonic

0028–0836/78/0276—0459$01.00

compression, it would have been recycled by remelting at the base. Archean terrains have features compatible with this hypothesis. (3) Further decrease in heat flux and increase in negative buoyancy culminated in subduction of relatively thinner segments of this crustal scum, initiating plate-tectonics, and development of the present continent–ocean dichotomy. The essential details of this argument are as follows.

Continent–ocean dichotomy

Dissipation of up to 45% of the contemporary heat flux is attributed to the creation and cooling of new oceanic lithosphere[9]. The balance, produced by some combination of radioactive decay within the lithosphere (the upper continental crust in particular[11]) and a sublithosphere flux is conducted to the surface. (Although thought necessary to explain the observed heat flow values, the source of the flux is not clear. It could be associated with the small-scale convection of McKenzie and Weiss[8], or Richter and Parsons[12], or be generated by viscous dissipation associated with convective flow, as suggested by Schubert *et al.*[13].) The manner of dissipation of the significantly higher Precambrian heat flux[7,8] is becoming a focal point of the debate concerning Precambrian tectonic style[14–16] and whether or not plate tectonics were operating[17]. The more conventional uniformitarian view assumes that the mechanism involving the creation, cooling and subduction of new lithosphere, which accounts for 45% of today's flux, must have been at least proportionately more vigorous in the past[18]. In this view a greater length of spreading ridge, or faster spreading, is required to accommodate the higher flux. But this cannot be the case if negative buoyancy is the critical or dominant component of the plate driving force. Faster spreading would imply less time between ridge and trench, and greater ridge length would imply less distance between ridge and trench; in either case less cooling and hence less negative buoyancy could be achieved.

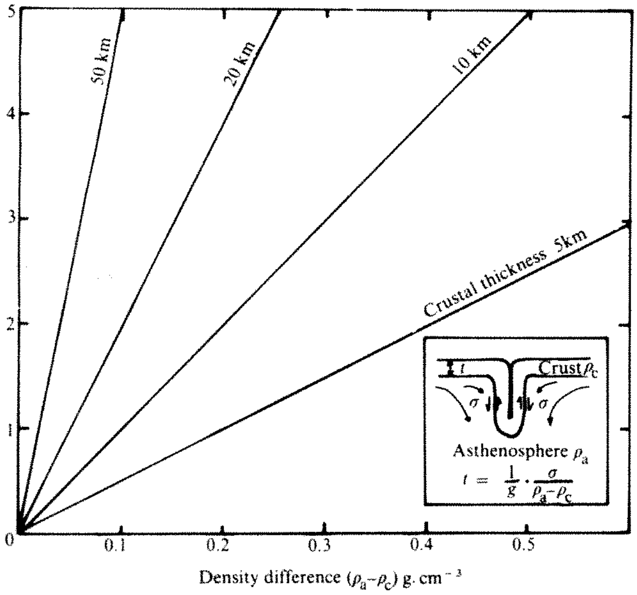

Fig. 1 Thickness of positively buoyant crust which would be in equilibrium with an asthenosphere-imposed downward-dragging shear stress (see inset). Curves for various crustal (or lithospheric) thicknesses are plotted as a function of shear stress and positive density difference ($\rho_{\text{crust}} > \rho_{\text{asthenosphere}}$). $t = (1/g)(\sigma/\bar{\rho}_a - \rho_c)$.

With respect to contemporary plate tectonics, buoyancy-powered subduction can occur as soon as the average density ($\bar{\rho}$) of the lithosphere is greater than the underlying asthenosphere. Basalt ($\rho = 3.0$)[19], by itself, is positively buoyant with respect to the asthenosphere ($\bar{\rho} \sim 3.22$); it is the growth of cold mantle lithosphere ($\bar{\rho} \sim 3.30$) which increases the average density and eventually renders the lithosphere negatively buoyant. If, as has been claimed[20], the residual periodotite from which the basalt was derived is also positively buoyant, then even more cooling and growth of lithosphere is required to achieve negative buoyancy.

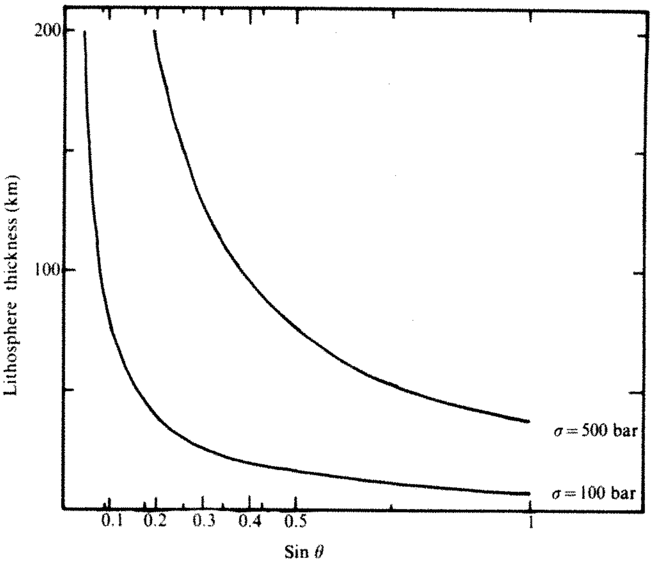

Fig. 2 Differential shear stress (σ) which would be generated along the Mohorovic discontinuity as a function of inclination or tilt (θ) of this boundary and total lithosphere thickness. Differential stress arises from positive buoyancy of crust relative to negative buoyancy of cold mantle part of the lithosphere. Model assumes lithosphere, isostatic with asthenosphere ($\rho_a = 3.22$) and consisting of 17.7% crust ($\rho_c = 2.85$) above mantle ($\rho_m = 3.30$). $t_{\text{lithos}} = 7.6\sigma/g \sin\theta$.

The average magnitude of the negative buoyancy required to trigger buoyancy-powered subduction may be approximated in terms of the average lithosphere subducting today which is about 80 Myr old, 75 km thick, and has a heat flow of ~60 mW m^{-2} (1.4 HFU)[21]. If twice this heat flow (120 mWm^{-2}, ≈lithosphere 20 Myr old, ~40 km thick) is taken as the maximum commensurate with buoyancy-powered subduction, then there was a time earlier in Earth history before which it was unlikely to occur. Even using the cooler (relative to a chondritic Earth) extrapolated heat flow curve of Wasserburg *et al.*[7], the average surface heat flow from the Earth was in excess of (120 mW m^{-2}) until ~1,500 Myr after the Earth formed[6]. On this basis subduction, powered primarily by negative buoyancy forces, could not have started until relatively late in Earth history.

Viscous drag

Although the lithosphere was likely to have been thinner when heat flow was higher, the viscous drag of more rapidly circulating asthenosphere would certainly have been stronger. Assuming that the Earth was hot enough for mantle-wide convection soon after its formation, McKenzie and Weiss[22] conjectured that originally this viscous drag force may have been as much as

Table 1 Correlation between tectonic sequence and Earth history

Tectonic sequence	Date (Myr BP)	Stages in Earth history
Viscous drag subduction	→ ~3.6 by	Complete cycling of crust
Scum—crust	3.6 → ~2.6 by	Archaean granite—greenstone terrains are remnants
Buoyancy powered subduction		
(1) Decoupling of mantle lithosphere from crust	2.6 → ~0.6 by	Cause of Proterozoic intracratonic mobile belts
(2) Complete lithosphere subduction	2.6 → 0	Growth and maintenance of ocean: continent crustal dichotomy

5×10^7 Nm^{-2} (500 bar). This, they pointed out, would have been more than sufficient to fracture the lithosphere or crust. At this time, however, the lithosphere may well have been so thin as to consist of little more than positively buoyant basaltic crust floating on asthenosphere. Being gravitationally stable, such a lithosphere would resist subduction, and it would thicken by overthrusting above the downwelling convective zone. It is possible, however, that the viscous pall of downwelling asthenosphere could effectively drag even positively buoyant thin crust (or depleted mantle lithosphere fragments) back into the mantle. The relationships among viscous drag force, density contrast and lithosphere thickness necessary for this to occur are shown in Fig. 1. Even though the model used is oversimplified, it shows, for example, that lithosphere slabs 10 km thick with an average density contrast of +0.25 g cm^{-3} could be dragged down by a shear stress of ~250 bar. On these terms, it can be claimed that the early Earth may have consisted of a mosaic of small, thin plates, circulating with the vigorously convecting asthenosphere beneath, a model similar to that proposed by McKenzie and Weiss[6].

As heat flow declined, the velocity of the circulating asthenosphere and the associated viscous drag force would presumably decrease. With slower spreading, however, the average age of the plates would increase, the mantle component of the lithosphere would become thicker and the average positive $\Delta\rho$ would decrease, eventually becoming negative. All the latter changes would make the lithosphere more subductible. Thus subduction driven by viscous drag forces may well have evolved continuously into buoyancy-powered subduction such as we have today.

Discussion

Two aspects of this simple evolution, however, merit further consideration. First, before the onset of buoyancy-powered subduction, a stage may have intervened when the viscous drag was insufficient to pull down positively buoyant lithosphere. As a result, crust may have accumulated like scum until, conceivably, the whole Earth was covered. Recycling of this crust would have occurred because thickening by tectonic compression and continued outpouring of lava on the surface would inevitably have led to remelting at the base. Eventually, however, the right combination of thin crust, relative to thick mantle lithosphere, necessary for critical negative buoyancy, would have been achieved somewhere on the globe, and buoyancy-powered subduction would have commenced. Complementary spreading would form protooceanic crust, and the growth of the ocean–continent crustal dichotomy could have begun. Second, cooling and thickening of mantle lithosphere beneath thicker crust could lead to their decoupling and independent 'subduction' of the former. Decoupling of lithosphere from crust would require that the shear stress on the Mohorovicic discontinuity exceed some critical value.

Such a differential shear stress could arise from the intrinsic positive buoyancy of crust relative to the negative buoyancy of the cold mantle lithosphere below. As long as the density gradient was perpendicular to the gravitational force (that is, the Moho was horizontal), however, there would be no differential shear stress. But if the discontinuity became tilted, a shear stress would be developed which might suffice for decoupling. Assuming that the average lithosphere was isostatic with respect to asthenosphere (that is, $\bar{\rho}_l = \rho_a$), then the relationship between lithosphere thickness and tilt of the Moho needed for decoupling, for two critical shear stresses, is shown in Fig. 2. With a 25-km thick crust, a tilt of 6° would cause a Moho shear stress of 100 bar; such a tilt would be associated with a warp of half amplitude 15 km and a half-wave length approaching 300 km. When heat flow was higher, the temperature at the Moho was higher, and the critical shear stress for decoupling was less. Decoupling by this means, therefore, seems feasible. Stresses associated with such independent subduction of mantle lithosphere slabs, decoupled from crust above, may have been responsible for the deformation in intracratonic mobile belts common in Proterozoic terrains[23]. Today, perhaps, with subcratonic Moho temperatures averaging 500° C, and thicker lithosphere, the tilts and shear stresses necessary for decoupling cannot be achieved.

The degree of validity of the simple relationships proposed here is not known. Even if they are pertinent, the temporal evolution of the magnitude of the parameters involved in the relationships is also unknown, but the trend with the inescapable decline in heat flux must be correct. As Table 1 shows, the appeal of the tectonic sequence postulated lies in the possible correlation with the observed major stages in Earth history.

I thank S. T. Crough, K. S. Deffeyes, W. J. Morgan and L. Rossbacher for helpful discussions.

Injection events in ocean history

Hans R. Thierstein & Wolfgang H. Berger
Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093

The reconnection, with the world ocean, of temporarily isolated ocean basins results in injection either of hypersaline waters favouring abyssal stratification and stagnation, or of brackish waters from high latitudes leading to a low salinity surface layer. Mass extinctions and sudden climatic change are closely associated with Arctic injection.

SEVERAL major palaeoceanographic events have become well defined recently through the results of deep-sea drilling[1,2]. We propose here that several of these events are manifestations of the same type of occurrence, that is, the injection into the world ocean of saline or of fresh water from a temporarily isolated large basin. We first enumerate the events, and then consider the evidence for isolated basins and the timing of opening, the

0028-0836/78/0276—0461$01.00

physical processes governing the injection, and the compatibility of our model with published data on isotopes and carbonate preservation. We also present the first detailed stable isotope stratigraphy across the Cretaceous–Tertiary boundary and interpret it in terms of the injection model.

Major events of the past 100 Myr

The phenomena to be explained are: (1) the mid-Cretaceous event or series of events (Aptian–Turonian) which produced worldwide changes in carbonate deposition[2] and which brought notable changes in marine biogeography, especially that of reefs, bivalves and nannofossils[3–6]; (2) the Cretaceous–Tertiary boundary event which brought about great changes in plankton assemblages[7–14]; (3) the Eocene–Oligocene event, which is marked by a sharp decline in diversity of plankton[15–17], a change of benthos[18], a pronounced lowering of the CCD[19,20] and by a sudden drop in the temperature of deep waters[21–23]; (4) the Miocene–Pliocene boundary which is marked by diversity decline of planktonic foraminifera[15,16] and by cooling[24] and Antarctic ice expansion[25], and which heralds the onset of northern glaciations[21,25,26].

Many explanations have been proposed for these events, especially for the Cretaceous–Tertiary boundary, which produced the most profound changes in evolutionary history during the past 200 Myr; these hypotheses are reviewed elsewhere[27,28]. Here we ask whether these events might be linked by a common oceanographic phenomenon: exchange with a previously isolated basin. Such an exchange was recently proposed for the Cretaceous–Tertiary boundary[29].

Recent palaeogeographic maps[30] show that preceding each major event a large isolated basin existed whose exchange with the world ocean was restricted to a more or less severe degree. In the Aptian, salt was deposited in a restricted proto-South Atlantic[31]. The same basin received highly carbonaceous sediments in late Aptian to Albian time[2,32], showing its restricted status. In the Maastrichtian, the Arctic Ocean was essentially isolated with both the Labrador Passage and the Greenland Passage closed[30,33]. In the Eocene, a similar situation prevailed, with the Labrador Passage and the Norwegian–Greenland seas closed[30]. In the early Miocene the western Tethys became isolated by closure of Africa and Eurasia[26] and in the late Miocene it went dry intermittently and accumulated large salt deposits[34–37].

In all four cases, the restricted basins seem to have opened for full exchange with the world ocean at about the time of crisis, and perhaps exactly coincident with it. Assuming that this is more than a coincidence, are there physical reasons that such an event should lead to worldwide biological and geochemical changes?

We think there are: the global heat budget requires polewards transport of latent heat, especially with warm climate in high latitudes[38]. Thus, each of the restricted basins is likely to be either more saline (proto-South Atlantic, Mediterranean) or fresher (Arctic) than the world ocean. A sudden onset of exchange, therefore, would upset the existing global density stratification, with profound effects on ecological stability and fertility of the ocean.

In principle, a strong influx of heavy (very saline and/or very cold) water will isolate abyssal waters from overlying intermediate and shallow waters, by increased density stratification. Likewise, a strong influx of fresh water or very warm water, will isolate the upper ocean layer from the waters at depth. However, the exact effect of a catastrophic influx depends on the existing stratification. If, for example, a widespread oxygen minimum exists, influx of heavy water can instantaneously lift the minimum towards shallower depths, provoking a global upwelling phenomenon (the surface water withdraws into the newly opened basin). Other sequences can be readily envisaged; for example, with intruding layers becoming sandwiched between existing ones and thus decreasing stability rather than increasing it. We are concerned here, however, with injection of waters of extreme density difference, which sink to the bottom or float on top of the ocean.

Cretaceous anoxic events

In the case of the mid-Cretaceous period of anoxic events[31,39,40] we postulate that the stability of the water column was greatly increased, first in the North Atlantic and later—and sporadically—in the entire Pacific by saline outflow to the north from the early South Atlantic starting in the Aptian. These brine injections reinforced haline stratification in an already salinity-layered world ocean with oxygen-poor and carbon dioxide-rich deep waters[2,41]. Deep water exchange between North and South Atlantic may have begun sometime in the Cenomanian, shallow-water exchange of normal salinity having been demonstrated for at least as early as the late Albian[42].

We envisage the mid-Cretaceous South Atlantic as being filled with heavy saline waters, to a level commensurate with the Walvis–Rio Grande sill. These saline waters were produced on surrounding partially flooded shelves and possibly also from the dissolution of pre-existing exposed Aptian salt deposits. The South Atlantic would have acted as a source of heavy bottom water for some considerable time, with pulsing supply, in response to climatic variation on the shelves. This pulsing would have translated into intermittent anaerobism, as reported by Lancelot, Seibold *et al.*[43]. Supply of nutrients and preservation of organic matter in the Atlantic were provided by estuarine circulation[44,45]. The South Atlantic surface and intermediate waters were estuarine with respect to the southern ocean, with intermediate cold waters moving north on top of the saline bottom layer and upwelling in the basin. This intermediate water brought the austral faunas described by Premoli Silva and Boersma[46]. The North Atlantic was estuarine with respect to the Pacific with intermediate cold waters moving east on top of the saline deep layer, and subsequently upwelling especially in the eastern Atlantic basin. Both a broad oxygen minimum and bottom-near oxygen deficit resulted, which lasted through Turonian time[2,47]. The oxygen minimum also reached into adjacent shelf sea areas, by estuarine shelf circulation, generating "tremendous areas of well laminated, dark organic rich shale"[48] deposited in conditions unfavourable for benthic foraminifera[49]. At the foot of the eastern continental slope, the abyssal saline layer favoured the precipitation of dolomite, and, through the accumulation of CO_2 of ankerite and siderite, as described from Site 138[50]. The mid-Cretaceous anoxic period ceased (for the deep sea) when the South Atlantic ceased to be restricted but became a throughway for austral cool deep waters. These waters were able to mix with the tropical saline inflow because of their similar densities.

Cretaceous termination

In the case of the Cretaceous termination[11,28], exchange with a previously isolated Arctic Ocean filled with fresh or very low salinity water has been postulated[29]. The isolation occurred during the latest Cretaceous regression. On tectonic opening of the Labrador Passage, the light water of the Arctic would be readily displaced by the surficial salt water of the North Atlantic. Assuming from palaeogeographic maps[30] and from present conditions that the volume of the Arctic is about 1.3% of that of the world ocean, and assuming complete isolation, we obtain a layer of fresh water some 53 m thick, as a maximum estimate. Mixing this layer to one-half the normal salinity makes a layer over 100 m thick. Hence it includes the entire photic zone. The salinity would be such that open ocean plankton (plus its trophic dependents and stenohaline shallow water benthos) could not survive, as observed[7,9,10,14,27,51]. Coastal plankton, being less sensitive to lowered salinity[52] and perhaps certain abyssal plankton, such as deep-living radiolarians, would be much less affected. Likewise, deep-living benthics would not be affected. Indeed, deep-living benthic foraminifera do not show unusual changes at the boundary (refs 53, 54 and L. Tjalsma, personal communication.). The ensuing short-term climatic changes would affect land animals and to a lesser degree land plants[35].

Once the unfit planktonic species had been eliminated, successive exchange events (from slight changes in sea level or in sill tectonics) produced intermittent Arctic injections and blooms of opportunistic survivors. Such blooms are well known from the earliest Tertiary, involving both thoracosphaeres and braarudosphaeres[13,14,56–60]. When the Labrador Passage had widened sufficiently[61], isolation of the Arctic ceased and so did injection of fresh water. Radiation of plankton species followed in the late Palaeocene[15–17].

Eocene termination

In the case of the Eocene–Oligocene boundary we again postulate exchange with a previously isolated Arctic, the isolation being produced by regression and by closing the Labrador Passage sometime during the Eocene[30]. This time the opening is through the Greenland Sea Passage[62]. Again, we assume the Arctic was fresh or had very low salinity, on the basis of the requirement that latent heat must be brought into this polar area in sufficient amounts to keep it ice free. The Eocene termination did not compare with the Cretaceous one in severity; we ascribe this to a more gradual water exchange, to the lack of a maximum exchange event, to a moderate brackishness of the Arctic at the end of the Eocene, or a combination of these. In other respects the two terminations are closely similar: open ocean forms do not survive and coastal forms flourish. We see small unspecialised planktonic foraminifera reminiscent of today's upwelling regions, and blooms of *Braarudosphaera* ('disaster forms' of Percival and Fischer[13]), as reported by Maxwell *et al.*[63] for the South Atlantic, and by Roth[64] for the Indian Ocean. In this view then the overall parallelism of plankton aspects of Palaeocene and Oligocene are due to the same cause.

The main difference between the two terminations (besides the amplitude) is the effect on benthic forms. At the Eocene–Oligocene boundary they are severely affected by the onset of production of cold bottom waters[18,21,23]. We ascribe this difference between the Maastrichtian and the Eocene termination to a feedback effect, which had negligible consequences in the first, but greatly increased snow cover (and possibly ice formation) in the Antarctic during the second. Our argument is derived from first principles of physical oceanography and climatology[65]. The introduction—presumably repeatedly—of a low salinity layer on top of the world ocean had the effect of temporarily obstructing the heat exchange between deep and shallow waters. As far as the heat budget of the Earth is concerned, such layering has the effect of reducing the ocean to a film of water hundreds of metres thick instead of thousands. Thus, the moderating influence of the ocean on climate is greatly reduced and seasonality increases correspondingly. The layering effect also increases the temperature of surface waters in the tropics, for the time of its duration. Both increased high latitude seasonality and increased tropical temperature favour transport of humidity to polar areas and its precipitation as snow. Once snow spreads, positive albedo feedback has a tendency to keep it there[66], resulting in a perennial polar high pressure cell with ensuing aridity.

In this view, then, the terminal Eocene injection event was the trigger for covering Antarctica with sufficient snow to move the polar front out to the shelf, which resulted in the production of cold bottom water. The cooling came at a time of regression, and albedo feedback through dry land areas[67] could be responsible for the overall drop in tropical temperatures in the Oligocene ocean[68]. We do not doubt the importance of the circumpolar current in this context[69] but merely argue that it is part of the setting, together with the polar position of Antarctica[70], and that the opening of Drake Passage (the timing of which is very uncertain) was not the trigger event. The botanical evidence indicates that vascular plants persisted on the Antarctic coast into the late Oligocene and that complete coverage by ice did not occur before Miocene time[71,72].

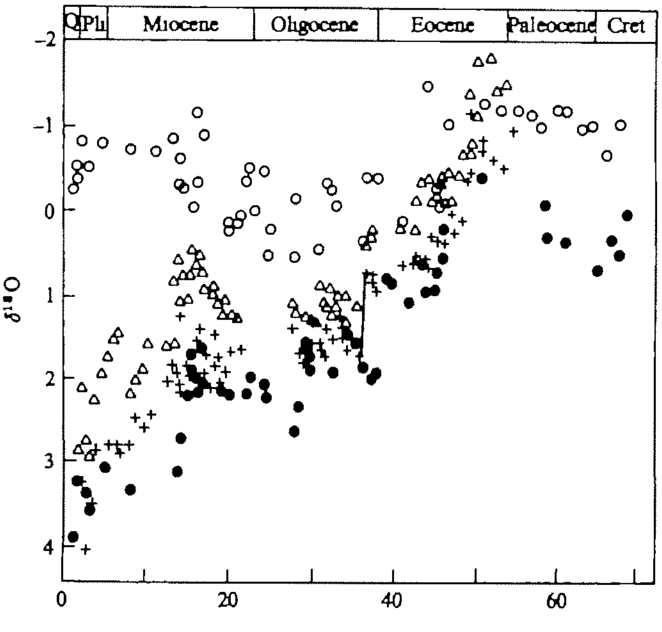
Messinian event

Isolation of the Mediterranean started in the early Miocene at its eastern end and culminated in the Messinian evaporite event[33–36,73–75]. We note the great amount of salt estimated to have been deposited in the basin during the latest Miocene (6% of ocean total)[37]. Many inundations were necessary to advect this salt[76] and intermittent water exchange with the world ocean probably occurred. In this view, the Mediterranean acted as a pulsating injector of saline waters, much like the South Atlantic some 100 Myr earlier. Again, stability of the world ocean was increased intermittently, with the described effect on seasonality, cooling and ice formation. An unusual cooling in high southern latitudes is shown for Site 284 (ref. 24) at the appropriate time, and the formation of ice strongly increased, according to the oxygen isotope curve from Site 281 (ref. 21). A temperature peak at the end of the Miocene is suggested for mid latitudes in the north-east Pacific[77]. The co-occurrence of warming in the subtropics and cooling in high latitudes would agree with our hypothesis. We do not doubt the importance of the correct setting for increasing the formation of ice, including the closing of the Panama Passage[78,79], but stress the role of stratification as a trigger of positive-feedback mechanisms.

Oxygen isotope stratigraphy

If stable stratification is associated with the events under discussion, and if it has the effects postulated, we should see warming in low latitudes and increased seasonality in high latitudes. Unfortunately, our hypothesis cannot be tested using the available information. The following statements illustrate the type of analysis necessary for evaluating the reality of injection events, and their ramifications (Fig. 1): (1) in the published records there is no substantial change of oxygen isotope values between the late Cretaceous and Palaeocene, although a minor temperature fall across the Cretaceous–Tertiary boundary seems to be indicated[80,81]. Thus, there is no evidence that the termination event acted as a trigger within a setting favouring change. Average temperatures were

Fig. 1 Oxygen isotope values of Cainozoic foraminifera (after Savin[68]). Data mainly from Douglas and Savin[81] and Shackleton and Kennett[25]. The short straight line at the Eocene–Oligocene boundary indicates the position of the drastic isotopic temperature drop (see ref. 23). Central North Pacific: ○, planktonic; ●, benthic; Southern Ocean: △, planktonic; +, benthic.



apparently fairly similar before and after the event. (2) The oxygen isotope values for early Eocene planktonic foraminifera of Site 277, south of New Zealand are the same or lighter than those from Site 47 on Shatsky Rise then located in the subtropics. For a 5 °C difference, for instance, between subtropic and subantarctic temperatures these southern values are too low by at least 1‰. We ascribe this difference to evaporation–precipitation effects[82], and postulate a difference in salinity of at least 4‰. Rainforests existed in Eocene time in southern Australia and in the Ross Sea area[72]. This supports our deduction from heat budget considerations of high rainfall in high latitudes. (3) The $\delta^{18}O$ values of low and high latitude foraminifera (and benthics) begin to separate in the mid-Eocene. This indicates that the global temperature gradient increased and supports our contention that the Eocene termination was a trigger event, accelerating the existing trend. (4) There is no indication of a sharp lowering of tropical temperatures at the very end of the Eocene. Our hypothesis would not favour such a sharp lowering (instead it calls for climatic instability). (5) The drastic mid-Miocene drop of high latitude isotope values, due to an unknown combination of making Antarctic ice[21] and of further cooling[68], occurs concomitantly with high tropical temperatures. Although we do not postulate injection for this event, we see the marked transgression at the time[83,84] as an event simulating injection of light surface water. The transgression leads to the formation of a warm water layer, by the additional capture of solar radiation on the flooded shelves.

We have not shown the available oxygen isotopes from the mid-Cretaceous as they are still too scarce for the type of analysis presented. Nannofossil data from the North Pacific[81] show maximum temperatures near the Albian–Cenomanian transition, as predicted by our hypothesis. The same is apparently indicated by data from European belemnites, although various interpretations are possible[85].

Carbon isotope stratigraphy

The data for carbon isotope stratigraphy have been summarised by Fischer and Arthur[60]. We agree with their conclusion that periods of strong oxygen minima correlate with the deposition of organic carbon which is enriched in ^{12}C (ref. 86) and with depletion of ^{12}C in carbonates[12,83]. However, over short timescales, we postulate that the oxygen minimum produced by an injection event will tend to enrich the plankton shells in ^{12}C (ref. 87).

In agreement with this expectation, we note marked enrichment with ^{12}C in the planktonic foraminifera just before the Eocene termination, in the data given by Shackleton and Kennett[21]. Also, a slight warming is indicated in the detailed oxygen isotopic curve of Kennett and Shackleton[23], just before the event, which again agrees with the concept of increased stratification as the trigger. Likewise, there is a remarkable enrichment in ^{12}C of *Uvigerina* from Site 284, at the very end of the Miocene[25]. We interpret this to indicate stable stratification and oxygen depletion with concomitant increase of dissolved ^{12}C, from combustion of organic matter. The stable stratification, by our hypothesis, is provided through Mediterranean injection.

Preservation stratigraphy

Injection events should produce a preservation signal, as they would change mixing rates of the ocean, and hence fertility of the photic zone and affect the p_{CO_2} of deep waters. As in the interpretation of all other signals, caution is necessary to separate effects of a trigger event from those of the change in setting which ensued.

For the Cretaceous–Tertiary boundary widespread dissolution has been proposed[12,88]. This idea is based on evidence from shallow sections, and may be correct for the upper water layers. In the sections at Caravaca (south-east Spain), Zumaya (Gulf of Biscay) and at Stevn's Clint (Denmark), for example, there is a dearth of carbonate in a thin boundary layer of clayey sediment deposited in anaerobic conditions[13,54,89–90]. A widespread oxygen minimum developing underneath a low salinity lid could produce such a signal. In the deep Atlantic, the transition is not marked by a dissolution event. In contrast, at Sites 356 and 384, for example, the foraminifera and nannoliths in the basal Tertiary (*G. eugubina* Zone) show excellent preservation[52,91–93]. At site 358 there is a preservation climax in the lowermost Palaeocene[91].

The Eocene–Oligocene event is marked by a sudden drop of the CCD from high, ridge crest elevation to abyssal depths[19,94–96] and in the ratio of planktonic–benthic forams[97] which can be interpreted as indicating improved preservation, and also decreased productivity[98].

Another clue to the type of signal one might expect is given by the last deglaciation, 14,000–9,000 yr ago, when large amounts of meltwater were injected into the global ocean which apparently resulted in stable stratification of surface waters[99]. This event was accompanied by a preservation spike which ended abruptly in a dissolution pulse[100]. A simple explanation of this sequence would be that surface fertility was lowered during maximum stratification, letting the deep waters move towards chemical equilibrium, and that dissolution started when productivity resumed in upper waters and supplied organic carbon to still stagnating deep waters. However, the interpretation of the deglacial preservation sequence is complicated by re-deposition of shallow water sediments at the end of the glacial and by Holocene carbonate build-up on the flooded shelves[101].

We believe that all three preservation spikes can be explained by a fertility crisis in the photic zone and ensuing saturation of bottom waters. In the case of the Maastrichtian–Danian boundary event excessively stable surface stratification may have prevented reflux of nutrients, and a widespread oxygen minimum might have destroyed available nitrogen[102–103]. The decay of stratification after the injection at the Eocene–Oligocene boundary was accelerated by the progressive replacement of haline circulation by thermal circulation[83].

For the mid-Cretaceous event, the evidence indicates a worldwide rapid shallowing of the CCD in the Aptian, a temporary lowering in the Albian–Cenomanian, followed by another dissolution pulse in the Turonian[2]. The variation in carbonate deposition is closely matched by enrichments in organic carbon in deep-sea sediments, which parallels a general change from low oxygen content (carbonaceous sediment) to ventilation (oxidised sediment)[60].

The mid to late Miocene dissolution climax[104,105] coincides with the beginning of isolation of the western Tethys, as well as a marked transgression[83,84]. Of special interest is a dissolution pulse across the Miocene–Pliocene boundary, resulting in a high concentration of the genus *Sphaeroidinellopsis*[91,106]. We believe this is due to an increase in deep-sea p_{CO_2} resulting from haline injection. This dissolution pulse is, incidentally, superimposed on a general trend of a falling CCD and improvement in preservation, showing that the terminal Messinian event does not produce the trend, although it may have accelerated the change at the boundary. In Core RC 12–66, from the east equatorial Pacific, maximum contrast of high and low carbonate values occurs at the end of Magnetic Epoch 5, near the boundary[107]. The dissolution event in the earliest Pliocene seems to be the most severe one over several million years (event X in Kaneps[108]). According to our hypothesis, this event in the Pacific and the *Sphaeroidinellopsis* zone in the Atlantic realm are both expressions of an increase in p_{CO_2} due to stable stratification.

The available information on isotopic stratigraphy and on preservation stratigraphy is compatible with our injection–stratification hypothesis. We now return to the major event of the past 100 Myr, the Cretaceous–Tertiary boundary, to test further the compatibility of hypothesis and observation.

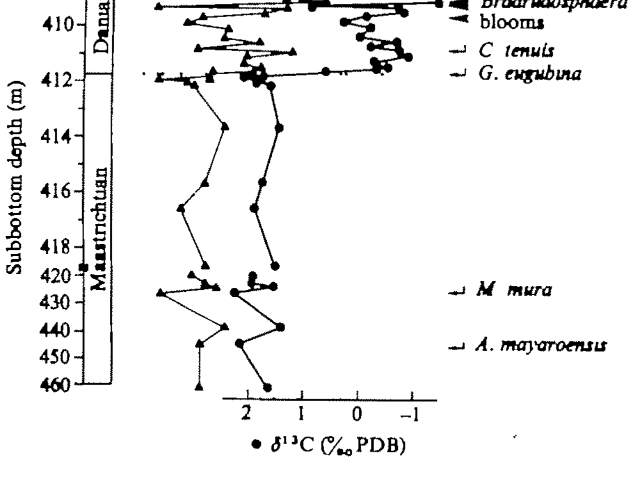
Cretaceous termination at site 356

Recent successes in drilling the deep-sea contact of the Cretaceous–Tertiary boundary[109,110] have made it possible to study in detail this major event in ocean history[14]. Here we present the first detailed stable isotope stratigraphy across the boundary. closely dated with coccoliths. Procedures and supporting material will be reported in more detail by H.R.T. *et al.*

The oxygen isotope and carbon isotope determinations shown (Fig. 2) were done on the fine fraction (<62 μm). We believe the record is continuous or nearly so, because it correlates well with that from Site 384, which has also been dated biostratigraphically in great detail[14]. In both sections the evolution of early Danian assemblages is characterised by an initial bloom of *Thoracosphaera* spp., with *Markalius astroporus*, *Zygodiscus sigmoides* and *Cruciplacolithus* spp. present, and by a subsequent bloom of *Braarudosphaera* spp. and dominance of *Cruciplacolithus* spp. In both sections the latest Cretaceous and particularly the earliest Danian nannoliths are well preserved[56,61]. It has been shown that in well preserved samples the stable isotopic variation of the nannofossil fraction parallels that of the planktonic foraminifera[111,114]. At Site 356 the uppermost Cretaceous oxygen and carbon isotope values are near −2.0‰ and +1.9‰ respectively, which are typical for Maastrichtian plankton elsewhere in low latitudes[81]. At the termination event both δ^{18}O and δ^{13}C values drop sharply within 40 cm. 'Warming' and the formation of a strong oxygen minimum are apparently indicated. The Danian coccolith flora is dominated by thoracosphaerids and baarudosphaerids, neither of which, however, exceeds 25% of the total fine fraction in any sample.

How can the sudden warming across the Cretaceous–Tertiary boundary be produced? In principle, a large amount of heat could conceivably be supplied from space (for example, by a solar flare) or from Earth's interior (for example, large outpourings of submarine lava). We find both hypotheses unattractive, although the evidence may be insufficient to reject them outright. According to the injection hypothesis, the warming has a strong signal of fresh water composition in it, which makes it unnecessary to search for an extraneous heat source. Lowered salinity readily explains both the demise of the tropical late Cretaceous forms and the bloom of typically coastal braarudosphaerids. The magnitude of the fresh water signal can be estimated very roughly. Assuming that the precipitation of water in high latitudes in the latest Cretaceous was tagged with the isotopic signal of today's mid-latitudes in the rainbelt[82] we obtain, say, $\delta^{18}O = -7‰$ for the fresh water injected from the Arctic. We take the average seawater δ^{18}O value as 0‰, for simplicity, and the salinity as 35‰. This yields a δ^{18}O of 0.2‰ for each 1‰ salinity change, when mixing fresh and saltwater. The excursion of δ^{18}O towards low values at termination time is −2.0‰, which translates into a lowering of salinity by 10‰, to 25‰, if the entire signal is due to mixing with fresh water. To the degree that warming occurs in the postulated stable surface layer, the salinity difference between normal and diluted seawater would be lessened. However, the difference must be increased to the degree that benthic mixing and the admixture of laterally transported Cretaceous nannoliths reduced the amplitude of the isotopic signal. We think that the estimate of a surface water salinity of 25‰ during the time of crisis is reasonable.

Fig. 2 Stable isotope curves of the fine fraction carbonate for DSDP Site 356, Sao Paolo Plateau, South Atlantic (analysis by John S. Killingley).



With the δ^{13}C signal, two effects must be considered. First, a marked decrease of plankton productivity would decrease the production of ^{12}C rich solids such as faecal pellets. The lack of removal of organics from surface waters would then decrease the carbon fractionation. Second, strong surficial stratification would result in the formation of a shallow, strong oxygen minimum. The effect of subsurface anaerobism on the δ^{13}C value in water can be estimated[112–114]. The relationship between the carbon isotopic composition of total dissolved carbon dioxide and the apparent oxygen utilisation (as calculated from Williams *et al.* (Fig. 2)[113]) is approximately $\Delta\delta^{13}C = -AOU/133$, where $\Delta\delta^{13}$C is in ‰ PDB − 1 and AOU is in μmol l^{-1}. For an initial content of about 200 μmol of oxygen l^{-1} in warm surface waters of normal salinity[115] and for total consumption, we get a signal of −1.5‰ in the δ^{13}C, all other factors being equal. This signal is too small to explain the observed change which is also muted by the considerable reworking of Cretaceous taxa. The injection hypothesis allows for a higher initial oxygen content due to reduced salinity and cooler (Arctic) water, by about 20–30%. Thus, a signal of about −2.0‰ is justified under the hypothesis. In addition, the demonstrated deviation from equilibrium of calcereous nannoliths towards lower $^{13}C/^{12}C$ ratios[114] may have been increased during post-termination time, due to sporadic bloom conditions, suggested by high abundances of thoracosphaerids and braarudosphaerids.

The rapid fluctuations in isotopic values in post-termination time seem to be real despite the somewhat wider sample spacing in the Upper Cretaceous. In part, such fluctuations can be produced by inhomogeneous benthic mixing, which has been observed at this boundary[109]. However, mixing can only scramble the frequency, and decrease but never increase the amplitudes of the signal. Thus, the impression remains that large fluctuations characterised post-termination time. This is also indicated by the sporadic blooms of *Thoracosphaera* ssp. and *Braarudosphaera* ssp.

At least two mechanisms exist for producing the fluctuations in the framework of the injection hypothesis: (1) repeated isolation and opening of the Arctic which led to repeated injection of freshwater; (2) climatic oscillations involving alteration of strong cooling and warming. Climatic oscillations could come from the effects of intermittent stratification on the CO_2 exchange of the ocean and the atmosphere[116]. Such oscillations together with decreased climatic equability would also have a profound effect on the survival of land animals[117]. It is interesting, in this context, to contemplate the extinctions of large land animals at the last injection event, the deglaciation some 12,000 yr ago[118].

We think that intermittent rapid addition to the world ocean of waters of unusual density produced in temporarily isolated basins in high and low latitude settings may account for some of the most puzzling oceanographic events discovered by deep-sea drilling, events which left their marks as mass-extinctions and widespread black shale deposits. Our hypothesis has implications for all Phanerozoic evolution, including the major mass extinction at the Permian–Triassic boundary.

We thank Professors A. G. Fischer, B. M. Funnell, A. Hallam and P. H. Roth for helpful suggestions. Sediment samples were obtained from the Deep Sea Drilling Project, which is sponsored by NSF. Research was supported by the NSF under grants nos. OCE76–22150 and OCE76–84029.

Do present levels of air pollution outdoors affect respiratory health?

Arend Bouhuys, Gerald J. Beck & Janet B. Schoenberg

Yale University Lung Research Center, New Haven, Connecticut 06510

A sensitive lung function test does not show differences due to air pollution between lifetime residents in a rural area and those in a small industrial town in Connecticut. Also, there is no evidence that higher air pollutant concentrations elsewhere have any marked effects on the lungs. Severe pollution is dangerous and must be avoided, but at present, air pollution control outdoors does not deserve priority as a means of preventing chronic lung diseases.

WE have assessed the impact of urban residence on respiratory health in the population of an industrial US town, in comparison with a rural population which included lifetime dwellers as well as migrants who had previously lived in cities. We determined differences in respiratory health between these populations from (1) the prevalence of common respiratory symptoms, and of bronchitis and asthma, and (2) lung function tests which reflect airway calibre. As air pollution outdoors is one 'urban factor' which may affect the health of people living in cities, we monitored several air pollutants at different sites in both towns.

The urban area had a record of high air pollution (by US standards) in the recent past, but the urban–rural pollution contrast at the time of our study was modest. We therefore also compared our results with data on people living in more severely polluted urban areas, and in other rural areas, so as to expand the pollution contrast.

To assess respiratory health in both towns, we used a questionnaire and a sensitive, standardised lung function test. We studied children and adults of both sexes, and healthy persons as well as those with respiratory symptoms or disease. Our population samples were large and representative of the total population of both areas. In analysing the results, we took into account sex, race, age, body height, body weight, smoking habits, occupation and previous residence. We believe that this is the first report of a study which combines all these features, and that it allows more reliable conclusions concerning urban factors and chronic respiratory disease (other than lung cancer) than do previous studies.

Populations and air pollution

The urban site, Ansonia, Connecticut, is an industrial town where mean annual particulate concentrations were among the highest measured in Connecticut during 1966–72 (88–152 $\mu g\ m^{-3}$; ref. 1); high SO_2 concentrations (by US standards) were probably also common in the past. In 1973, particulate concentrations were lower but still significantly higher than at the contrasting rural site, Lebanon, Connecticut. Lebanon is a sparsely populated town without factories or major highways, away from cities. Outdoor pollutants (Table 1) were monitored in both towns for more than 1 yr, including the period of our population surveys[1,2]. Concentrations of total suspended particulates (TSP; high-volume samplers) and of nitrogen dioxide were significantly higher at the urban sites, as were nitrates and sulphates (data in refs 1, 2). There were no significant differences for sulphur dioxide and ozone.

In two geographically defined areas (the town of Lebanon and the 4th Ward of Ansonia), we attempted to study all residents aged ≥ 7 yr. Response rates varied from 91–96% among boys and girls (7–14 yr) in both towns to 56% and 80% among 25–64-yr-old adults in Ansonia and Lebanon, respectively. From a private census and interviews of nonresponders[3], we concluded that the responders adequately represent the total populations. There were only 20 black residents of Lebanon; our main analyses are therefore limited to the white residents of Lebanon and Ansonia (Table 2). Of the Lebanon subjects, 41% had previously lived in urban areas; possible selection factors made it important to consider these subjects separately from lifetime rural (LR) dwellers. The few 'previous rural' (PR) Ansonia residents were excluded from analysis. Three smoking categories were considered: lifetime nonsmokers, ex-smokers of cigarettes, and current cigarette smokers (Table 2).

Questionnaire

We used an extended version of the MRC bronchitis questionnaire (for text, see ref. 4). Questions were prompted by computer and read by trained interviewers; answers were recorded in computer memory. There has thus been no omission or loss of data. Detailed written instruction and supervision of interviewers by the investigators promoted consistency in the interviews. We were unable to allocate subjects at random to interviewers, but an examination of symptom prevalences by interviewer showed that interviewer variation had no important effects on our results. Previous urban (PU) and lifetime rural residents of Lebanon were seen by the same interviewers; interviewer variation can be excluded as a cause of differences between these groups.

Chronic bronchitis

First, we examined the symptom complex of chronic bronchitis (usual cough and phlegm, more than 3 months per year for ≥ 2 yr). In groups of men and women by age (25+ yr) and smoking habits, smokers always had higher prevalences than nonsmokers or ex-smokers, but urban–rural differences were absent in all groups. For example, 19.0% of the rural male adult current smokers had chronic bronchitis, compared with 17.0% of their urban counterparts. Among both urban and rural residents aged ≥ 45 yr, the prevalence of chronic bronchitis was less than half that found (with identical methods) among active and retired textile workers at risk from occupational cotton dust exposure[5].

Asthma

A history of bronchial asthma ('yes' to the question: 'have you ever had bronchial asthma?') was more common among rural than among urban residents, regardless of age. The difference was highly significant for males (6.7% in 1,142 rural (=LR+PU) males; 2.6% in 458 urban males; $\chi^2 = 9.99$, $P < 0.01$) and similar differences, although not significant, persisted when only lifetime urban and rural residents were compared and when smoking was excluded by comparing only nonsmokers. Smoking habits were not significantly related to a history of bronchial asthma (χ^2 analysis).

Cough, phlegm and other symptoms

Chronic bronchitis may be an insensitive index of urban–rural differences because it is uncommon among nonsmokers. For its component symptoms, as well as wheezing and dyspnoea, we examined the relative importance of the residence variable and of sex, age and smoking habits in a weighted-least-squares analysis[6] of all data in 15–64-yr-old nonsmokers and current smokers. We omitted children, because few of them had any symptoms, and the elderly, because they were too few in number. We also excluded ex-smokers; their symptom prevalences were usually close to those of nonsmokers. Table 3 summarises the best-fitting models. Cigarette smoking was the only variable consistently associated with increased prevalence of all symptoms, at $P < 0.001$. For usual cough and phlegm, a linear residence variable (that is, LU > PU > LR) was highly significant among nonsmokers but not among smokers. The linear residence variable for dyspnoea was complicated by interactions between sex and smoking and between LU residence and smoking. The association between residence and dyspnoea was most pronounced among nonsmoking women (that is, 12.8% in 211 LR compared with 19.2% in 151 LU women). Among nonsmokers (men and women), LR residents had the lowest dyspnoea prevalence; among smoking men and

Table 1 The two towns and their air quality

	Lebanon (Rural)	Ansonia (Urban)
No. of inhabitants	3,800	21,200
No. of inhabitants per km^2	29	1,178
No. of dwellings per km^2	12	248
No. of vehicles per km^2	26	650
No. of commercial buildings and factories per km^2	0.03	17.8
Sulphur dioxide ($\mu g\ m^{-3}$)	10.9 ± 1.6 (41)	13.5 ± 1.7 (50)
Total suspended particulates ($\mu g\ m^{-3}$)	39.5 ± 4.2 (44)	63.1 ± 3.7 (50)
Nitrogen dioxide ($\mu g\ m^{-3}$)	55.5 ± 6.1 (41)	87.8 ± 4.9 (50)
Ozone ($\mu g\ m^{-3}$)	84.7 ± 4.4 (28)	88.5 ± 3.3 (35)

Demographic and geographical data from 1970 US Census, US Geological Survey maps, and municipal registries. Air pollutant data were obtained at 3–5 sites in Lebanon and at 4 sites in Ansonia, from January to December 1973, and are means ± s.e.m. of 24-h average concentrations, except for ozone values, which are means ± s.e.m. of peak 1-h concentrations (no. of observations in parentheses). Pollutant measurements (for methods and details, see refs 1, 2) were made with supervised, accurately calibrated samplers placed 120 cm above ground level, at least 16 m from any road and at least 11 m from physical obstructions (such as homes, trees). TSP and NO_2 were significantly ($P < 0.001$) higher in Ansonia than in Lebanon; SO_2 and O_3 did not differ significantly.

Table 2 Population groups by sex, age, residence and smoking habits

Residence		Age (yr)					Smoking			Total
Males		7–14	15–24	25–44	45–64	65+	NS	XS	S	
Lifetime rural (LR)		232	116	152	96	18	342	122	150	614
Previous urban (PU)		117	49	135	72	20	165	90	138	393
Lifetime urban (LU)		81	81	71	74	17	144	77	103	324
Previous rural (PR)		2	6	9	10	5	14	9	9	32
	Totals:	432	252	367	252	60	665	298	400	1,363
Females										
Lifetime rural (LR)		228	133	195	107	23	456	85	145	686
Previous urban (PU)		112	84	200	95	21	274	78	160	512
Lifetime urban (LU)		101	96	95	136	26	275	59	120	454
Previous rural (PR)		4	6	13	14	4	29	7	5	41
	Totals:	445	319	503	352	74	1,034	229	430	1,693

LR, lifetime residence in Lebanon and other rural areas; PU, current Lebanon rural resident but past residence in urban areas; LU and PR, lifetime urban and previous rural residents of Ansonia Total number of subjects (3,056) represents the total studied (3,387) minus 331 excluded for one or more of three reasons: (1) smokers of pipes or cigars only; (2) 1 yr or longer work in dusty occupations (mines, quarries, foundries, potteries, cotton mills, asbestos factories); (3) unclear history of previous residence (urban or rural) Lifetime nonsmokers (NS) had never smoked tobacco in any form; additional smoking of pipes or cigars by ex-smokers (XS) or current cigarette smokers (S) was not considered. Among children (7–14 yr) the number of ex-smokers and smokers was too small for analysis.

women the PU residents had the highest prevalence (30.8% compared with 21.5% in both LR and LU residents). Residence effects were less significant or absent for wheezing, and they were complicated by interactions with age. The significant age variables in Table 3 reflect higher prevalences among older than younger subjects, except for usual cough, where the 25–44-yr-olds had more symptoms than those who were younger or older. Sex was significant for usual phlegm, being more common among men, and for dyspnoea, which was more prevalent among women.

Figure 1 shows the observed prevalences of usual phlegm in relation to all variables which contribute significantly to its prevalence. There are no interactions, and the fit of the model is the best of all five in Table 3. Observed prevalences among women are similar to those predicted by the model. Among young urban male nonsmokers, the model seems to overpredict prevalence, but the difference between actual and predicted prevalence is not significant. All smokers, regardless of residence, have a higher prevalence of usual phlegm than do LU nonsmokers.

Lung function

We selected the maximum expiratory flow volume (MEFV) curve as a simple, sensitive and comprehensive lung function test[4]. It provides information on lung volume (forced expiratory vital capacity, FVC) as well as maximum expiratory flow rates. In previous studies, maximum flow at mid-vital capacity (MEF 50%) detected airway-constrictor effects of cigarette smoke[7], textile dust[8] and air pollutants[9] better than did measurements such as peak flow or forced expiratory volume in 1 s ($FEV_{1.0}$). We recorded MEFV curves on-line with a computer[10], calibrated every 2 h with a standard curve delivered by a mechanical device[11]. From data on healthy lifetime nonsmokers (by race, sex and age group) in three US communities, including Lebanon and Ansonia, we have derived regression equations for FVC, $FEV_{1.0}$, the $FEV_{1.0}$/FVC ratio, peak expiratory flow rate (PEF) and maximum flow rates at two other points on the MEFV curve (MEF50% and MEF25%), as a function of age, height and weight[12]. In the present study, these equations served to account for effects of age, height and weight in comparisons of lung

Table 3 Weighted least squares analysis of symptom prevalences

Symptom	Variables				Interactions			Fit of model	
	Smoking	Residence	Age	Sex	Age with	Smoking with.	LU residence with:	*P*	% Variation explained
Cough	+++	+++*	++	0	Sex +++			0.719	74.8
Phlegm	+++	+++*	+	+++				0.998	81.1
Recent wheeze	+++	+†	+	0	Smoking ++		Age +	0.759	79.7
Frequent wheeze	+++	0	0	0	Residence ++			0.962	67.4
Dyspnoea 1+	+++	+++‡	++	+++		Sex ++	Smoking +++	0.910	77.7

The table includes variables and interactions which contributed significantly to the explanation of the variation in symptom prevalence among all lifetime nonsmokers (NS) and current smokers (S) in Lebanon and Ansonia (age 15–64 yr). Logistic models always gave a better fit than did additive models. If x is the proportion of subjects with symptoms, the logistic model uses a logarithmic transformation of x, that is, $\ln[x/(1-x)]$, as the sum of effects of smoking, residence, age, sex and their interaction. Definition of symptoms: Cough and phlegm on most days for at least 3 months per year; recent wheeze, wheeze within past 12 months; frequent wheeze, wheeze at least a few times each week; dyspnoea 1+, dyspnoea when hurrying on level ground or walking uphill, or worse. Significance of variables and interactions· +++, $P\leqslant 0.001$; ++, $0.001< P\leqslant 0.01$; +, $0.01< P\leqslant 0.05$; 0, not significant. Explanation of interactions: Age × sex: difference between sexes (M > F) increases with age. Age × smoking: age increase of prevalence greater for NS than S. Age × residence: 25–64-yr-old PU residents more wheeze than LR and LU; 15–24-yr-olds lower prevalence regardless of residence. Smoking × sex: less effect of smoking in females than males; NS females have relatively high prevalence. LU residence × age: effect of residence on prevalence increase more pronounced in 25–44-yr-olds than in 15–24- and 45–64-yr-olds. LU residence × smoking· LU smokers have lower prevalence than LR and PU smokers; LU nonsmokers have higher prevalence than LR and PU nonsmokers.

* Linear residence variable significant within NS only.

† LR < PU = LU, $P = 0.045$.

‡ Linear residence variable significant for NS and S.

function between groups of subjects. These comparisons were based on calculations of lung function residuals, that is, the differences between observed and predicted values of each measurement.

Analysis of variance of lung function residuals (Fig. 2) among LR, PU and LU residents by sex, age and smoking habits showed no significant differences for any of the measurements. LR, PU and LU nonsmokers had similar residuals, none of which differed significantly from zero or from each other. Smoking adults, on the other hand, had significantly more negative residuals than comparable nonsmokers, regardless of residence. Inclusion of adults with occupational exposure hazards (see legend to Table 1 for definitions) gave results similar to those in the population which excluded these persons.

Susceptible groups

Urban air pollution might not affect all residents, but only unusually sensitive groups within the urban population. Our data suggest that, if such groups exist, they cannot be readily identified on the basis of age (in those aged ≥ 7 yr), sex, race or smoking habits. Attempts to identify susceptible subgroups from questionnaire data were equally unsuccessful. Among smokers, the amount smoked seemed to be the main variable, affecting both symptom prevalence and lung function (unpublished observations), and there were too few nonsmoking urban (LU) residents who reported a history of asthma to allow a comparison of the severity of asthma among urban and rural residents. Among residents with usual cough and phlegm, lung function losses were minimal and not significant either among rural (LR) or urban (LU) residents. Thus, although there may be small groups of persons sensitive to factors in the urban environment that do not affect most people, we have not been able to identify them.

The 'urban factor'

Studies in several US cities[13] have linked excess chronic bronchitis among smokers and nonsmokers to sulphur oxide and particulate pollution. In contrast, we have found that only lesser degrees of certain symptoms, not the composite syndrome of chronic bronchitis, may be associated with urban air pollution, and that this association only occurs in nonsmoking adults (age 15–64 yr; Table 3, Fig. 1). Among smokers, the influence of smoking overrides any differences associated with residence. However, the differences in symptom prevalences between urban and rural nonsmokers are not accompanied by differences in lung function. Even flows on MEFV curves (MEF50%; MEF25%), which are sensitive indices of airway obstruction[14], did not differ. Thus, we have no objective evidence for substantial differences in respiratory health between urban and rural residents.

Table 4 Lung function in nonsmoking California and Connecticut residents

	Los Angeles	San Diego	Connecticut		
			LU	PU	LR
O_3 ($\mu g\ m^{-3}$)	~300	~150	~100	~100	~100
TSP ($\mu g\ m^{-3}$)	124	78	65	42	42
No. subjects	90	135	73	41	56
Height (cm)	162	163	158	157	160
$FEV_{1.0}$ (l)	2.44	2.43	2.10	2.08	2.25
MEF50% ($l\ s^{-1}$)	3.38	3.37	2.96	2.81	3.09

Data for white, female, lifetime nonsmokers aged 45–64 yr. Los Angeles and San Diego data from Cohen *et al.*[28]. Data for males are similar. Higher lung function values in nonsmoking California women are explained by their height. All function values are close to those predicted for healthy nonsmoking adult white females[12].

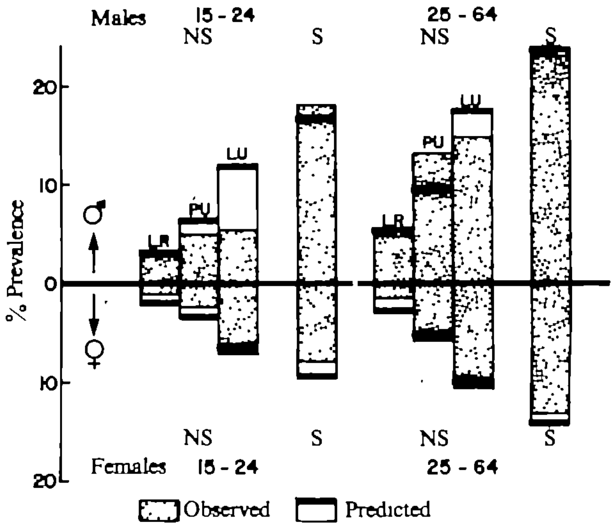
In the absence of lung function changes, what meaning should be attributed to the higher symptom prevalences among urban and previous urban nonsmokers? They might be due to trivial variables such as a different perception of questions by city and country people. The greater prevalence of dyspnoea among urban (LU) than rural (LR) nonsmoking women might be related to body weight (on average 4.1 kg more in 25–64-yr-old LU women than LR women). However, the LU–PU–LR gradient in prevalence of cough and phlegm among nonsmokers might reflect slight differences in respiratory health. For example, hypersecretion of bronchial mucus (leading to cough and phlegm production) may be more common among urban than rural nonsmokers. This disorder need not lead to progressive lung function loss[15]. It may be part of an adaptive mechanism (for example, increased mucus production may aid the clearance of pollutants) or it might represent incipient illness. Sputum from people in a polluted urban area may contain increased numbers of phagocytes and white cells[16]; these might secrete proteolytic enzymes which damage alveolar tissue[17], or they may protect lung tissue against inhaled particles, or both. No firm conclusion is possible, but the lack of function loss among our older symptomatic, lifetime nonsmoking urbanites suggests that the increased symptom prevalences are not associated with significant long-term deleterious effects on the lungs. Nor does our study indicate additive or synergistic effects between air pollution and smoking: lung function loss among smokers was similarly regardless of residence.

Our study cannot distinguish between air pollution and other urban factors as possible causes of the increased symptom prevalences among PU and LU nonsmokers. However, in a study designed to detect effects of air pollution peaks on daily symptoms among women in high- and low-pollution areas near Rotterdam, Wever[18] found significant associations, mostly in nonsmokers, of pollution peaks with cough, phlegm and dyspnoea, but rarely with wheezing. The similarity of Wever's findings to our own supports the assumption that in Ansonia, too, air pollution may be the 'urban factor' responsible for increased symptoms in lifetime urban nonsmokers.

Expanding the pollution contrast

We have examined the effects of greater air pollution contrasts than existed between Ansonia and Lebanon in three ways: (1) by considering health effects of high indoor pollutant levels in homes, (2) by comparing our findings with those of others, in areas with pollutant concentrations higher than those in Ansonia, (3) by examining respiratory health data from people living in clean rural areas.

Fig. 1 Per cent prevalence of usual phlegm by sex, age, smoking and residence (LR, PU and LU explained in Table 2). Predicted prevalences are those obtained from the model summarised in Table 3. Only significant variables are shown; for example, smokers were not subdivided according to residence as this variable was only significant among nonsmokers.



(1) Suspended particulates indoors are predominantly small-sized ($<1\ \mu m$ diameter) and thus able to penetrate into small bronchi and alveoli[19]. Hence, with equal TSP concentrations, indoor air might be more damaging to health than outdoor air, in which large particles are kept suspended by air currents. However, we found no evidence that the high TSP levels (up to $400\ \mu g\ m^{-3}$) in homes with smokers (ref. 20 and H. R. Hosein *et al.*, unpublished observations) were associated with increased symptoms or lung function loss among nonsmokers in the same homes. Nor did we find evidence for loss of lung function among children living in homes with parents who smoked[21]. Thus, much higher TSP concentrations than those which occurred outdoors in Ansonia may still be subthreshold with respect to health effects.

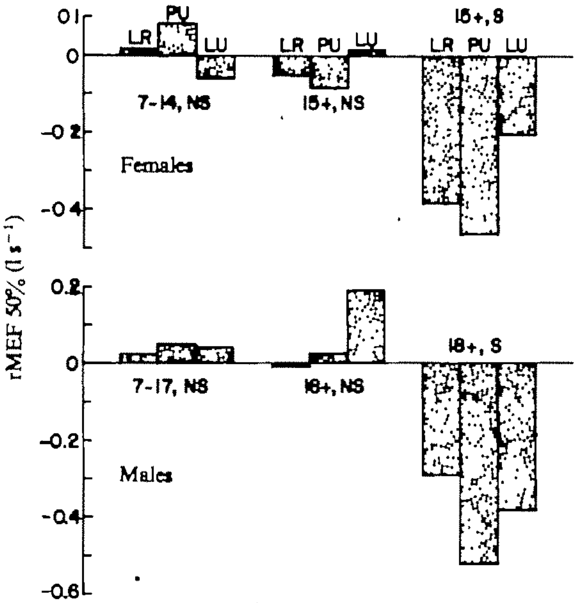


Fig. 2 Mean residual MEF50% (instantaneous maximum flow at 50% FVC). Residual (rMEF50%) = observed − predicted value. None of the differences between residential groups (LR, PU, LU, see Table 2) are significant in any of the six groups by sex, age and smoking habits. For boys and girls, this was also true when a further subdivision was made according to age (7–9 yr, 10–14 yr, 15–17 yr), and differences between LR, PU and LU residents were examined within each of these age and sex groupings. Differences between adult smokers and nonsmokers were significant within each residential subgroup (for example, LR smoking compared with nonsmoking males or females). For purposes of illustration, MEF50% is shown in $l\ s^{-1}$. The statistical analyses were, however, done on residuals in transformed units, ln MEF50% in children and $\sqrt{\mathrm{MEF50\%}}$ in adults; these transformations were required to obtain satisfactory prediction equations (see ref. 12 for the equations and their derivation). The equations with transformed units provide residuals which are normally distributed and have equal variances independent of age, height and weight within each subgroup by sex and age group. Values for s.e.m. residuals range over 0.037–0.085 in females and boys, and 0.1113–0.1755 in adult male groups. Differences between mean residuals in smoking groups may reflect differences in amounts smoked; although differences in amounts smoked were not significant between residential groups, PU men and women smoked more than LR and LU men and women.

(2) SO_2 and TSP concentrations have previously been high in many urban areas. In the UK, very high pollution levels (up to $1{,}160\ \mu g\ m^{-3}\ SO_2$) which occurred in 1965 and previous years, were clearly associated with exacerbations of bronchitis[22]. However, pollution levels lower than those in the UK in the 1950s and early 1960s do not seem to have any marked effect on health. For example, results similar to ours (a slight excess of cough and phlegm) were obtained among men employed in Manhattan in 1962–63 (ref. 23), before current air pollution control programmes began, and at a time when SO_2 and TSP were of the order of $500\ \mu g\ m^{-3}$ and $250\ \mu g\ m^{-3}$, respectively[13]. At about the same time (1961–62), nonsmoking black and white male postal or transit workers in New York City[24,25] had $FEV_{1.0}$ values almost identical to those in our urban and rural nonsmokers in 1973 when age, race and height are taken into account. According to our equations describing growth of lung function in children[12], Czech children (age 10–11 yr) living in a town with high SO_2 (annual mean $150–170\ \mu g\ m^{-3}$)[26] and TSP (annual mean $100–110\ \mu g\ m^{-3}$)[26] concentrations have lung function values[27] very close to those of 10–11-yr-old children in Ansonia and Lebanon.

Oxidant pollution has not been clearly linked with increased prevalence of chronic bronchitis or its component symptoms; in fact, chronic bronchitis seems to be about as uncommon among Los Angeles nonsmokers[28] as among our rural (LR+PU) nonsmokers of the same age (45–64 yr), that is, 1.7 and 1.5%, respectively. Nonsmokers in Los Angeles, exposed to higher oxidant and TSP concentrations, and nonsmokers in Connecticut have similar lung function when height is taken into account (Table 4).

(3) The lack of important contrasts in air pollution and respiratory health between Ansonia and Lebanon might be explained if Lebanon were a relatively polluted rural area. However, we have found no evidence that respiratory health is demonstrably better in pristine rural areas. Nonsmokers in such an area (Chilliwack, British Columbia) had higher prevalences of cough and phlegm[29] than our lifetime urban nonsmokers. Residents of Winnsboro, South Carolina (with significantly lower SO_2 and NO_2 concentrations than those of Lebanon[1]) had symptom prevalences and lung function similar to those of Lebanon residents, and a higher prevalence of a history of asthma (unpublished observations). Black children and adults in a primitive village in Upper Volta, away from cities and with minimal automotive traffic[30], had FVC and $FEV_{1.0}$ values similar to those we recorded among urban black residents in Ansonia and rural black residents in South Carolina.

We conclude from these comparisons between our data and those of others that even relatively low levels of air pollution (as in Ansonia) may be associated with a slight excess of some respiratory symptoms in nonsmokers, but that these symptoms may only become noticeably worse when SO_2 and particulates reach levels higher than those prevailing in Manhattan in 1962–63. Even high concentrations of SO_2, TSP and oxidants by current US standards are not associated with loss of lung function when sex, race, age, height and weight are adequately taken into account.

Implications

The overall impact of outdoor air pollution on respiratory health in Ansonia residents seems to be minimal. Even though the levels of air pollution in Ansonia are low by the standards of the UK in the 1950s, this is of interest because Connecticut is frequently said to have "the worst air pollution in the country outside Los Angeles" (ref. 31). However, any effect of air pollution in Ansonia is small compared with the effects of cigarette smoking and of certain occupational exposure hazards, such as occur among cotton textile workers[5]. Nor have we found evidence that outdoor air pollution worse than that in Ansonia (for example, in Los Angeles[28], New York[23,24,25], Rotterdam[18] or Czechoslovakia[26,27]) produces substantially greater effects on health. Our conclusions are valid for those lung disorders which affect vital capacity and air flow rates; these include asthma, bronchitis and emphysema. There may be sensitive subgroups within the general population which we have not been able to detect, but this remains speculation.

The extent to which communities want to abate air pollution, and the economical burdens which they are willing to accept for that purpose, are matters for society to decide. There are many reasons, aesthetic as well as hygiene-related, for reducing urban air pollution. Within rather wide margins, however, variations in air quality do not seem to have substantial effects on the prevalence and severity of common diseases which affect airway calibre.

Molecular structure of a double helical DNA fragment intercalator complex between deoxy CpG and a terpyridine platinum compound

Andrew H. J. Wang*, Jeremy Nathans*, G. van der Marel†, J. H. van Boom† & Alexander Rich*

The crystal structure of a complex containing deoxy CpG and a terpyridine platinum compound (TPH) shows a DNA double helical fragment with TPH intercalated between two Watson–Crick GC base pairs. The DNA unwinding angle is 23° and the pucker of the deoxyribose rings differ at the 3' and 5' ends.

STUDY of the molecular structure of nucleic acid components is of considerable interest in developing an understanding of the macromolecular nucleic acids. Single crystal X-ray diffraction analysis allows us to determine unambiguously several geometrical details concerning these molecules. Studies from this laboratory[1–4] showed that it was possible to crystallise self-complementary ribodinucleoside phosphates as double helical fragments with Watson–Crick hydrogen bonding between the bases. An interesting application of these studies is their extension to double helical fragments which crystallise with planar molecules intercalated between their base pairs. Lerman[5] postulated that certain classes of planar molecules, many of which are mutagenic or carcinogenic, act by insertion between adjacent base pairs in the DNA double helix. Several structural studies have supported this interpretation. Sobell and his colleagues[6,7] described the structure of an RNA double helical fragment which contained an intercalator and several different structures of this type have now been solved with a variety of intercalators lodged inside double helical ribonucleotide fragments[8–11]. These crystallographic studies show that the pucker of the ribose ring is modified by the insertion of an intercalator between the base pairs. However, a major difference between DNA and RNA double helices is the different pucker of the sugar ring. It is therefore of interest to ask how intercalation will modify the geometry of the DNA backbone especially with regard to the pucker of the deoxyribose ring[12].

In this article we report the crystal structure of a complex containing deoxycytidylyl-(3',5')-deoxyguanosine (deoxy CpG) which has crystallised with the intercalator 2-hydroxyethanethiolato-2,2',2''-terpyridine-platinum (II) [TPH][13,14]. In this structure, deoxy CpG forms an antiparallel double helix in which the helix has unwound and the base pairs are unstacked with one TPH molecule intercalated between the base pairs of the double helical fragment. Another TPH molecule is stacked between double helical fragments in the lattice. This structure allows us to determine directly both the unwinding angle of the DNA double helical fragment as well as the pucker of the deoxyribose rings.

Experimental methods

The dimer deoxy CpG was prepared using the phosphotriester method[15,16]. The dimer thus obtained was converted into the ammonium salt by passing it twice over a Dowex cation-exchange resin in the NH_4^+ form. The material was freeze dried

0028–0836/78/0276—0471$01.00

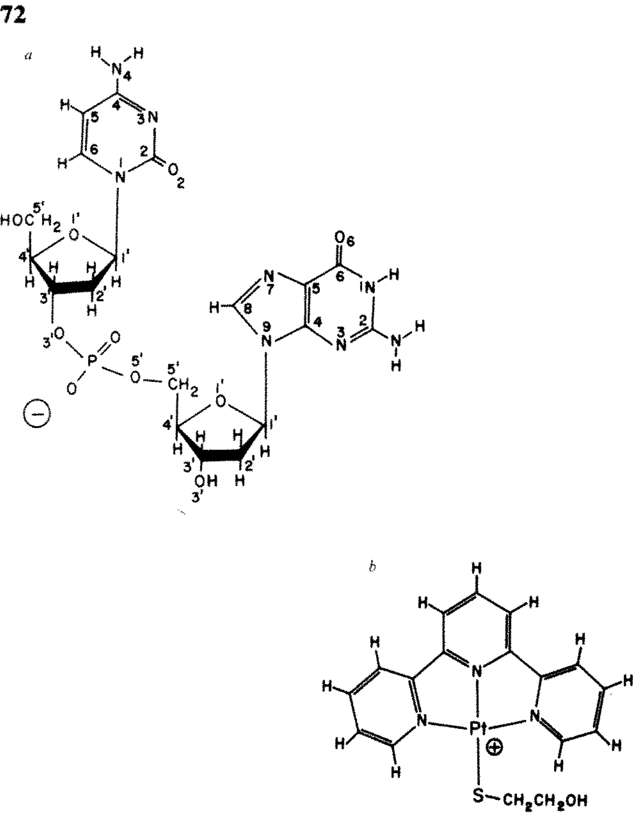

Fig. 1 Structural formulae of *a*, deoxycytidylyl-(3′,5′)-deoxyguanosine and *b*, TPH.

to a fluffy solid. The product was homogeneous and contained 3′–5′ internucleotide linkages only (as shown using high pressure liquid chromatographic analysis and enzymatic digestion by spleen and venom phosphodiesterases). The intercalator TPH was prepared as described by Lippard and his colleagues[13,14].

Crystals were grown using the vapour diffusion method at room temperature in a manner similar to that used in crystallising tRNA[17]. An aliquot of 80 μl of an aqueous solution containing 3mM NH_4^+ deoxy CpG, 3mM of the intercalator TPH nitrate, 25mM sodium cacodylate buffer (*p*H 6.0), and 17.5% 2-methyl-2,4-pentanediol was placed into a depression of a spot plate. The plate was sealed in a small chamber over a reservoir solution containing 75% 2-methyl-2,4-pentanediol. Orange-red plate crystals were obtained within 1 week. The UV spectra of dissolved crystals indicated a one-to-one stoichiometry of both the intercalator and the nucleotide. The material crystallised in the space group $P2_12_12_1$ with $a = 22.25$ Å, $b = 13.57$ Å, and $c = 33.12$ Å. Examination of precession photographs showed very strong reflections at 040 and 020 which correspond to planes at intervals of 3.4 and 6.8 Å along the *b* axis. This suggested stacking of base and intercalator planes perpendicular to the *b* axis which was verified by the structure determination. Data were collected at 8 °C with Ni-filtered CuK_α X-ray radiation on a Picker FACS-I diffractometer to a resolution of 1.1 Å. 3,519 independent reflections were measured with intensities greater than two standard deviations over their background. Data were corrected for Lorentz and polarisation factors as well as for absorption. A Patterson map revealed the position of two platinum peaks—one sharp and one moderately disordered. The structure was determined by difference Fouriers ($F_o - F_c$) and sum function Fouriers ($2F_o - F_c$) and was then refined by the least-squares method in successive cycles using a PDP 11-50 computer. The Nonius structure determination package was used. At the present stage of the refinement, the residual factor (R-factor) has been reduced to 15%. In addition to locating the intercalators and nucleotides, 20 water molecules have been identified in the asymmetric unit.

Results

Figure 1 shows the structural formulae of deoxy CpG and the intercalator TPH—singly charged molecules of opposite sign. The 2:2 complex is thus electrically neutral and no other ions are found in the lattice. Figure 2 shows a view of the molecule looking down the *a* axis in which the planar intercalator and base pairs are visualised virtually end on. In this view, it can be seen that the guanine and cytosine bases are paired together with three hydrogen bonds as is generally assumed to occur in DNA. The TPH in the centre of the diagram is intercalated between the two base pairs in the double helical fragment. The deoxyguanosine at the 3′ end of the molecule has a deoxyribose with the C2′ *endo* pucker, which is the normal pucker found in double helical B DNA[18]. However, the deoxycytidine at the 5′ end has a modified pucker, namely C3′ *endo* which is usually found in double helical RNA[19] but is not found in normal B DNA. At the top and the bottom of the diagram are two intercalator molecules which are located at either end of the small double helical DNA fragment. These are related by a unit cell translation along the *b* axis, and are moderately disordered in the plane of the molecule. They are found principally in two locations, approximately 3.2 Å apart, located on either side of the pseudo-2-fold axis which is found parallel to the *a* axis at this level. The two sites occupied by this TPH molecule have nearly equal occupancies. Because of this disorder, the hydroxy-ethyl side chains of these stacking TPH molecules are not shown in Fig. 2. The complex has a non-crystallographic pseudo 2-fold axis passing through the intercalated TPH molecule parallel to the *a* axis. The hydroxy-ethyl side chain which is attached to the central intercalating TPH molecule effectively prevents the existence of an exact 2-fold axis at that point since the side chain does not have 2-fold symmetry as seen in Fig. 2.

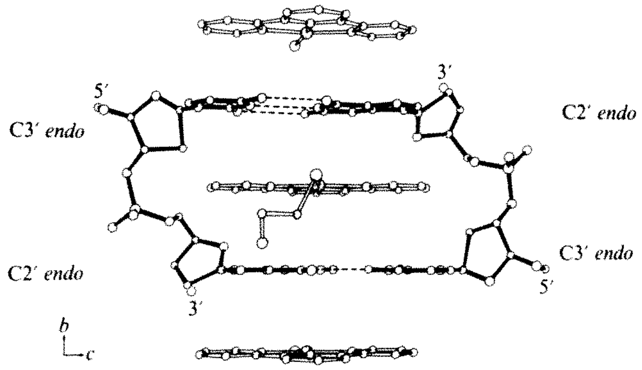

Fig. 2 View of the structure as seen down the *a* axis. The hydroxyethane side chains are not shown for the intercalators at either end of the double helical fragment. The glycosidic torsion angle (χ) is seen to be different at the two ends of the deoxy CpG. The two deoxyguanosine torsion angles are 114° and 117°; the angles for deoxycytidine are 32° and 34°. The phosphodiester linkage has a *gauche-gauche* conformation. Oxygen, sulphur, phosphorus and platinum atoms are drawn with larger circles than carbon atoms; the platinum atoms are stippled. Hydrogen bonds are drawn as dashed lines.

Figure 3 is a diagram of the double helical DNA fragment containing the intercalating TPH molecule. This is a view perpendicular to the base pairs and the central intercalator. The difference in the pucker of the deoxyribose rings at the 5′ and 3′ ends of the molecule can be seen. It also shows the extensive overlapping of the π electron systems of the purine and pyrimidine rings with the terpyridine of the intercalator. Interestingly, all of the double helical ribodinucleoside phosphate intercalator structures which have been crystallised also contain the intercalator inserted in a pyrimidine–purine sequence[6-11]. In

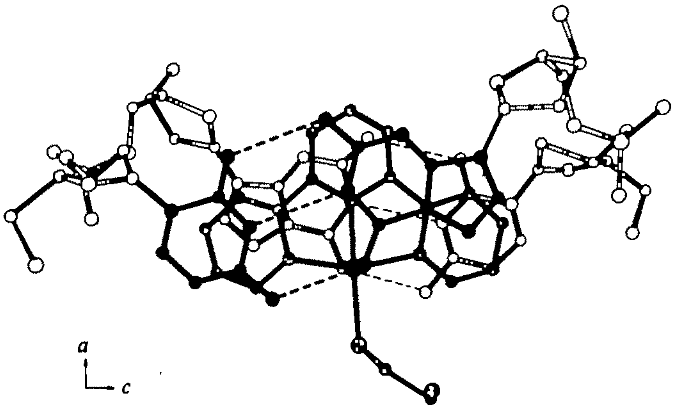

Fig. 3 A view of the structure down the *b* axis. Only the central intercalated TPH molecule is shown with the double helical fragment. The base pair closest to the reader is shaded solid black, the central intercalator is stippled while the bottom base pair is unshaded. The difference in deoxyribose pucker at the two ends of the chain is shown clearly here. Considerable overlap is evident between the bases and the intercalator pyridine rings. A pseudo-2-fold axis can be seen along the sulphur–platinum bond.

the native double helix there is less base stacking at the sequence pyrimidine–purine than at the sequence purine–pyrimidine. The stacking in the present pyrimidine–purine structure is considerably enhanced by the insertion of the intercalator, as seen in Fig. 3. For example, the outer pyridine rings are in a position where they provide a considerable degree of overlap for the purine ring on one side and the pyrimidine on the other. In a similar way the central pyridine ring of the intercalator overlaps the two purine residues in the centre of the molecule. Note that the oxygen O6 of both guanine molecules are located virtually above and below the central platinum atom in the intercalator, 3.4 Å away. It remains to be seen whether this feature plays a part in the interaction between this intercalator and the base pairs. It should be noted that the three unsaturated pyridine rings are organised in an arc which effectively overlaps the base pairs above and below. A similar arc-like arrangement is found in several of the unsaturated condensed ring intercalators such as ethidium and ellipticine$^{6-9}$. As is shown in Figs 2 and 3, the side chain of the intercalating molecule is located in the major groove of the double helix. This orientation is in contrast to the TPH molecules which are stacked at either end of the double helical fragment. Here the side chain is located on the opposite side close to the narrow groove of the double helical fragment.

It can be seen in Fig. 3 that the TPH is intercalating in a symmetrical manner in this complex which is quite different from that which is seen in the ribonucleotide intercalation structures containing acridine orange, 9-aminoacridine and ellipticine^{9,11}.

The intercalator–double helical fragments are stabilised in the crystal lattice by a number of intermolecular interactions. These include hydrogen bonds from the hydroxyl group of the TPH intercalator to the cytosine O2 of another complex. There are also hydrogen bonds between the C5′ OH of deoxycytidine to phosphate oxygens of an adjoining molecule which is related to it by twofold screw axes along the *c* axis. In addition, O3′ of the deoxyguanosine residue is hydrogen bonded to O2 of the cytosine in an adjoining molecule. There are a number of water molecules which form both intramolecular and intermolecular hydrogen bonding bridges. An interesting intramolecular bridging hydrogen bonded water molecule is found connecting the C5′ hydroxyl group and the phosphate oxygen of the same polynucleotide chain. This is responsible for the conformation of the C5′ terminus of the oligonucleotide. However, this bridging water molecule is not likely to be present when the DNA is present in a normal double helical conformation.

It can be seen in Fig. 3 that the two GC Watson–Crick base pairs are related to each other by a right-handed helical rotation. In the B form of DNA the vector between the C1′ atoms of the deoxyribose residues of the hydrogen bonded base pair are related to that of the next base pair by a rotation of 36°, as there are 10 base pairs per turn of the helix. In the present structure, however, the base pairs are no longer 3.4 Å apart but rather 6.8 Å apart due to the intercalator separating them. The inter-strand C1′–C1′ vector is related to the corresponding vector on the other side of the intercalator by an angle of 13°. Thus there is an unwinding of the double helix of 23° relative to that which it would normally have in the absence of the intercalator.

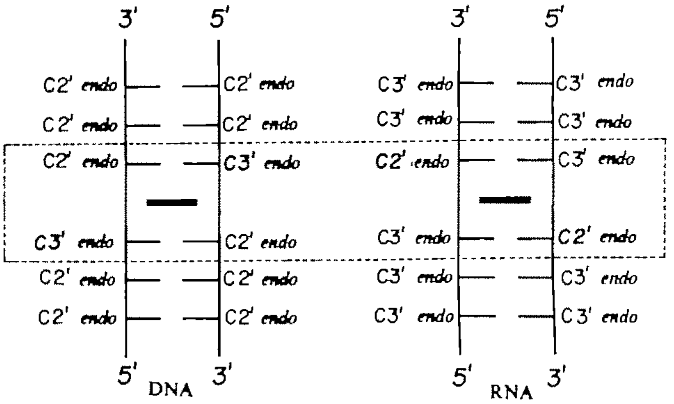

Fig. 4 A schematic diagram showing the sugar conformation in double helical DNA and RNA. The DNA is in the normal B form. The conformational effects of an intercalator are illustrated in the dashed region where the changes in sugar pucker are shown in bold face. For simple intercalators, the conformation in the dashed region is the same for the DNA and the RNA double helix.

Discussion

The intercalator used in this study has several experimental advantages. The presence of the unsaturated terpyridine rings provide a substantial degree of overlap with the adjacent purines and pyrimidines. In addition, the centrally coordinated platinum atom significantly facilitates solution of the X-ray diffraction problem. This intercalator has been used extensively by Lippard and his colleagues in a variety of studies as reviewed recently^{20}. Intercalators of this type compete with ethidium and induce viscometric and spectroscopic changes which can be readily interpreted as due to interaction with DNA in an intercalative mode.

This crystal structure shows the manner in which the DNA double helical fragment accomodates the interposition of a planar molecule between the base pairs. In view of the extensive previous work with intercalators in fragments of an RNA double helix (Table 1), we can make a comparative study. The important difference between the DNA and the RNA double helix is the presence of the additional 2′ OH group in the ribose of RNA, which makes RNA adopt a C3′ *endo* ring pucker while in DNA the deoxyribose is normally C2′ *endo*^{18,19}. This nomenclature refers to the displacement of either the C2′ or C3′ carbon atom out of the plane of the ring in a direction towards the base or the major groove of the double helix. One of the features of several RNA double helix–intercalator structures (Table 1) has been the observation that puckering of the ribose rings differs at the 3′ and 5′ ends of the intercalated segment. This is especially true with 'simple' intercalators which do not form hydrogen bonds with the nucleotide backbone. The same phenomenon is seen in the present structure. The DNA fragment shows a C3′

Table 1 Intercalation geometry of nucleic acid structures*

	Dinucleoside phosphate	Intercalator	Sugar pucker 5′ end	Sugar pucker 3′ end	Twist angle	Ref.
DNA fragments	dCpG	TPH$^+$	C3′ *endo*	C2′ *endo*	13°	This work
RNA fragments	rIodoUpA	Ethidium$^+$	C3′ *endo*	C2′ *endo*	8°	6, 7

	rIodoCpG	Acridine Orange$^+$	C3′ *endo*	C2′ *endo*	10°	11
	rIodoCpG	Proflavine$^+$	C3′ *endo*	C3′ *endo*	36°	11
	rCpG	Proflavine$^+$	C3′ *endo*	C3′ *endo*	33°	10

* Two different classes of intercalators are indicated by the dashed line.

endo conformation at the 5′ end of the dinucleoside phosphate and the normal C2′ *endo* conformation at the 3′ end, that is C3′ *endo* (3′, 5′) C2′ *endo* mixed sugar puckering. In the simple intercalated RNA helical fragments it is the 3′ end of the ribonucleotide chain which is perturbed to adopt the C2′ *endo* conformation which is normally found in the B form of DNA but not normally found in the double helical RNA chain. There are two interesting exceptions which occur with proflavine intercalation as shown in Table 1. These differences are likely to be associated with the fact that the amino groups on proflavine form hydrogen bonds with the phosphate group of the internucleotide link. This may have the effect of constraining the pucker which the ribose residues can adopt.

For the class of 'simple' intercalators which intercalate but do not hydrogen bond with the phosphate groups we see an interesting similarity in the manner in which the DNA double helix and the RNA double helix accomodate the intercalation (Fig. 4). Away from the intercalated site, the sugars of the two types of double helices have the different puckers mentioned above. At the intercalator site (Fig. 4) both polynucleotide chains have a similar C3′ *endo* (3′,5′) C2′ *endo* conformation. This result supports the use of intercalated RNA helical fragments as models for studying the geometry of DNA intercalation. Such a mixed puckering conformation has also been suggested to occur in B DNA by a model building study[21]. This identity of conformation in the region surrounding the intercalators is due to a change in the conformation of the DNA segment at the 5′ end of the internucleotide linkage surrounding the intercalator moving towards the conformation found in the RNA double helix. In the RNA double helix, a new conformation is adopted at the 3′ end, the C2′ *endo*, which is normally associated with the DNA double helix. The net effect of both of these changes is that it gives rise to the familiar nearest-neighbour exclusion effect which is found with intercalation. When double helical DNA or RNA is fully saturated with intercalators, only every other site can be occupied. This is because the conformational change adopted by the polynucleotide chain in accomodating the intercalator differs at the 3′ and 5′ end. One cannot obtain this conformation between every base pair but at best between every other base pair. An X-ray diffraction study of DNA fibres using the same terpyridine platinum complex used in this study demonstrated the nearest-neighbour exclusion in DNA fibres[22]. The interpretation was facilitated by the presence of platinum in the intercalator which scatters X rays strongly.

One of the features associated with intercalation in a DNA double helix is the fact that it gradually unwinds the helix. Studies of ethidium intercalation into supercoiled DNA has made possible a calculation of the unwinding angle in DNA associated with each molecule of ethidium[23]. The studies indicate that insertion of ethidium between the base pair decreases the twist angle between the base pairs by 26° ± 2°. This value is very close to the 23° observed in the present structure and is also similar to the results seen with the insertion of simple intercalators into ribonucleotide fragments. In contrast, the intercalator proflavine which hydrogen bonds to the phosphate groups has an unwinding angle of 0°.

In the present crystal structure one of the TPH molecules is used to maintain continuity of stacking between one double helical fragment and the next. That molecule is disordered in an interesting manner. In one of the two disordered positions, there is a maximum degree of overlap with the guanine residue in the double helical fragment below it. In the other disordered position, there is a greater degree of overlap with a guanine residue from the double helical fragment above it. One element in the disordering process may be due to the presence of two positions with similar energy minima. There is no disorder in the intercalated TPH molecule.

Single crystal analyses of nucleic acid fragments have considerable value in providing us with fine details associated with the manner in which these molecules adapt to a variety of environments. The present investigation has illustrated the manner in which the DNA backbone accomodates the insertion of an intercalator between base pairs. Studies similar to these, and especially those involving longer deoxyoligonucleotides should prove of great value in enhancing our understanding of the mode of action of DNA in biological systems.

We thank Professor S. Lippard for terpyridine platinum intercalators and Dr J. Sherfinski for assistance. This research was supported by grants from the NIH, NSF, NASA, the American Cancer Society and the Netherlands Foundation for Chemical Research (SON). Pulsed and unpulsed light from the Vela and Crab pulsars

OBSERVATIONS of the Vela and Crab pulsars were made with the Image Photon Counting System[1] (IPCS) at the *f*/15 focus of the 3.9 m Anglo–Australian Telescope (AAT), on 9 and 10 March 1978. Observations of the unpulsed light from the Crab pulsar have been obtained with an electronographic camera[5] used with the 0.9 m Yapp reflector of the Royal Greenwich Observatory (RGO). We obtained phase-resolved pictures of the Vela pulsar[2,3], positively identifying it with the faint, blue candidate star[4] and detecting a relatively strong, unpulsed light component. We also detected a weak unpulsed component from the Crab pulsar.

In the AAT observations the pulsar period was divided into eight phase intervals, and a picture was accumulated of the area around the pulsar during each phase interval. The eight pictures, each of 42×42 pixels (corresponding to 12 arc s on a side), were held in the memory of an Interdata-70 computer. Every millisecond, an interrupt from the observatory timing system caused the computer to calculate the current phase of the pulsar, and select to which of the eight pictures the next TV frame from the IPCS would be delivered. In this way, TV frames from the IPCS, generated every 6.2 ms, were stored and each picture in the computer memory became the integration of many frames from the same phase interval. Total integration times on the Vela pulsar were respectively 5 h 16 min (B) and 3 h 30 min (U). Crab pulsar observations were for ~10 min each with the telescope stopped down to 1.8 m aperture (central obstruction of secondary 1.4 m); this was to prevent saturation of the IPCS during the bright portion of the pulse. The Vela pulsar observations were all phased with respect to the dedispersed radio pulse arrival time, 21 ms before the first optical pulse. Predictions of radio pulse phase were made from radio measurements made as part of a continuing series of pulsar timing observations[6]. The Crab pulsar observations were obtained at arbitrary phases.

During the observations, the eight phase-resolved pictures were cyclically displayed on a TV monitor, so that the pulsar pulses were seen in stroboscopic fashion. Photographs of the display are shown in Fig. 1 for observations in blue light (B-band) for the Vela and Crab pulsars. Figure 1 confirms the identification[3] of the Vela pulsar with the star known[4] as M and clearly shows residual emission in its light curve outside the two main peaks, which fall in phases 2 and 4.

The intensities of stars in each field observed with the IPCS were determined by a least squares procedure which simultaneously fitted the sky background (three parameters), the positions and intensities of the stars (three parameters per star), and the stars' profile expressed as a two-dimensional semi-empirical point-spread function with central core and extended wings (five parameters). Nebulosity in both the Crab and Vela pulsar fields could produce systematic errors in the measurements of the pulsar intensities, and so was determined from the data by an iterative technique. The residuals resulting from an initial fit were smoothed by a broad spatial filter to determine the background variations whose scale was large, compared to the size of a star, but which was small compared to the size of the field. This picture, representing the background nebulosity, was subtracted from the picture of the pulsar field, and the star intensities were obtained by reapplying our fitting procedure. The intensities of the Crab and Vela pulsars in the B and U filter bands are given as a function of pulse phase in Fig. 2.

A surprising result from the observations is the intensity of the emission from the Vela pulsar outside the two main peaks. The unpulsed emission accounts for about half the total emission from the pulsar. To estimate the intensity of the unpulsed light we have fitted higher resolution light curves to the data in the following way.

Each of the pictures within a set of eight covers an interval of pulsar phase. The edges of this interval are blurred by the IPCS response time and by the millisecond timing interrupts. Thus the pulsar intensities derived from those pictures which give the lowest intensities may include pulsed light from adjacent phase intervals in which the pulsars were brighter. This problem is severe in the case of the Crab (period 33 mins, phase interval 4 ms) but not as severe for Vela (period 89 ms, phase interval 11 ms). Light curves obtained in 1977 with an unfiltered S20 photomultiplier and high time resolution[3] have been convolved with the appropriate smoothing function representing the instrumental smearing. Assuming that the shape of the light curve is unchanged in the past year and that the shape of the pulsed component does not depend much on the colour in which it is observed, we fitted the amplitude and baseline of the convolved light curve by a least squares procedure to the pulsar intensity derived from the IPCS observations. The fit of the convolved light curves to the observations is shown in Fig. 2*a*. The high time resolution light curves used for the convolution are plotted in Fig. 2*b*; for each curve the true zero is represented by the base of the plot.

The apparent magnitudes in U and B of the time averaged

Table 1 Pulsar magnitudes

	Crab	Vela
Mean apparent magnitude (B)	—	23.56 ± 0.03
Mean pulsed apparent magnitude (B)	17.0*	24.4
Mean steady apparent magnitude (B)	18.6	24.3
Mean apparent magnitude (U)	—	23.20 ± 0.14
Mean pulsed apparent magnitude (U)	16.5*	23.8
Mean steady apparent magnitude (U)	18.1	24.2
Distance[11] (pc)	2,000	500
Distance modulus (m–M)	11.5	8.5
Absorption[3,12] (A_B)	2.1	0.5
Absorption[3,12] (A_U)	2 8	0.7
Mean steady absolute magnitude (M_B)	5.0	15.3
Mean steady absolute magnitude (M_U)	3.8	15.0
Ratio of steady/pulsed light expressed as a difference in magnitude (B)	1.6	−0.1
Ratio of steady/pulsed light expressed as a difference in magnitude (U)	1.5	0.4

intensity from the Vela pulsar are given in Table 1. Calibration of the blue sensitivity of the IPCS was with respect to faint standard stars in the globular cluster ω Centauri (R. Cannon, personal communication), and the standard error quoted for the blue magnitude represents the internal consistency of the data, as the calibration is relatively well assured. Calibration of the UV sensitivity of the IPCS was with respect to star K (ref. 3) and with respect to UV measurements[7] of brighter stars in ω Cen (no faint U standards are available). The brighter stars were observed with the telescope out of focus in an attempt to avoid saturation problems of the IPCS. Because this calibration is less assured, a larger standard error for the U measurement is given based on the agreement within the methods.

Table 1 also gives estimates of the magnitudes of the pulsed and unpulsed light from each pulsar. The model chosen to distinguish pulsed and unpulsed light is that the high-resolution light curves representing the pulsed emission are supported on a steady pedestal of constant emission.

The presence of the small unpulsed background from the Crab pulsar, which amounts to 3.6 ± 0.7% of the peak intensity

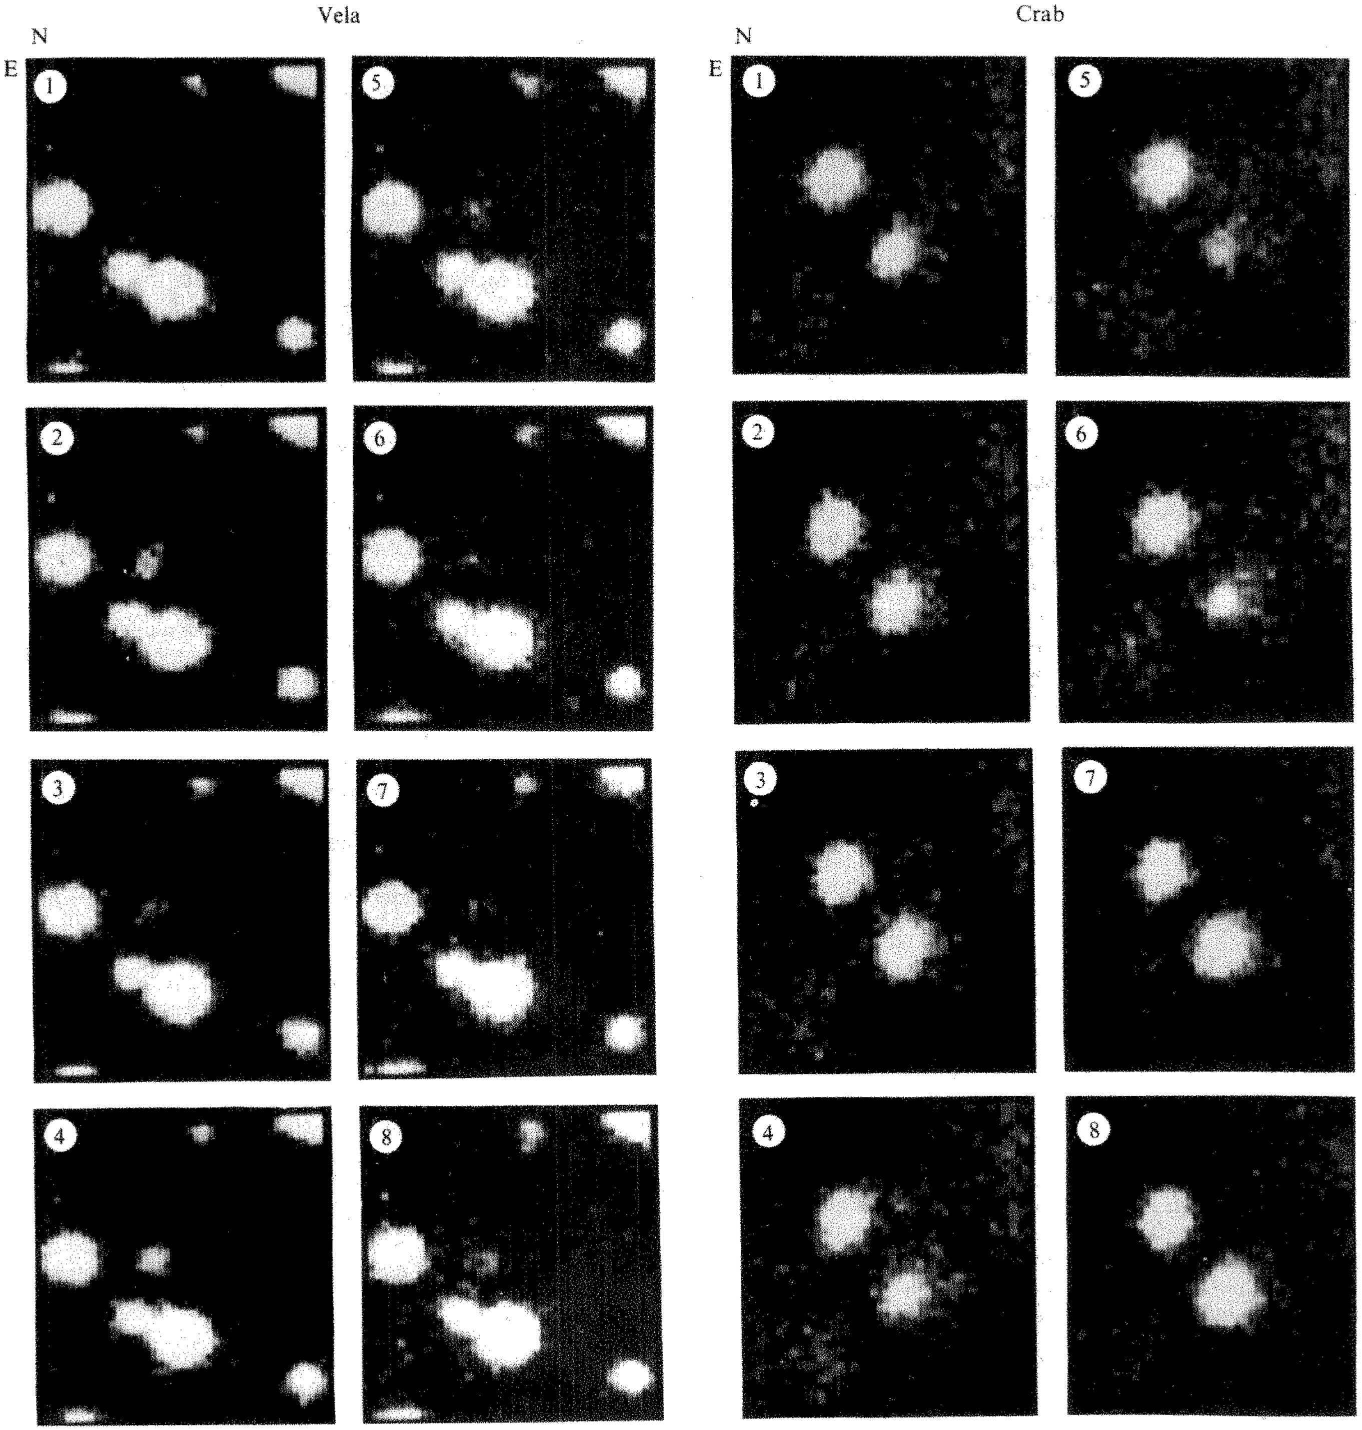

Fig. 1 The fields of the Crab and Vela pulsars in blue light as shown by the observing display at the Anglo-Australian Telescope. Each field covers an area on the sky 12 × 12 arc s, and one eighth of the phase of the pulsar's cycle. The fields are numbered in sequential phase order for each pulsar. The main pulse of the Crab pulsar occurs in phases 7 and 8, while the inter-pulse occurs in phases 2 and 3. The main double pulse of the Vela pulsar occurs in phases 2 and 4. Emission can be seen throughout the whole cycle of the Vela pulsar. (Emission seen throughout the whole cycle of the Crab predominantly results from instrumental smearing.)

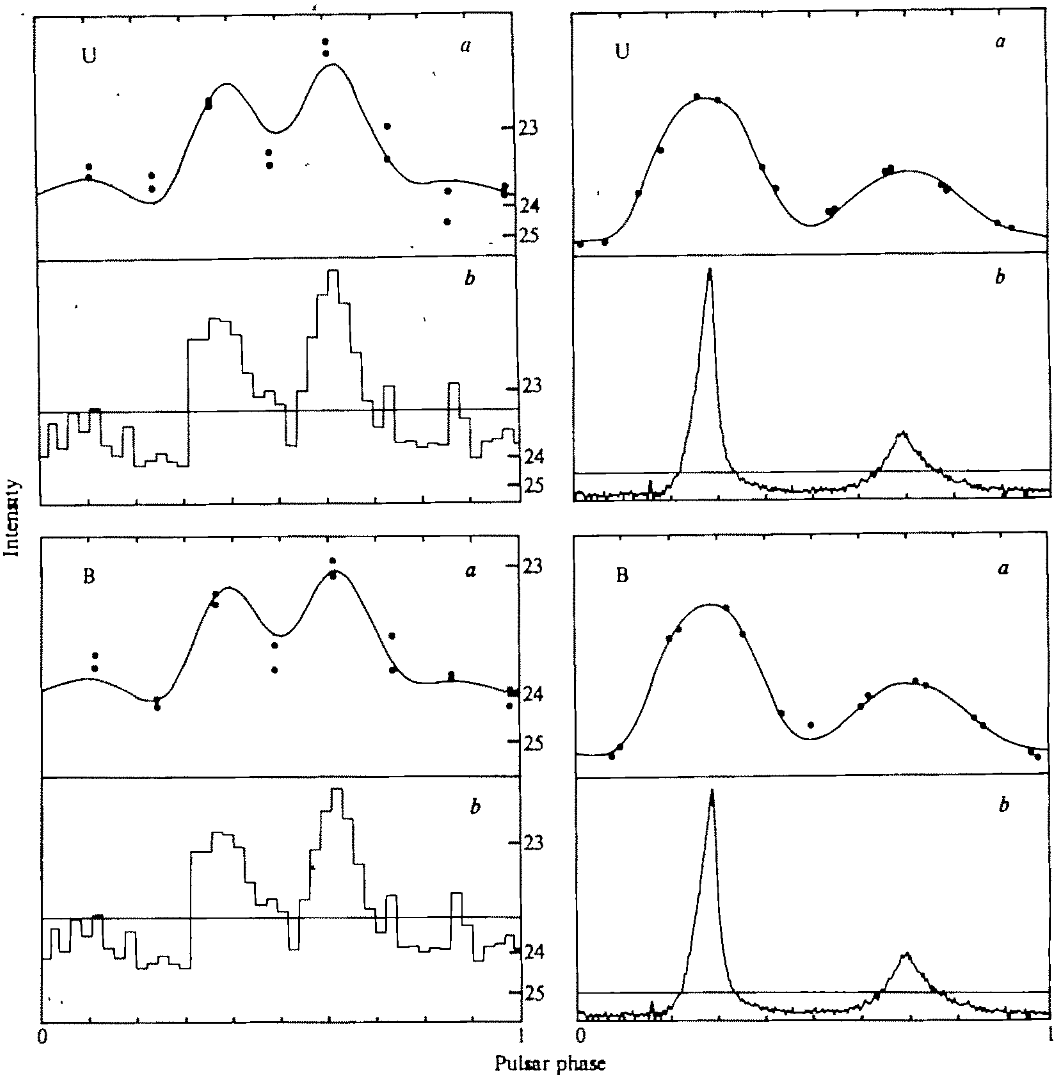

Fig. 2 Light curves of the Crab and Vela pulsars in UV (U) and blue (B) light. Points represent the intensity of the pulsars as observed with the IPCS. (The data were divided into halves of equal weight to generate two points per phase interval.) As described in the text, curves were fitted to the data points by smoothing high-time-resolution profiles obtained with unfiltered S20 photomultipliers in earlier observations[2]. The high-time-resolution profiles are shown in the lower panels (*b*) with their mean intensity indicated by the horizontal line. In all eight panels of this figure, the ordinate represents light intensity correctly zeroed at the base of each panel. Calibration to magnitudes is given on the right hand ordinate, for the Vela pulsar. The abscissa of each panel covers one cycle of the pulsars.

(but a suprisingly large 25% of the mean pulsed light) is not in serious disagreement with the estimated upper limit of 2% of maximum intensity given by Miller and Wampler[4] on the basis of estimates from a TV picture taken through a strobing shutter with effective phase resolution of 20% of the pulsar period.

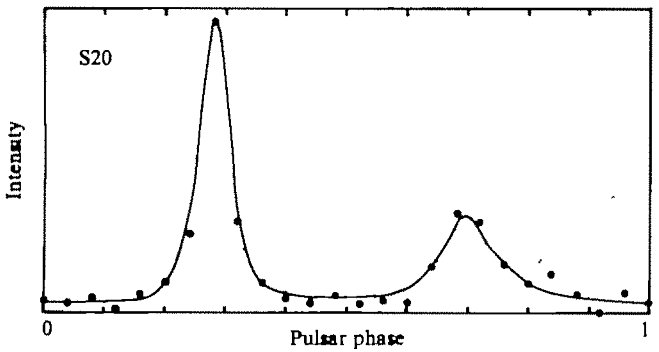

Fig. 3 Points are electronograph measurements of intensity of Crab pulsar summed in 25 equal sized phase bins: curve is high-time-resolution light-curve smoothed to 1.33 ms resolution and adjusted in amplitude, phase and base level to fit data. The minimum point of the curve (preceding the main pulse) is significantly above the zero level

The unpulsed background of the Crab pulsar which we observe with the IPCS is confirmed by an independent observation which was also independently reduced. In this observation (made on 7 November 1977) the photocathode of a McMullan electronographic camera[5] was masked to leave only a small area exposed in the focal plane of the RGO 0.9 m telescope (no filter, S20 photocathode). The picture area was stepped by deflection coils in synchronism with the pulsar period, to give 25 separate pictures, one of each phase bin. The response-time of the electronograph to a step of the deflection coils was very small compared with the 1.33 ms dwell-time for a picture. Using a PDS microdensitometer, each electronograph picture was scanned along the line joining the pulsar and its companion to the north-east, and the resulting profile across the pair of images was fitted with two one-dimensional point-spread functions, with similar form to the two-dimensional point-spread function used in the IPCS analysis. The ratio of the heights of the profiles is a measure of the intensity of the pulsar, because the electronograph produces an image whose density is linearly proportional to image intensity. We show the Crab pulsar light curve derived from an observation of duration 10 min in Fig. 3. The unpulsed background of the Crab pulsar detected with the unfiltered S20 electronograph is 3.7±0.8% of its peak intensity, in excellent agreement with the IPCS observations in U and B.

The ratio of steady/pulsed light for the Crab pulsar is similar in B, U (Table 1) and S20 wavebands. However, for the Vela pulsar the steady component may be weaker in the UV band than in the blue band. We used the χ^2-test to measure how similar the two light curves were (to within a scale factor). The probability of the value of χ^2 which measured the goodness of the match between the two observed curves was 4% ($\chi^2 = 14.9$, 7 d.f.). A better match between the U and B light-curves occurred when an extra steady intensity, equal to 0.26 of the mean U intensity, was added to the U light curve ($\chi^2_{\min} = 10.0$, probability 20%). Thus the steady light component of the Vela pulsar may be redder than the pulsed component.

For both pulsars the absolute magnitude of the steady, unpulsed component (Table 1) is too great to be attributed to thermal emission from the neutron star from which the pulsed radiation is beamed. The thermal radiation from a neutron star 9 km in radius was calculated[9] to have absolute magnitude $M_B = 19.4$ if the surface has a temperature $T = 2 \times 10^6$ K and would be $M_B \sim 25$ at $T = 10^4$ K.

There are several possible origins for the steady, unpulsed light component. (1) It may be pulsed light emitted from points distributed in space. Such light would reach the Earth with various arrival times and could contribute light at all phases. (2) A pseudo-steady component will also be seen if the pulses are so broad that they effectively fill the entire period. The high time resolution[3] light curve of the Vela pulsar, (Fig. 2*b*) hints at two weak pulses, similar to the two main pulses, but 180° offset in phase. The two main pulses may be produced by one pole of the rotating neutron star while the two weaker pulses are produced by the other pole. (3) The steady component may be thermal or other radiation from material near the pulsar (such as, a nebular wisp) that is reflecting or reprocessing energy in the pulses. Alternatively, if the beamed emission originates away from the neutron star, at the speed-of-light cylinder for example, the steady emission may be this radiation reflected from the surface of the neutron star.

The indication in Table 1 that the steady component of the Vela pulsar may be redder than the pulsed component, implies that reprocessing may be occurring, although it remains to be explained why almost as much light is received at Earth as a result of reprocessing as is received at Earth directly from the pulsar beam.

IUE observations of Large Magellanic Cloud members and detection of the 2,200 Å feature

THE dominant feature in the UV spectra of reddened stars in our Galaxy is the broad absorption feature of interstellar origin, centred near 2,200 Å and having a halfwidth of 350 Å (ref. 1). The wavelength position of this feature and the correlation of its strength with other interstellar extinction parameters, for example, the visual colour excess $E(B-V)$ are remarkably uniform throughout the Galaxy within 2 kpc from the Sun[2]. The 2,200 Å feature is attributed to small graphite spheres with radii between 100 and 200 Å (ref. 3), but a molecular origin cannot be ruled out[4]. It is, therefore, the most important feature to search for in the interstellar extinction laws of other galaxies. The Magellanic Clouds are the nearest extragalactic systems and the Large Magellanic Cloud (LMC), in particular the region near 30 Doradus, contains a significant amount of dust[5]. In the past few years considerable doubt has been expressed about the existence of the 2,200 Å feature in the LMC extinction law as derived from surface brightness measurements of the region around 30 Doradus[6], the results being rather inconclusive due to the difficulties arising from uncertainties in the luminosity function for the region concerned[7]. The interstellar extinction law can be reliably determined only from studies of the individual spectra of reddened and unreddened stars of similar spectral types. We present here the UV observations of a moderately reddened and a slightly reddened early type supergiant in the LMC obtained with the IUE. These observations answer the question of whether or not the agents responsible for the 2,200 Å feature are present in interstellar dust in the LMC.

The observations were obtained with the IUE at the low resolution mode ($\Delta\lambda \sim 6$ Å) over the entire wavelength range 3,200–1,150 Å. The spacecraft, its instrumentation, and the performance of the telescope, spectrograph and the SEC cameras are described elsewhere[8,9]. The reddened star is Sanduleak no. SK-69-108 (ref. 10). This star ($V = 12.10$, $B-V = 0.27$) is classified as B3I (ref. 11) and has a visual colour excess $E(B-V) \sim 0.45$. The comparison star, SK-67-108, is situated in a region free from nebulosity. It is classified as B0I (ref. 11) and its reddening, estimated to be $E(B-V) \sim 0.05$ arises mainly in our Galaxy.

Fig. 1 Observed flux distribution of SK-69-108 (*a*) and SK-67-108 (*b*) The points indicated by + signs are due to a fiducial mark.

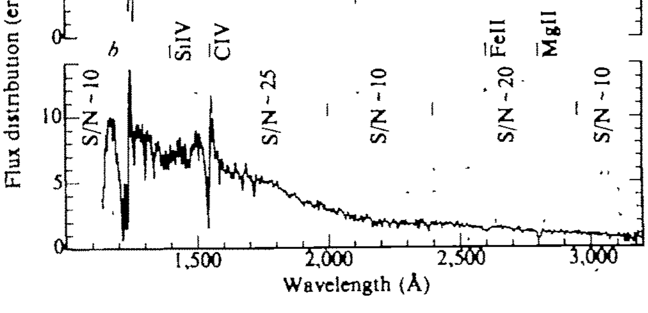

Table 1 Observations

Object	Species type	*U*	*B*	*V*	Image	Aperture	Exposure time (min)
SK-69-108	B3I	11.88	12.37	12.10	LWR1726 LWR1727 SWP1853	Large Large Large	45 90 80
SK-67-108	B0I	11.31	12 36	12.56	LWR1594 SWP1690	Small Small	20 20

LWR = long-wavelength redundant camera; SWP = short-wavelength prime camera.

The reddened star, SK-69-108, was observed with the large entrance slot (15×20 arc s), but the comparison star, SK-67-108 was observed with the small entrance slot (3×3 arc s). The photometric data, exposure times and image numbers are given in Table 1. The reduced spectra were provided by the IUE ESA observatory at Madrid, using the procedures described by Boggess *et al.*[9]. The wavelengths were checked using the positions of the major lines identified in the spectra. The raw image of each exposure was examined for saturated pixels, and only the unsaturated portions of the spectra were used. The net spectrum (observed minus smoothed background) was converted to absolute flux units using the preliminary system sensitivity functions provided by the Appleton laboratory.

Figure 1 shows the spectra of the reddened star SK-69-108 and the comparison star SK-67-108. The two peaks in excess of 20 units near 1,600 and 1,500 Å in the spectrum of SK-69-108 are due to charged particles incident on the camera; this is clear on the raw image. The mean signal-to-noise ratios computed from the counts recorded in the individual pixels of the raw image for different parts of the spectrum of each star are indicated in Fig. 1.

The C IV doublet at 1,550 Å in the spectrum of the unreddened star is very strong and shows a P-Cygni profile; on the other hand, the S IV doublet at 1,400 Å which, in early-type supergiants is usually as strong as C IV lines[12], is rather weak. Similarly, in the reddened star, the C IV doublet is considerably stronger than the S IV doublet. The most prominent line longwards of 2,500 Å is the Mg II doublet at 2,800 Å, and is present in both spectra. The line near 2,600 Å due to Fe II which appears clearly in the spectrum of the unreddened star is obscured in the spectrum of the reddened star by a fiducial mark on the raw image. Even at low resolution the spectra show a large number of lines; their identifications and spectroscopic comparisons with galactic standards will be presented elsewhere.

Table 2 Observed ($m_\lambda - m_{3100}$) colours

(Å)	SK-69-108	SK-67-108
1,300	0.604	−2 571
1,400	0.087	−2.440
1,500	−0.165	−2.381
1,600	−0 296	−2.389
1,700	−0.226	−2.126
1,800	−0.084	−2.000
1,900	0.301	−1.740
2,000	0.732	−1.523
2,100	1 079	−1.243
2,200	0 970	−1.037
2,300	0.726	−0.962
2,400	0.482	−0.934
2,500	0.308	−0.878
2,600	0.163	−0.704
2,700	0.009	−0.648
2,800	0.073	−0.412
2,900	−0.032	−0.368
3,000	−0.067	−0.249
3,100	0.000	0.000

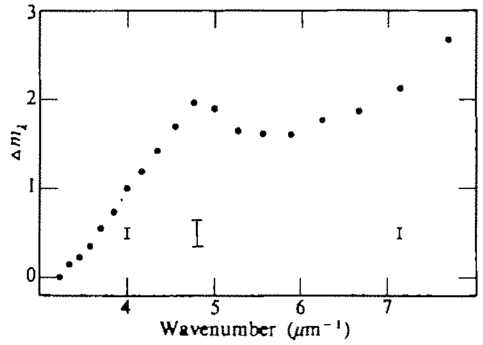

Fig. 2 The extinction law normalised to $\Delta m_\lambda = 0$ at $\lambda^{-1} = 3.23\ \mu\text{m}^{-1}$ and $\Delta m_\lambda = 1$ at $\lambda^{-1} = 4.0\ \mu\text{m}^{-1}$.

To improve the photometric accuracy, photometric bands ($\Delta\lambda = 100$ Å) have been constructed from 3,100 to 1,300 Å at intervals of 100 Å. The colours ($m_\lambda - m_{3100}$) for the reddened and comparison stars are given in Table 2: the errors of these colours range from 0.02 mag for the comparison star to 0.1 mag for the reddened star near 2,200 Å, where the fluxes are very low. The extinction curve Δm_λ against λ^{-1} (μm)$^{-1}$ normalised to $\Delta m_\lambda = 0$ at 3,100 Å and $\Delta m_\lambda = 1$ at 2,500 Å is shown in Fig. 2. These results are preliminary so no correction has been applied for the difference in the spectral types of the two stars.

The determination of the accurate shape of the UV extinction curve in the LMC and the comparison with the galactic extinction law require a larger sample of stars of accurately known spectral types. Although this is beyond the scope of the present work, the observations presented here establish the presence of the 2,200 Å feature in the UV extinction curve in the LMC. The feature which extends from 2,500 to 1,800 Å in the spectrum of SK-69-108 is similar to what is observed in our Galaxy.

The central source in the supernova remnant G127.1+0.5

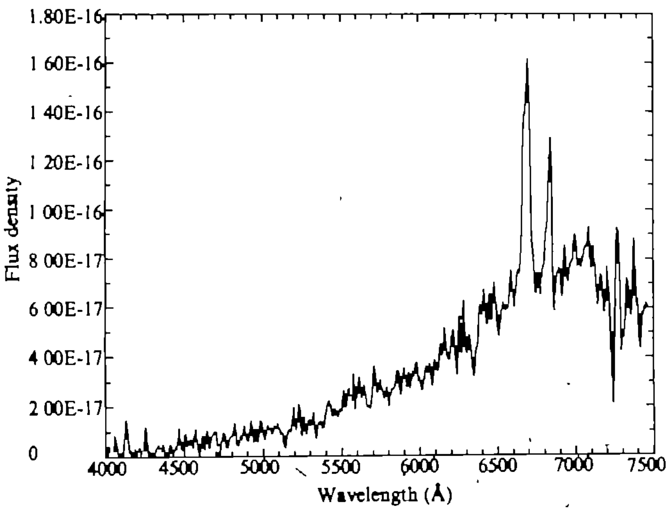
THE discovery[1] of a very small diameter radio source with a very flat spectrum at the centre of the galactic supernova remnant G127.1+0.5 has stimulated much interest[2–4]. Because the central source has unusual properties, and because the *a priori* probability of finding such an object at the very centre of a supernova remnant is exceedingly low, Caswell[1] suggested that the central radio source might be emanating from the collapsed stellar remnant of the supernova that produced the surrounding shell of radio emission. This intriguing idea was pursued by Salter, Pauls and Halsam[3] who showed that the extended supernova remnant is perfectly normal in shape and in radio spectrum, while the central source has a spectrum that is flat from 3 to 15 GHz at a flux density of 0.5 Jansky. A long-baseline interferometric measurement by Shaffer *et al.*[4] at 10.65 GHz showed that the angular size of the central source is about 0.0005 arc s. We now present evidence from direct optical observation suggesting that the link between the central source and the supernova remnant is purely circumstantial.

Caswell suggested, based on positional coincidence to 0.5 arc s, that a red object of about 19 mag was identical with the source of radio emission. Inspection of the Palomar Sky Survey shows that the object is diffuse on the red plate, and invisible on the blue plate. The entire region near G127.1+0.5 shows signs of heavy obscuration.

We have made spectrophotometric measurements of the red diffuse object with the image dissector scanner at the 4-m Mayall telescope of Kitt Peak National Observatory. Our observations were obtained on 28–29 August 1978, a night of excellent seeing and transparency. On the slit-viewing television, the object was clearly nonstellar. We integrated for 4,500 s and obtained simultaneous object and sky spectra through two apertures of diameter 3.2 arc s separated by 52 arc s. The net spectrum due to the object covered the wavelength interval 4,000–7,500 Å with a resolution of about 20 Å. Figure 1 shows the distribution of flux density f_λ in erg cm^{-2} s^{-1} Å^{-1} obtained by comparing the counts observed on G127.1+0.5 with those obtained on standard stars of known flux distribution.

As Fig. 1 shows, the spectrum of the object consists of a very red continuum with two broad emission blends. The two blends are at wavelengths of 6,691 Å and 6,841 Å, and have integrated fluxes in the ratio 2.3:1. We identify the stronger, broader feature at 6,691 Å with the familiar blend of [N II] 6,548.1 Å, Hα 6,562.8 Å, and [N II] 6,583.6 Å. The feature observed at 6,841 Å, we identify with the [S II] doublet 6,717.0, 6,731 Å, and we propose that the object is a galaxy.

Fig. 1 Flux density F_λ (erg cm^{-2} s^{-1} Å^{-1}) plotted against wavelength for the diffuse red object at the centre of the supernova remnant G127.1+0.5 ($\alpha = 01$ h 25 min 08.3 s, $\delta = +62° 50' 59''$ (1950)). The two broad emission features at 6,691 Å and at 6,841 Å are identified with [N II]+Hα and with [S II] at a redshift of 5,375±200 km s^{-1}.



Although the individual lines are not resolved by our instrument, we can make a reasonable estimate for the relative line strengths within the blends by using the spectrophotometry of typical radio galaxies compiled by Costero and Osterbrock[5]. Based on their work, we expect that [N II] 6,584 Å will have about the same strength as Hα, and that [N II] 6,548 Å has one-third that strength. We expect that the [S II] 6,717 Å line will have the same strength as the 6,731 Å line. On that basis we compute effective wavelengths for the blends that yield a redshift $cz = 5{,}375 \pm 200$ km s^{-1}. We note that the observed ratio of [N II]+Hα to [S II] is about the same in this object as in the radio galaxies studied by Costero and Osterbrock.

If the object is at a distance of ~100 Mpc, (for $H_0 = 55$ km s^{-1} Mpc^{-1}) then it has an absolute magnitude M_v of about $-16 - A_v$. We can estimate the absorption A_v by noting that the continuum fluxes at 7,000 Å and 5,800 Å are in the ratio 2.7:1. Absolute spectrophotometry by Oke and Sandage[6] indicates that the intrinsic ratio is about 1:1. If we attribute the reddening to dust that follows the Whitford relation[7,8] the required extinction at the visible is $A_v = 5$ mag. Then the absolute magnitude of the object is near $M_v = -21$, the absolute magnitude of a luminous galaxy. The presence of large extinction is corroborated by the low galactic latitude of the source ($b = +0.5°$), the appearance of the region on the Palomar Sky Survey, the absence of the object from the blue plate, and the absence of short wavelength emission lines, such as [O III] 5,007 Å, that are prominent in radio galaxies.

At a distance of 100 Mpc, the radio power of the galaxy integrated to 15 GHz is about 8×10^{40} erg s^{-1}, coming from a region of diameter 0.2 pc. For comparison, the compact source in M 87 has a diameter of 0.04 pc, and about $\frac{1}{4}$ the emitted energy per unit frequency at 15 GHz (ref. 9).

We believe that a completely consistent picture of the central source in G127.1+0.5 is that it is a luminous galaxy at a distance of ~100 Mpc that contains a compact and energetic radio source. Although the circumstantial evidence linking the central source to the supernova remnant is intriguing, we believe that the positional coincidence is mere chance.

Because G127.1+0.5 was the most compelling case for a compact radio source associated with a supernova remnant, the demonstration that this object is a chance event makes it seem likely that other suggested radio objects near supernova remnants may well be just the superposition of background sources on galactic remnants.

Kitt Peak National Observatory is operated by Aura, Inc., under NSF contract. R.P.K. was supported by NSF grant AST 77-17600.

Magnetic field in the primitive solar nebula

METEORITES which fall to Earth's surface generally carry permanent magnetisation which probably was acquired early in their history[1]. In particular, carbonaceous chondrites, which are generally assumed to be virtually unaltered relicts from the earliest Solar System processes of condensation and accretion[2], have apparently been magnetised in magnetic fields with intensities in the range 0.1–10 G (refs 1, 3, 4). The origin of the magnetising field has remained obscure; explanations proposed to account for the field, include a strong central solar field in the early Sun, an intense solar wind magnetic field, magnetic fields generated in large parent objects—ancestral to the meteorites—and the interstellar magnetic field transiently compressed during the Solar System's formation. So far as we know, none of these mechanisms has been shown quantitatively capable of accounting for measured meteoritic remanence[5]. We suggest here that the magnetic field recorded in the remanence of carbonaceous chondrites may have been produced by a self-excited hydromagnetic dynamo in the gaseous preplanetary nebula from which the Solar System is thought to have formed.

The Solar System is generally thought to have formed from the collapse of gaseous interstellar matter which, because of the system's angular momentum, settled into a disk shaped nebula. Several models to describe the evolution of such a nebula have been computed[6–10]. While these models are not unique, they do give some indication of the processes and conditions involved in the early evolution of the Solar System. For specificity, we will use the models recently computed by Cameron[10], which consist of turbulent and differentially rotating, gaseous disks having characteristic radial scales of several astronomical units and characteristics half thicknesses of a few times 10^{12} cm. In the models the gas density characterising the region at several astronomical units from the centre is $\sim 3\times10^{-10}$ g cm^{-3} and the characteristic turbulent fluid velocity is $\sim 4\times10^{4}$ cm s^{-1}.

Turbulent motions in such a differentially rotating gas nebula can generate a large-scale magnetic field through hydromagnetic dynamo action if the electrical conductivity of the gas is sufficiently high. At the low temperatures and high gas densities typical of a preplanetary nebula, the electron density in thermodynamic equilibrium is too low to support hydromagnetic processes. These processes then require nonequilibrium effects to raise the electron density and electrical conductivity. The recent discovery by Lee *et al.*[11] of anomalously large concentrations of ^{26}Mg in some meteorite samples suggests that the short-lived radioactive isotope ^{26}Al may have been present in abundant quantities in the nebular material—the ^{26}Al produced in a nearby supernova thought to have precipitated the Solar System's formation. Cameron and Truran[12] have estimated that ~2% of the Solar System's heavy elements may have been inserted into the nebula by such an event. Ionising radiation from the decay of short-lived isotopes drives up the electrical conductivity of the nebular gas. In conditions which characterise nebular models the conductivity may be so large that the magnetic Reynolds number exceeds unity, thus coupling the behaviour of magnetic fields to the fluid motion.

In a turbulent, differentially rotating gas the efficacy of the fluid motions for generating a magnetic field can be expressed through a dimensionless dynamo number[13,14]

$$N = \gamma\Gamma\delta^3/\eta^2 \qquad (1)$$

where γ measures the shear produced by differential rotation, Γ measures the helicity of the turbulent convection, δ is the physical scale of the magnetic field, and η is the magnetic diffusivity ($\eta = c^2/4\pi\sigma$; c is the speed of light and σ is the electrical conductivity).

Parker has investigated the regenerative modes of a hydromagnetic dynamo operating in a differentially rotating turbulent disk of gas[16] and has found that magnetic fields are produced when $N \gtrsim 6$. It will be shown elsewhere[5] that this condition is satisfied in the model nebula when $\sigma \gtrsim 400$ s^{-1}. Consolmagno and Jokipii[15] suggest that ionisation produced by the decay of ^{26}Al can produce an electrical conductivity of the order of 10^3 s^{-1} in the nebula, thus satisfying the condition for magnetic field generation.

The maximum field intensity that might be realised by the dynamo production process can be estimated. We will consider two dynamical mechanisms that limit the strength of the field. First, because the Coriolis force provides the ordering influence that produces efficient magnetic field generation in the dynamo process, an estimate of the maximum realisable field intensity can be obtained by setting the Coriolis force equal to the Lorentz force produced by the magnetic stress[14]. Thus, in order of magnitude

$$\rho V\Omega \sim \langle B^2\rangle/4\pi\delta \qquad (2)$$

Taking, in equation (2), the density $\rho \simeq 3\times10^{-10}$ g cm^{-3}, the characteristic turbulent velocity $V \simeq 4\times10^{4}$ cm s^{-1}, $\delta \simeq 5\times10^{12}$ cm, the disk scale height, and Ω the Keplerian angular velocity at several astronomical units from the Sun, we find for the characteristic saturation field intensity

$$\langle B^2\rangle^{1/2} \sim 5 \text{ G} \qquad (3)$$

This is the same order of magnitude as the magnetic field which would be necessary to account for meteorite magnetic remanence.

Another mechanism which limits the field strength is ambipolar diffusion, through which the ionised gas and magnetic field slips past the neutral material[17]. Using the results of Consolmagno and Jokipii[15] and equating the ambipolar diffusion time to the turnover time of the turbulent fluid motions one finds that ambipolar diffusion limits the further growth of the magnetic field when the field intensity rises to the order of 1 G.

The values derived here are to a large extent model-dependent and will evolve along with our ideas about the characteristics of a preplanetary nebula. However, these crude and preliminary calculations, taken with the measured remanence of primitive meteorites, suggest that a large-scale magnetic field was generated by gas motions in the preplanetary solar nebula. The intensity of this field may have been as high as 1–10 G.

Such an intense field could have had important dynamical influences on the evolution of the gaseous nebula. It is easy to see that the timescale for redistribution of angular momentum (and thus mass) driven by the magnetic stress, arising from field intensities in the range 1–10 G, is in the range 10^2–10^4 yr. This is the same range estimated for the evolutionary time scale of the primitive solar nebula[10].

I thank J. R. Jokipii for discussions. This research was supported in part by NASA.

The solar wind influences plasmasphere electron content

MAGNETOSPHERIC plasma convection has been reviewed in detail by Axford[1]. A viscous-like interaction between plasma and magnetic field and magnetic-field-line merging have been suggested as mechanisms producing magnetospheric convection. In either model, convection is sustained by a dawn–dusk electric field (E_{conv}) which has been shown[2–4] to depend on solar-wind speed V_{sw}. Vasyliunas[2] suggested a linear dependence, but Mendillo and Papagiannis[3] estimated that the convection electric field varies nearly quadratically with solar wind speed—this conclusion was supported by Kivelson[4]. The convection field E_{conv} and hence solar wind speed have important roles in determining the location of plasmaspause[5,6]. Model calculations assuming enhancement of the solar wind showed the plasmapause everywhere to be located at smaller L coordinates[7] (L is the McIlwain[8] magnetic shell number). The location of the duskside bulge of the plasmapause has been shown to be inversely related to the solar wind speed[3]. The total plasmasphere electron content (N_P) is supposed to increase with increase in L, the rate of increase being dependent on the density distribution assumed and the L values under consideration[9]. Thus one expects an increase in N_P to be associated with a decrease in V_{sw} and vice versa. In this letter we give an experimental verification of this for two magnetic storms associated with large changes in V_{sw}, and for which N_P and V_{sw} data are available. The results will prove useful in interpreting the disturbed time behaviour of N_P.

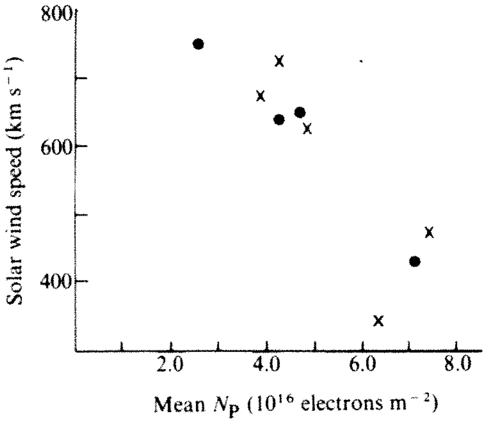

Fig. 1 Solar wind speed plotted against daily mean N_P for the two storms (see Table 1). ●, Storm of 1-5 Nov. 1975; ×, storm of 28 Nov.-2 Dec. 1975.

Electron content measurements were made between October 1975 and July 1976 at Ootacamund (11.4° N, 76.6° E, mag dip 6°) by Faraday rotation and the group delay techniques using radio beacon signals from the geostationary satellite ATS-6 at 35° E. The difference in electron contents measured by these techniques gives the electron content of the plasmasphere[10]. The details of the techniques and the accuracies involved are discussed by Davies *et al.*[11,12]. The daily mean N_P values for the pre-storm and during-storm days are compared with the corresponding solar wind speeds in Table 1. For the first storm the pre-storm solar wind data are not available for the first day. Solar wind speeds are plotted against mean N_P for the corresponding days in Fig. 1. All three pre-storm days have large mean N_P values but low solar wind speeds (~400 km s^{-1}) whereas the during-storm solar wind speeds were greater by a factor of 1.5 with mean N_P correspondingly decreased. This is the first experimental evidence from an equatorial station confirming an inverse relationship between plasmasphere electron content N_P and solar wind speed V_{sw}. The correlation coefficient between N_P and the V_{sw} is -0.92 ± 0.05. A linear relationship between N_P and V_{sw} is obtained by the least square method and is given by $N_P = 12.5(1 - V_{sw}/1000)$ where V_{sw} is the solar wind speed in km s^{-1} ($V_{sw} \leq 750$).

Table 1 Comparison of pre-storm and during-storm plasmasphere electron content and solar wind speed

Storms	MPO	Maximum D_{ST} (γ)	Days	V_{sw} (km s^{-1})	Daily mean $N_P \times 10^{16}$ electrons m^{-2}
1-5 Nov. 1975	2 Nov. 1100 UT	−76	1* Nov.	—	4.5
			2*	430	7.0
			3	650	4.6
			4	750	2.5
			5	640	4.2
28 Nov.– 2 Dec. 1975	29 Nov. 0700 UT	−53	28* Nov.	350	6.7
			29*	475	7.3
			30	625	4.7
			1 Dec.	675	3.8
			2	725	4.2

MPO is the main phase onset; D_{st} is the ring current intensity index.
* Pre-storm days.

Storm-time behaviour of N_P has been discussed by various workers[13–15]. Consideration of solar wind speeds is important in interpreting the observed results and a detailed study of storm-time behaviour of N_P at Ootacamund is underway.

The experiment at Ootacamund was a joint undertaking of Physical Research Laboratory, Ahmedabad, India and NOAA, Boulder, Colorado. We thank Professors K. Davies and G. Swarup for collaboration and facilities respectively and Miss Chhaya R. Shah for computational help. The research at PRL is supported by the Department of space, Government of India.

A new amorphous silicon-based alloy for electronic applications

THERE is a need for alternative energy sources. Photovoltaics are an attractive possibility, but their application has been limited by economic considerations in single-crystal materials, and for physical reasons such as grain boundaries in polycrystalline materials. Amorphous semiconductors are especially attractive in this regard because they are basically much less expensive than their crystalline counterparts and because they possess a direct band gap with a high value for the optical absorption coefficient. We report here the development of a new

0028–0836/78/0276—0482$01.00

Table 1 Comparison of the new alloy with the best silicone–hydrogen alloy fabricated

Type of amorphous alloy	Si–F–H	Si–H	Comments
Optical band gap E_0	1.65 eV	1.55 eV (refs. 11, 12)	Measured using photoconductive data
Minimum density of localised states $N(E)$	10^{16} cm^{-3} eV^{-1}	10^{17} cm^{-3} eV^{-1}	As measured by the field-effect experiments. The analysis[1] neglects surface states and hence these numbers represent an upper limit to $N(E)$
Intrinsic behaviour	ΔE(~0.8 eV) and σ_{RT} (10^{-10}–10^{-8}(Ωcm)$^{-1}$) are weakly dependent on deposition temperature between 400 and 700 K	ΔE(0.8–0.5 eV) and σ_{RT}(10^{-11}–10^{-7}(Ωcm)$^{-1}$) are strongly dependent on deposition temperature between 350 and 600 K (ref. 13)	σ_{RT} and ΔE refer to the room temperature conductivity and conductivity activation energy
Doping efficiency	Values of $\sigma_{RT} \sim 5$(Ωcm)$^{-1}$ and $\Delta E' \sim 0.05$ eV attained using very small concentrations of PH_3 (500 v.p.p.m.) and AsH_3 (50 v.p.p.m.)	Values of $\sigma_{RT} \sim 10^{-2}$ (Ωcm)$^{-1}$ and $\Delta E \sim 0.20$ eV attained using 4×10^3 v.p.p.m. PH_3 in SiH_4	$\Delta E'$ refers to an estimate of the activation energy at room temperature by drawing a tangent to the σ–T curve
Mode of deposition	Radio frequency glow discharge in SiF_4/H_2	Radio frequency glow discharge in SiH_4 gas	
Photostructural changes	Absent	Major[6]	
Photoconductivity σ_L	(1–3)10^{-4}(Ωcm)$^{-1}$	(1–3)10^{-4}(Ω cm)$^{-1}$ (ref. 14)	Measured under AM − 1 incident radiation of power 90 mW cm^{-2}
Infrared peaks			Thick deposits (~5 μm) made on crystalline Si substrates
2,100 cm^{-1}	Very small	Present	Usually atributed to SiH_2 (ref. 15)
2,000 cm^{-1}	Absent	Present	Usually attributed to Si–H stretch[15]
1,000 cm^{-1}	Present	Present	Usually attributed to Si–O stretch[15]
900 cm^{-1}	Absent	Present	Usually attributed to H–Si–H scissors[15]
830 cm^{-1}	Present	Absent	Attributed to Si–F stretch[11]
640 cm^{-1}	Present	Present	Attributed to Si–H wag[15]
Hydrogen content	~0.5%	>5%	Estimated from the integrated absorption coefficient by using infrared techniques[16]
Fluorine content	~2 to 6% dependent on ratio of SiF_4/H_2	None	Estimated from ESCA measurements

alloy that eliminates the physical problems associated with the silicon–hydrogen alloys.

Amorphous semiconductors ordinarily have a large density of localised states which act as traps which lead to low values for the drift mobility and the recombination time of free carriers. For example, elemental amorphous silicon is of little technological importance because it contains a density of localised states in excess of 10^{20} cm^{-3} eV^{-1}. Madan *et al.*[1,2] reported that amorphous-silicon films decomposed from silane gas by an r.f. glow discharge and deposited on a heated substrate have a much reduced density of states at the Fermi level, of the order of 10^{17} cm^{-3} eV^{-1}. This material has subsequently been shown to be an amorphous silicon–hydrogen alloy[3]. In addition, Spear and Le Comber[4] showed that this alloy could be doped with phosphorous and boron; Carlson and Wronski[5] further demonstrated that it had a sufficiently high carrier lifetime to yield solar cells of up to 5.5% efficiency. Nevertheless, the still relatively high density of localised states throughout the gap leads to inefficient doping and limits the carrier lifetime. In addition, undesirable photostructural changes have been observed[6] and the material effuses hydrogen above 450 °C (ref. 3). Despite many efforts, there has been no success in overcoming these basic problems.

The new alloy has silicon and fluorine as its main structural components. This alloy is multi-elemental and includes hydrogen, and can also include other elements such as oxygen without deleterious effects. The steric chemical and electrical properties associated with our new alloys will be described elsewhere[7,8]. Table 1, which condenses data taken from more than 600 sample depositions, compares our Si–F–H alloy (fabricated from the gas ratio of $SiF_4/H_2 = 10/1$) with the best Si–H alloy.

Table 1 shows that our material is in almost all properties, except for photoconductivity, distinctly different from the best Si–H alloy which makes it attractive for electronic device applications. Of special interest is the fact that the intrinsic properties of our material are only weakly dependent on the substrate temperature, much like multi-component chalcogenide glasses, and in sharp distinction from the strong dependence observed in silane-decomposed films.

With regard to the infrared spectrum, it is important that the peak at 2,000 cm^{-1} corresponding to the silicon–hydrogen stretch does not appear in our films. The peak at 2,100 cm^{-1} is ordinarily assigned to the SiH_2 group which has a wag at 640 cm^{-1} and a H–Si–H scissors mode at 900 cm^{-1}. The scissors mode is also absent in our film. Hydrogen through its various bonding configurations with other elements can be responsible for localised states in the gap[9,10]. A full interpretation of this point and the above data will be given elsewhere[11].

The new alloy reported here is superior to silane-based films for electronic applications. In particular, there is a much lower density of states at the Fermi level. This leads to much larger doping efficiencies. In fact, effective n-type doping has been achieved with only 50 v.p.p.m. AsH_3 in the premix. Furthermore, no photostructural effects have been observed. Because of its highly desirable characteristics, this material seems to have a potential for general semiconducting applications as well as for photovoltaics.

We thank David Adler, Melvin Shaw, Hellmut Fritzsche, Richard Flasck and Morrel Cohen for valuable discussions, and also Edward Benn, Larry Christian, and Thomas Anderson for technical assistance.

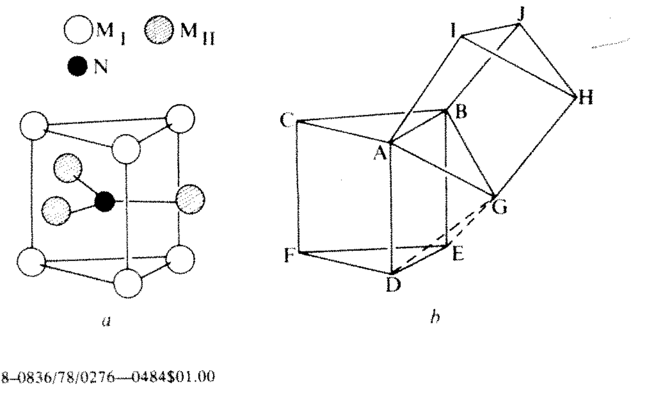
A new structural model for transition metal–metalloid glasses

CONCEPTUAL notions of the structure of metallic alloy glasses have generally developed from purely geometrical sphere-packing models proposed for liquid[1] and glassy[2,3] monoatomic metals. The assumption on which these models are based is that the glass consists of a random arrangement of spherical atoms of each element—the so-called dense-random-packed (DRP) model. Glassy 'metallic' alloys of two or more chemically dissimilar elements can also be represented in this way, local atomic arrangements arising by chance, constrained only by geometrical factors such as the ratios of atomic radii. Construction of the model described here is based on an alternative principle commonly observed in amorphous solids of other types, namely that local structure is well-defined and almost always identical to that found in crystalline forms of the material. The properties of such a 'stereochemically designed' model have been computed and are found to be in reasonable agreement with high resolution neutron scattering data for glassy palladium–silicon alloys.

Metallic alloy glasses can be subdivided into two broad categories: alloys of two or more metallic elements (metal–metal glasses) and those systems in which a non-metallic or semimetallic (metalloid) element is essential for glass formation. Within the latter category, the binary and ternary alloys of the transition metals, particularly Fe, Co, Ni, Pd and the non-metallic elements B, C, P and Si comprise the most important series, commercially and scientifically. Dense-random-packed structures for these glasses allow the non-metallic atom to occupy polyhedral cavities of several different types, only one of which resembles the local coordination observed in the crystalline state. Structures represented by this model are essentially different from those of most other types of glass: in oxides and chalcogenides, amorphous elemental and compound semiconductors, organic 'molecular' and polymeric glasses, the nearest-neighbour coordination and local symmetry, at least, are well defined. It is clearly incorrect, for example, to represent a glassy silicate as anything other than a non-periodic arrangement of relatively undistorted SiO$_4$ tetrahedra[4,5], the latter being, of course, the local structural units on which nearly all simple silicate lattices are based.

Fig. 1 *a*, Regular trigonal prismatic coordination; and *b*, edge-sharing of polyhedra observed in the Fe$_3$C, cementite structure. Note that the M$_\mathrm{I}$ atom G for the upper prism occupies an M$_\mathrm{II}$ site in relation to the lower.



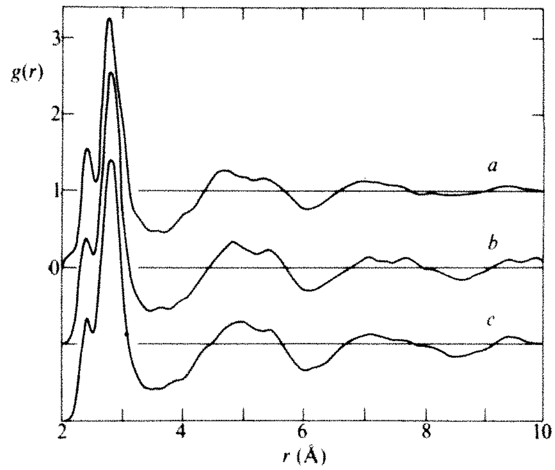


Fig. 2 Pair correlation function $\rho(r)/\rho_0$ for glassy Pd$_4$Si, where $\rho(r)$ is the atomic density and ρ_0 the average density. *a*, Experimental data derived from neutron scattering measurements[12] with $Q_{\max} = 25$ Å^{-1} ($Q = 4\pi \sin\theta/\lambda$). Curves *b* and *c* refer to spherical cores of the model of radius 8.6 and 10 Å respectively. The latter cluster is not fully dense but nonetheless gives a better representation of $g(r)$ beyond ~5 Å where the effects of finite model size become important. Computed curves have been convoluted with gaussian broadening functions to simulate the effects of thermal vibration and transformation of experimental scattering data over a limited range of Q. Values were chosen to reproduce the breadth of each component of the split first peak at 2.4–2.9 Å (half widths are 0.094 Å for Si-Pd and Si-Si, and 0.14 Å for Pd–Pd correlations).

Local structure in the borides, carbides, phosphides and silicides of most of the transition metals which form glasses on quenching from the melt is also well defined in the crystalline state[6]. The coordination polyhedron of the non-metallic element, N, consists of a subshell of six metal atoms, M$_\mathrm{I}$, forming a somewhat distorted trigonal prism with three further M$_\mathrm{II}$ atoms capping the square faces at somewhat larger and even more variable M–N distances (Fig. 1*a*). Do the glassy forms of these materials therefore also consist of non-periodic arrangements of such units? Are glasses, formed from palladium and silicon or iron and boron, random amorphous alloys of the two pairs of elements, or glassy silicides and borides with well defined local symmetry similar to that found in the crystalline forms?

The influence of localised, possibly directional chemical bonding, the formation of relatively large groups of atoms with low symmetry, are relevant factors—if only in a qualitative sense—to theories of glass formation and stability. Arrangements of spherical atoms into a periodic array involves relatively simple processes, whereas ordered packing of large assymetric 'molecular' fragments requires a series of correlated motions. Glass formation is therefore more likely in the latter case, as has been noted elsewhere[7]. Alternative theories stress the stability gained when atoms of one element fit within cavities formed by random packing of the other[8] or collective properties of the valence electrons—specifically, the reciprocal space relationship between the Fermi momentum and the first peak of the structure factor[9]. In neither of the latter treatments is bonding considered explicitly. The importance of each of these three factors in particular alloy systems is a source of controversy[10].

This paper describes properties of an atomic model for metal–metalloid glasses in which trigonal prismatic NM$_6$ units are connected in an essentially random manner, with an edge-sharing arrangement (Fig. 1*b*) observed in many of the crystalline forms of these materials, notably the Fe$_3$C cementite structure. A physical model, built from 3-cm polystyrene spheres, was used to guide a computer program which generated the atomic coordinates of a cluster with a radius of about 12 Å containing 434 M and 108 N atoms. Atomic coordinates are unrealistic at this stage for two reasons. First, regular, undistorted trigonal prisms were used to simplify the construction algorithm; however, N atoms are generally too large to fit within

0028–0836/78/0276—0484$01.00

a regular trigonal prism which must therefore distort. Second, the physical model allows no positional adjustment once units are fixed in place and it is impossible therefore to build a model which does not contain relatively large voids on the one hand and 'compressed' atoms on the other, although excessive overlap of atoms can be avoided in both the hand-built and computer-generated models. Coordinates were refined by moving atoms sequentially to minimise the energy calculated using a Lennard–Jones pair potential

$$V_i = 4\varepsilon_{ij}\sum_j (R_{ij}^{12} - R_{ij}^{6})$$

Here, V_i is the energy of atom i, $R_{ij} = 2^{-1/6}\,R_{ij}^0/r_{ij}$, where r_{ij} is the actual distance between the atoms i and j and R_{ij}^0 the eqilibrium distance. The quantities ε_{ij} are approximately proportional to weighted sums of the cohesive energies of each element and have been obtained from the tabulation of Gschneider[11]. In the summation, j includes all nearest-neighbour atoms: for M–M pairs, atoms within a sphere of radius 3.2 R_M^0 centred on the origin atom are included where R_M^0 is the radius of the metal atom. Atoms are free to move in and out of this sphere as energy minimisation proceeds. For N–M pairs, however, trigonal prismatic local coordination is emphasised by attempting to keep the local environment of the N atoms invariant, the program attempts to retain the original six nearest-neighbour M neighbours of each N atom throughout the calculation. Moreover, the average bond length is set to the N–M_I distance found in crystals. Further M_{II} metal neighbours lying with 2.4 R_M^0 are included in the summation: these atoms are unconstrained and a larger equilibrium N–M_{II} distance is assumed.

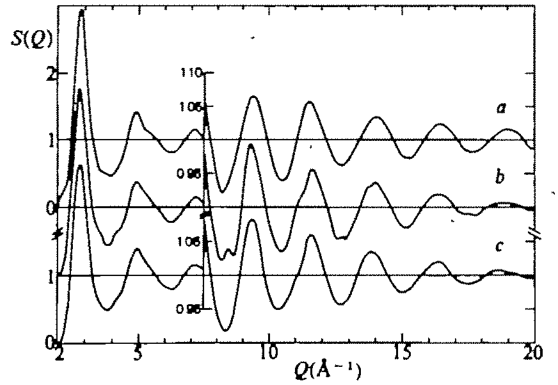

Fig. 3 Neutron structure factors $S(Q)$ for a–Pd_4Si: labelling as for Fig. 2. The computed curves were obtained by a sine transform of real-space data (over the range 0–15 Å) modified by a weighting function sin $(\pi r/12)/(\pi r/12)$ introduced to suppress errors in the radial distribution function beyond about 8 Å.

Figure 2 shows the pair correlation function $g(r) = \rho(r)/\rho_0$ computed for glassy Pd_4Si, compared with experimental data derived from neutron scattering measurements[9]. Here, $\rho(r)$ is the atomic radial density function and ρ_0 the average atomic density. The function $g(r)$ has been calculated for spherical cores of radius 8.6 and 10 Å. As the model is small, the average density is a function of the cluster radius—a core of radius 8.6 Å is almost fully dense whereas at 10 Å, parts of the spherical core lie beyond the edge of the model. The average density, 10.4 ± 0.2 g cm^{-3} is in good agreement with experimental values for a-Pd_4Si of 10.25 (ref. 3) and 10.5 g cm^{-3} (Suzuki, personal communication). The neutron scattering factor, $S(Q) = 1 + 1/Q \int_0^\infty 4\pi r(\rho(r) - \rho_0)\sin Qr\,dr$ is shown in Fig. 3.

Although there are some discrepancies between computed and experimental $g(r)$ values—notably the height of the first (Si–Pd) peak at 2.4 Å and the position of the first component of the second split peak at 4.8 Å, overall agreement is reasonable. Agreement between experimental and computed neutron scattering data, Fig. 3, is excellent, the somewhat more rapid decay of oscillations in $S(Q)$ for the model beyond about 17 Å^{-1} indicating greater order in the real glass.

This work cannot conclusively resolve the issue of defined (chemical) compared with random (geometrical) local structure, scattering data are almost certainly insufficiently sensitive to discriminate between the two models. However, the defined local coordination model apparently gives a good representation of transition metal–metalloid glasses, especially those which have been quenched relatively slowly or have been subsequently annealed and thus approximate to the minimum free energy amorphous state–an 'idealised' glassy state–the vitreous equivalent of the perfect single crystal. In this context it is interesting that atomic coordinates can be generated for a model in which the local coordination around silicon atoms is less well defined (by removing the distinction between N–M_I and N–M_{II} distances mentioned above). Changes in $S(Q)$ thus introduced give a good representation of experimental changes in X-ray scattering observed when metallic glasses are annealed at temperatures below their glass transition or crystallisation temperatures[13,14], the more ordered model corresponding most closely to an annealed glass.

This work has been carried out during the tenure of an SRC Senior Fellowship. I thank the SRC and Pilkington Brothers Ltd for their support.

Transient effects in laboratory measurements of compressional wave velocity and electrical conductivity

LEE *et al.*[1] demonstrated the effect of temperature on the electrical conductivity of high grade saturated metamorphic rocks, when held at constant effective pressures. Apart from initially showing an increase in conductivity with temperature, it was demonstrated that conductivity at higher temperatures was time dependent. When a sample was held at a constant temperature (~250 °C) the conductivity decreased exponentially with time, so that after ~10 h, there was little further change observed. As the temperature was lowered the conductivity decreased from this steady state value, and with further thermal recycling the conductivity was recycled along a path

0028–0836/78/0276—0485$01.00

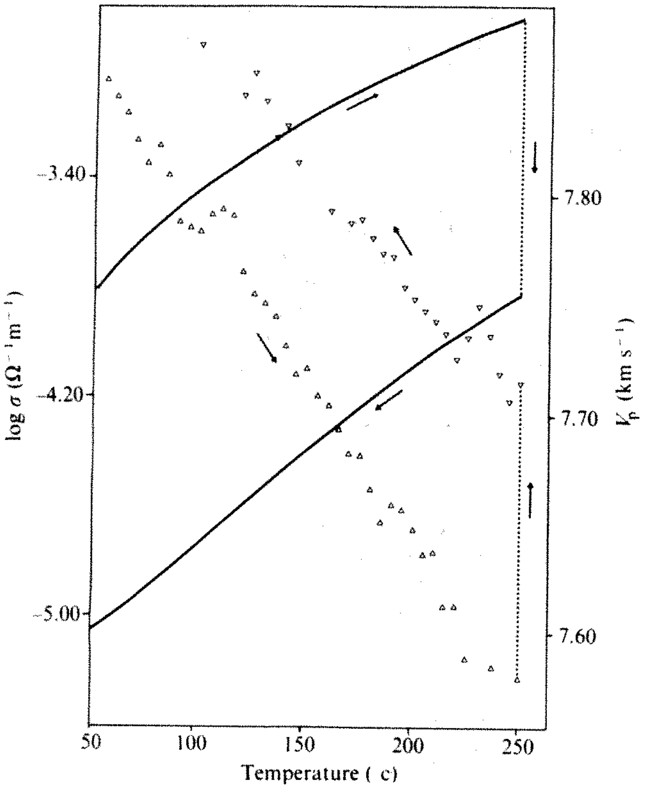

Fig. 1 Electrical conductivity and compressional wave velocities for a saturated (0.5 M NaCl) sample of ultramafic rock as a function of temperature. The electrical conductivity is described by the solid line and compressional velocity by triangles, inverted for decreasing temperature. The transient effect at elevated temperatures is signified by dotted lines. Confining pressure, 0.35 GPa; pore pressure, 0.10 GPa.

uite different from that taken with the initial temperature icrease. The results implied that due regard should be paid to iis transient effect when making laboratory electrical ieasurements on rock samples in simulated upper crustal onditions. Time-dependent effects at elevated temperatures ave also been observed in laboratory measurements of ompressional wave velocities[2,3]. Spencer and Nur[2] in their udy of the Westerly Granite showed that thermal recycling at evated pressures tended to produce an irreversible increase in ompressional velocities. Further investigation demonstrated a ystematic time-dependent increase of velocity while the sample was held at a fixed elevated temperature (495 °C). We report here the direct comparison of these transient variations of electrical conductivity and compressional velocity. In our experiments we have measured these parameters simultaneously on the same sample to ensure that any variables such as pore pressure, confining pressure and temperature are identical. Any comparison of separate measurements of conductivity and velocity on the same sample in different experiments is unsatisfactory due to the irreversible nature of the process being studied. Even if two samples from the same rock are used there may be significant differences in cracks and mineralogy, which would give erroneous results.

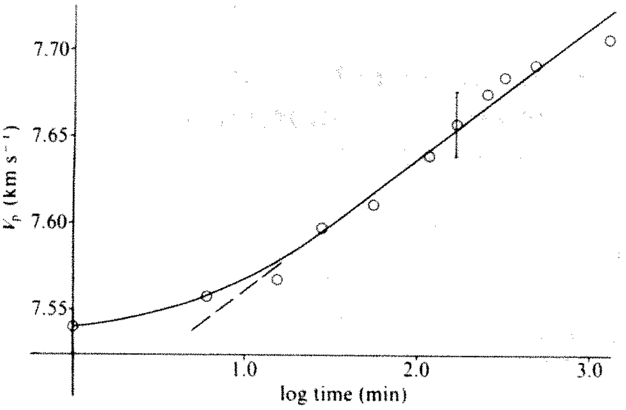

Fig. 2 Compressional velocity as a function of log time for a saturated (0.5 M. NaCl) sample of ultramafic rock while held at 250 °C. Confining pressure, 0.35 GPa; pore pressure, 0.10 GPa.

The apparatus we used is similar to that of Lee *et al*[1], except for the introduction of lithium niobate transducers within the metal electrodes. A pulse transmission method was used[2], with a 60 V (0.5 mHz) square wave applied to the input transducer and the resultant output signal (received by the output transducer) displayed on a dual-beam oscilloscope. The transit time through the sample was measured by a Hewlett-Packard timer counter triggered by the input pulse and terminated by a marker pulse, visually aligned with the first arrival of the output signal. This method introduced an error of ~0.5% between different measurements and an absolute error of ~3% in velocity readings.

A wide range of rocks including granite, quartzite, gneiss, schist, gabbro and basalt have been studied at elevated pressures and temperatures (confining pressure 0.35 GPa; pore pressure 0.1 GPa; temperature up to 250 °C). All have shown the transient decrease in conductivity described by Lee *et al.*[1], and with this a corresponding velocity increase.

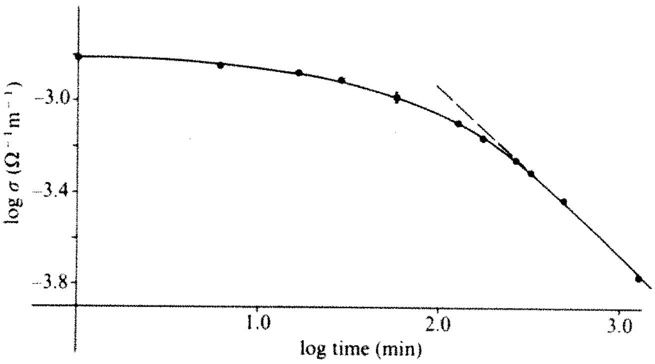

Fig. 3 Log conductivity as a function of log time for the same sample of ultramafic rock as that described in Fig. 2. The measurements of conductivity were made simultaneously with the velocity. Temperature, 250 °C; confining pressure, 0.35 GPa; pore pressure, 0.10 GPa.

A clear example of these effects are shown in Fig. 1, which depicts the first thermal cycle on a sample of ultramafic rock. While the sample was held at 250 °C there was an initial rapid increase in velocity with time ($\dot{V}_p \simeq 4 \times 10^{-4}$ km s^{-1}/min). The rate of increase in velocity, $\dot{V}_p$, decreased inversely with time so that after ~48 h a steady state maximum value of velocity was obtained. After the initial increase a linear relationship is suggested between the compressional wave velocity and log time (in min) (Fig. 2): $V_p \propto \log$ (time).

The results of the corresponding conductivity measurements are shown in Fig. 3. Lee *et al.* suggested that after the initial drop in conductivity (where uncertainty arises about the precise onset time): $\log \sigma \propto \log$ (time).

One might expect therefore a close relationship between the change in compressional wave velocity and the change in electrical conductivity. However, a direct comparison of these two parameters is unsatisfactory, due largely to the magnitude of the increase in velocity at the later stage of the transient effect being small compared to the observational error. In any case, Figs 2

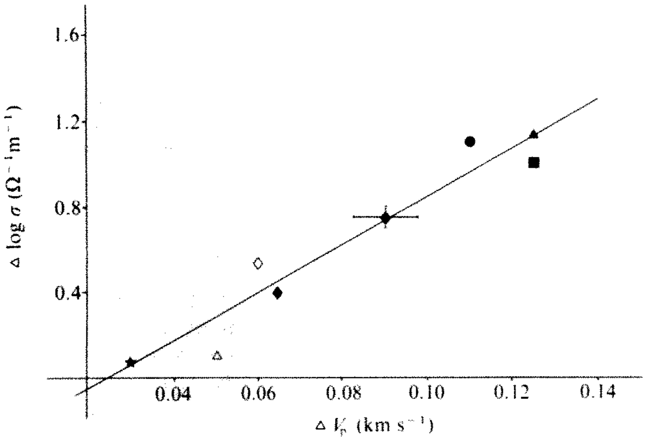

Fig. 4 Comparison of the magnitude of the transient compressional wave velocity and log conductivity effects over a period of 17 h for several rock types. Temperature, 250 °C; confining pressure, 0.30 GPa; pore pressure, 0.10 GPa; pore fluid, 0.5 M NaCl. ▲, Saturated granite; △, dry granite; ■, peridotite; ●, garnet mica schist; ◆, gabbro; ◇, gneiss; ★, quartzite.

and 3 suggest that the relationship may be more complex, in that the onset times of the linear segments are quite different for the two parameters. Comparison of the magnitude of the transient effect for several rock types and over a fixed time interval (Fig. 4) does show, however, a general relationship between the change in velocity and the change in (log) conductivity.

Spencer and Nur[2] suggested that the variation in velocity with time might be due to a solution of quartz in supercritical pore water. An increased content of silica in the pore fluid might increase the bulk modulus or viscosity of the fluid and hence the compressional velocity in the aggregate. However, increased silica content would also increase the electrical conductivity[6], whereas our observations of the transient effect associate increasing velocity with decreasing conductivity.

Lee *et al.*[1] suggested that the transient behaviour of electrical conductivity might be a sensitive indicator of a creep process. A primary creep[4] mechanism at these elevated temperatures and high effective pressures would result in the further closure of low aspect ratio microcracks, resulting in a significant drop in electrical conductivity[6]. It would also produce a marked decrease in compressibility of the sample[5] giving an increase in compressional wave velocity.

Our results lead us to believe that elevation of temperatures above 250 °C at a high effective pressure produces an irreversible process within the samples. This process must affect a large group of physical parameters and consequently be important in any discussion of experimental work when upper crustal conditions are simulated. In particular, measurements of temperature effects on conductivity and velocities should require a thorough thermal recycling study.

Nuclear magnetic resonance spectroscopy of humic materials

ALTHOUGH humic substances are some of the most important naturally occurring macromolecules in both soil and aqueous environments, their structures are still unknown. Our understanding of the components which comprise humic mixtures has been confined to the analysis of only minor portions (5–10%) of the total humic entity. It is, however, the whole humic aggregate, most of which is structurally unknown, which plays an active nutritional or transport role in nature. When the major fraction of humic matter, the alkali soluble substances, are studied, only poorly defined spectra have been obtained. Infrared, ^{1}H-NMR and ^{13}C-NMR spectroscopic techniques have yielded unresolved spectra in which little detail can be distinguished[1–5]. We report here that, using large magnetic fields and very high frequency (270 MHz) Fourier transform ^{1}H-NMR instrumentation, we have found that a wealth of detail can be obtained on the structure of humic solutions. A convolution difference method[6] allows discrete signals to be detected above the general broad band absorptions in much the same way as important structural and dynamic information concerning proteins has been gathered.

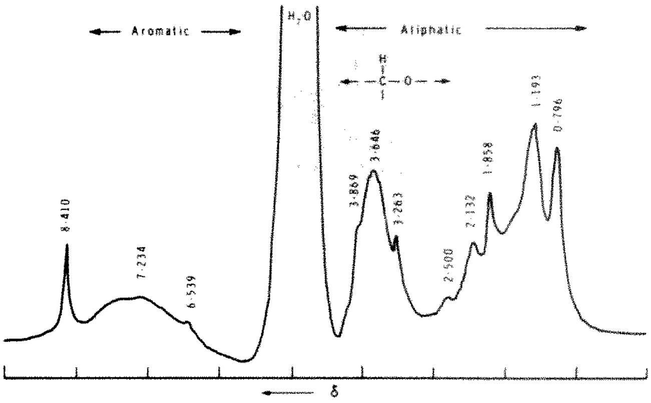

Fig. 1 270 MHz ^{1}H-NMR spectrum of Wakanui humic material in NaOH; chemical shifts are in p.p.m from internal TMS. They were measured with respect to external TMS and corrected. A pulse of 10 μs (85° tilt angle) was used to view a spectral window of 3.6 kHz in 8 K data points. Humic material was prepared by extraction of soil with 0.1 mol dm^{-3} NaOH. The mixture was acidified and the precipitate redissolved in NaOH for spectral examination.

The 270 MHz Fourier transform proton spectra of alkali soluble Wakanui silt loam (Wakanui silt loam—parent material—late Pleistocene loess imperfectly drained with seasonal high water table. pH = 5.8; C% 4.0, N% 0.35; C/N = 11.4, C.E.C. (me%) 23.4. New Zealand classification—yellow-grey earth) 'A' horizon material is shown in Fig. 1. The peak at 8.4δ arises from formate ion. This is confirmed by the signal at 167δ in the ^{13}C-NMR spectrum. From the integrated spectrum it is possible to estimate the fraction of protons, excluding exchangeable protons, which are aromatic (H^{*}_{ar}), and the fraction which is aliphatic (H^{*}_{ali}).

The Brown and Ladner equation[7], $f_a = [(C/H) - 0.5H^{*}_{ali}](C/H)^{-1}$, (where C/H is the carbon to hydrogen mol ratio), has been successfully applied to a range of carbonaceous mixtures for measuring the fraction of aromatic to total carbon (f_a) in the mixture. Recently, its basic assumption that the mol ratio of aliphatic hydrogen to aliphatic carbon is of the order of two, has been confirmed by ^{13}C-NMR spectroscopy[8]. ^{13}C-NMR spectroscopy of humic substances is still in its infancy[5] and when applied the Brown and Ladner assumptions may not be valid because of the predominance of COOH groups in humic substances. However, if f_a is redefined as f'_a, the fraction of aromatic carbon plus carboxylic carbon to total carbon, it becomes a useful parameter for describing the structure of humic substances.

Our results indicate that 65% of the carbon in Wakanui silt loam extract is aromatic and carboxylic acid carbon. The parameters f'_a and H^*_{ar} are 0.65 and 0.16 respectively. For moss peat soil, H^*_{ar} is around the same value but f'_a is much lower (0.50). This contrasts with a podsol 'A' horizon of $H^*_{ar} = 0.43$, $f'_a = 0.72$. Use of Brown and Ladner's parameters, σ, the degree of substitution, and H_{aru}/C_{ar}, the atomic hydrogen to carbon ratio of the hypothetically unsubstituted aromatic material is not justified because large amounts of oxygen-bonded aliphatic material are present in our extracts.

The combination of a low H^*_{ar} and high f'_a value recorded for loam extract, indicates that the solution contains aromatic material which is polycyclic or heavily substituted monocyclic. The presence of aromatic ^{1}H-NMR absorptions at >8.1 δ can be assigned to sterically hindered protons characteristic of many polycyclics. In our spectra they have only a very minor contribution to the total aromatic absorption.

From the combustion analysis, we were able to show that the mol ratio of hydrogen to nitrogen in this substrate is 12.4. In view of the known forms of nitrogen in humic materials[1], most of the nitrogen is probably bound to one or less protons. The contribution of nitrogen-bonded protons must then be $\leq 8\%$.

Of the rest, it seems from the absorptions around 3.6 δ that a large proportion (32%) of the aliphatic, or 27% of the total (excluding exchangeable) protons, is bound to carbon α to oxygen. The predominance of such aliphatic oxygen-bound carbon suggests a major proportion of sugar-like components or other polyhydroxy or polyether materials. This is supported by the ^{13}C-NMR spectrum (Fig. 2*c*) which also indicates COOH, aromatic and alkyl groups[5].

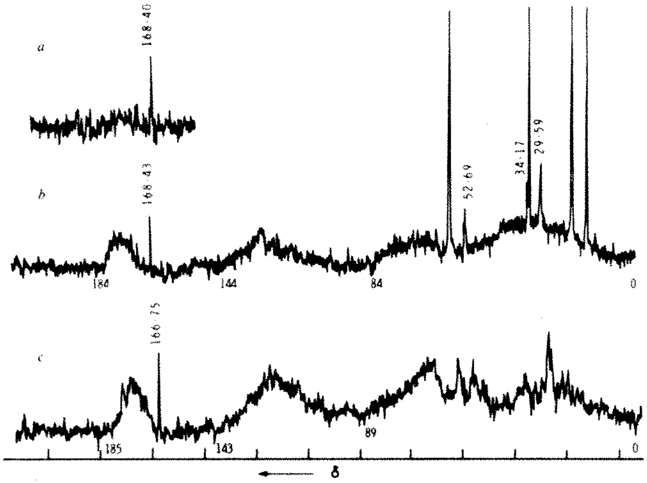

Fig. 2 ^{13}C NMR spectra of humic materials: *a*, Mangaroa humic acid peak at 168 δ; *b*, Mangaroa fulvic acid; *c*, Wakanui humic acid. Signals were observed relative to external TMS and corrected relative to internal TMS. Observed signals for Wakanui material were: 179.69, 184–169 (broad halfwidth = 9, δ_{max} = 177.06, COOH) 166.75 (strong), 143–106 (broad halfwidth = 17, δ_{max} = 127.02, aryl) 84–65 (broad halfwidth = 13, δ_{max} = 70.27, RZHCOZ, Z = R, H) 59.71, 59.3, 54.35, 35.80, 27.58 (strong, CH_2) 26.61, 22.6, 20.4. Observed signals for Mangaroa fulvic acid were 185–171 (broad, halfwidth = 8, δ_{max} = 181.24) 168.43 (strong), 144–104 (broad halfwidth = 10, δ_{max} = 128.82) 89–63 (broad, halfwidth = 16, δ_{max} = 74.54) 52.69 (strong), 34.17 (strong), 29.59 (strong) 55–8 (broad). 1-butanol peaks have not been listed. Spectra were recorded at 67.89 MHz with a 22 μs pulse (60° tilt angle). Acquisition time was 1.08 s for a 15 kHz spectral window in 32 K of memory and a delay of 1–2 s. Data were accumulated over 12 h.

Our spectra confirm the previous results[4,9–12] that alkyl chains make important contributions to humic substances. The signal at around 0.796 δ can be ascribed to CH_3 γ or further from aromatic rings. Polymethylene is present probably because of its low biodegradability[9].

In humic materials isolated from river sources, we observed the same general patterns although the $\mathrm{H{-}\overset{|}{\underset{|}{C}}{-}O{-}}$ absorptions were not as distinct, and protonated aromatic material represented only a very minor contribution. We were able to show by attenuation that the fine structure of the aromatic absorptions from both potable (Akatawara) and swamp water (Mangaroa) sources were very similar (see legend to Fig. 3 for a description of the waters). Application of a resolution-enhancement technique[6] which uses the difference between the broadened and resolved signals revealed detailed resonance information (Fig. 3). For example, Mangaroa humic acid isolated from a typical swamp water source in New Zealand showed at least six clear-cut aliphatic resonances which could be followed by, say, chemical modification of the humic material. Similarly, fine structure was found for samples from a potable (Akatawara) aqueous source.

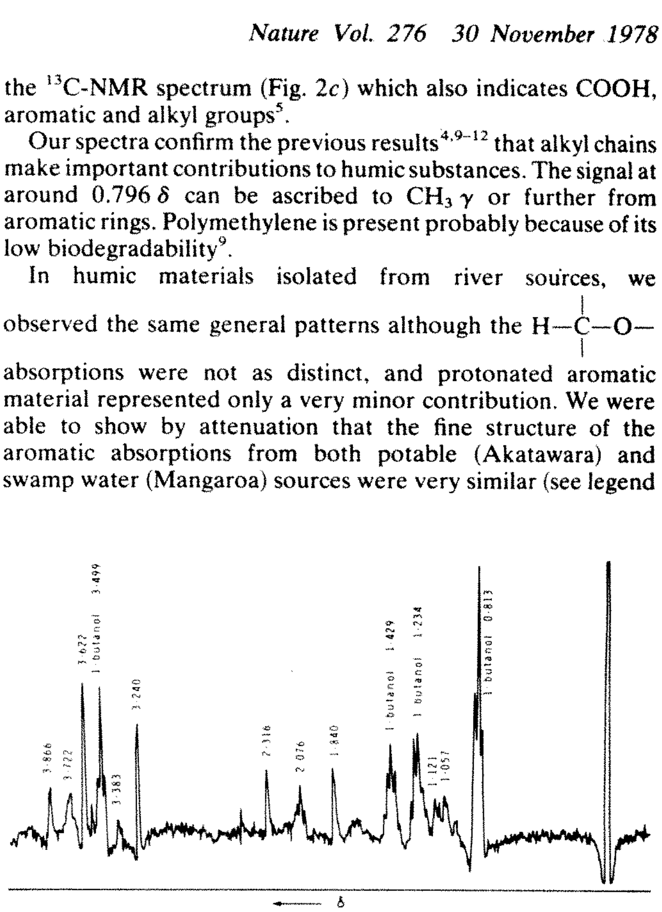

Fig. 3 Convolution difference spectrum of Mangaroa humic material. The signals due to 1-butanol arise from solvent tightly bound to the humic material which we were unable to remove on drying to constant weight. Samples were prepared by common water chemistry techniques[15] involving filtration, concentration, acidification and extraction of 1-butanol-soluble material. Mangaroa humic material: source—Black Creek, Mangaroa Valley, New Zealand. $pH = 6.5$; conductivity, 8.0 mS m^{-1}; absorbance, 0.990 at 270 nm; colour, 300 Hazen units. Akatawara humic material: source—Akatawara River. Upper Hutt, New Zealand (typical potable water). $pH = 6.9$; conductivity 7.1 mS m^{-1}; absorbance 0.210 at 270 nm; colour 40 Hazen units.

Our results agree with the increasing amount of evidence[4,5,9,13] that humic materials are not coal or lignin like in structure. The presence of large amounts of aliphatic polyhydroxy groups explains both the insolubility of humic materials in organic solvents and the behaviour of these substances to methylation[1,14]. Of particular interest is a methylated chloroform-soluble subfraction of a fulvic acid isolated by Schnitzer[10]; this has similar important absorptions around 3.6 δ. The subfraction has a number average molecular weight of 821 g mol^{-1} and possibly represents a small fragment of humic material of a type not unlike some of the macromolecules observed in our extracts. Some of the signals may not arise from methylation.

In contrast to other branches of environmental science, structural studies on soil and aqueous organic matter have always been hindered by a lack of available analytical tools. Our results reported briefly here show that at last this tool has arrived and that the next decade will see a great increase in studies using

NMR techniques which will throw new light on the chemistry of these elusive materials.

Desert varnish: evidence for cyclic deposition of manganese

WE have found evidence that desert-varnish coatings on rocks in the western US consist of micron-scale alternating dark and light layers that differ in manganese and iron content. We report here the first quantitative electron-microprobe analyses of desert varnish, that also show the chemical variations in these layers. In the field and laboratory we obtained new evidence that varnish covers a fresh substrate by nucleation of micron-sized patches that grow and coalesce.

Varnish-coated samples from Arizona, Utah and Idaho were studied in the field and in the laboratory. Host rocks include basalt, granite, quartzite, limestone, sandstone, caliche, quartz and opal. Varnish coatings range in thickness from a few micrometres to hundreds of micrometres, and characteristically are rich in manganese and iron[1-13]. Varnishes from widely separated localities have similar chemical, mineralogical, morphological and optical properties, and are compositionally independent of the host rock.

Ultra-thin (~10 μm) sections cut normal to the rock surfaces were prepared (by us and by R. Beauchamp). Sections from the three localities reveal alternating black and light-red layers that range in thickness from 0.25 to ≳20 μm (Fig. 1). The layers are typically a few micrometres thick. Mound-like or botryoidal structures are common, and within these structures the thicknesses of the layers are highly variable. Many layers can be traced laterally for at least several millimetres, except within the botyroidal structures where layers may extend for only tens of micrometres. Sections from single boulders show correlations between major layers in the varnish. Because of the difficulty of preparing ultra-thin sections (without losing the soft varnish) we have insufficient samples to say whether varnish layers can be correlated among samples on a local or regional scale.

Representative electron-microprobe analyses of varnish layers are given in Table 1. The areas analysed are shown in Fig. 1*a*. An analysis of the feldspathic matrix of the basalt substrate below the varnish is included in Table 1. Although it has long been known that desert varnish is rich in manganese[12,13] our data show that the manganese is concentrated in the optically opaque or dark layers (~20 wt% MnO_2) and that the adjacent red layers are relatively Mn-poor (~3 wt% MnO_2). The red layers are enriched in Fe_2O_3, SiO_2, Al_2O_3 and K_2O, whereas the dark layers contain more CaO. Other elements such as Ti, Mg, Na, P and S seem to be fairly evenly distributed throughout the coating.

In thin sections we can distinguish optically between the layered varnish and pockets of detrital material (Fig. 1*b*) consisting largely of clay with minor amounts of feldspar, quartz and hematite. The detritus typically makes up <30% of the coating. It occurs between botryoidal mounds where it seems to have been trapped by the growing varnish. In Fig. 2 the scanning electron microscope shows the botryoidal surface of the same varnish sample in Fig. 1. Figure 2 also shows random detrital minerals, and illustrates how grains can accumulate between the mound-like structures. These morphological relationships imply that analyses of scrapings of desert varnish include both layered varnish and trapped detritus.

The mineralogy of the varnish is not yet completely understood. Potter and Rossman[2-4] using scrapings of varnish from the Mohave Desert, California, concluded on the basis of mid-

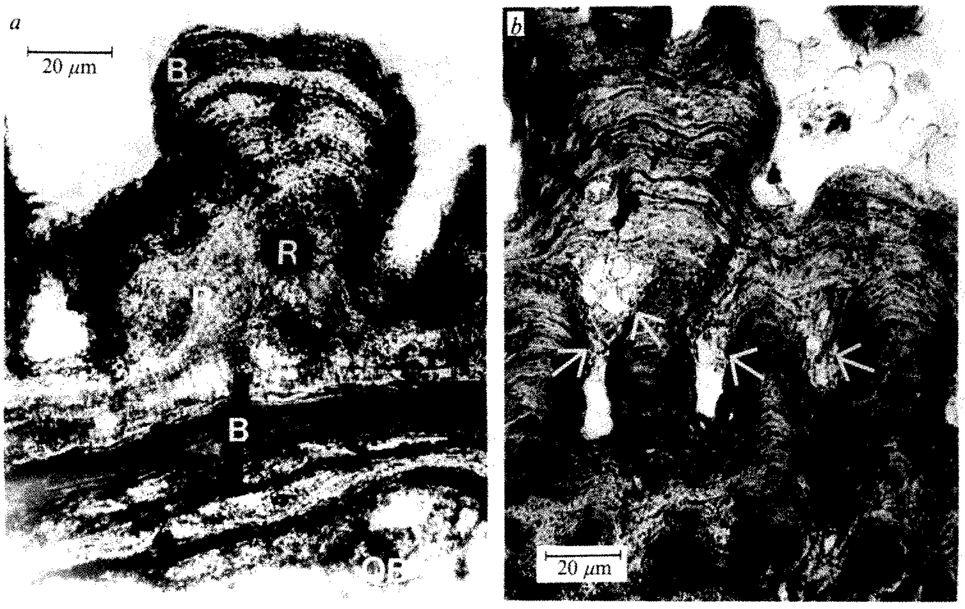

Fig. 1 *a*, Photomicrograph of Arizona desert varnish in a thin section cut normal to the surface of the sample. The varnish coats an olivine basalt (OB). Dark (black) (B) and light (red) (R) layers express mainly variations in Mn/Fe ratio (see Table 1) and imply alternating conditions of deposition. Mound-like structures are similar to those in Fig. 2. The closely spaced black bands at B are where electron microprobe analyses were made. (R) marks analyses representing an Mn-depleted and Fe-rich zone. The dark spot and lines are artefacts from the electron microprobe beam. Plane polarised light. *b*, Similar to (*a*) Arrows indicate pockets of detrital clays with minor feldspar, zeolite (?), quartz and hematite.

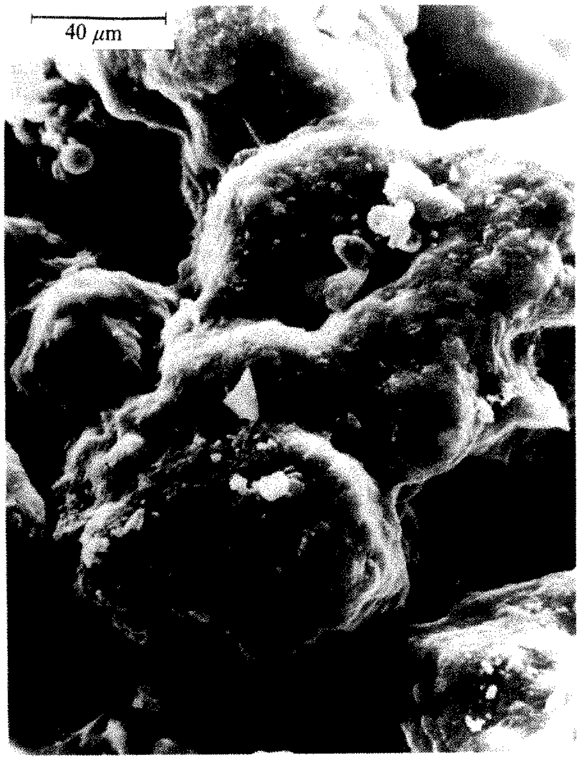

Fig. 2 Scanning electron micrograph of typical desert-varnish surface. Mound-like or botryoidal structures enlarge, coalesce, and are succeeded by new mounds as varnish accretes. Windblown-dust particles and microfloras visible on surface collect primarily in depressions, and become trapped in the varnish layer. Depressions may also shelter microorganisms. Cross-sections through a similar varnish surface are shown in Fig. 1.

IR spectroscopic measurements of chemical extracts that the main minerals are mixed-layer illite–montmorillonite clays with an intimate mixture of birnessite [(Na, Ca, K) $Mn_7O_{14} \cdot 3H_2O$] and hematite (Fe_2O_3). However, they found no X-ray powder-diffraction evidence for oxides. Our X-ray diffraction measurements also did not reveal definite peaks of oxides, and we agree with Potter and Rossman that any oxides present must be very fine grained (<0.1 μm). We found relatively strong peaks at ~12, ~10, ~4.50, ~3.36 and 2.57 Å, which may be caused by detrital clays, micas, feldspar quartz and so on, but which also are consistent with a possible Mn- and Fe-rich silicate mineral. We consider the present X-ray diffraction data ambiguous in veiw of the known heterogeneity of the scraped varnish samples.

Arizona soil	4.48% ± 0.13% H_2O (total)

* Sample from Fig. 1*a*, given in wt% oxide.

† Analysis is representative of feldspar-rich area below band areas 1–3.

‡ Fe computed as Fe_2O_3; Mn computed as MnO_2.

§ Analyses carried out on a DuPont moisture analyser by E. K. Gibson, Jr, at NASA Johnson Space Center. Samples were heated to 1,100 °C in a flowing stream of nitrogen. Released water was trapped on a P_2O_5 cell and removed by electrolytic conductance. Sensitive to 0.1 μg of water.

Thin sections show that the varnish layers consist of mineral plates orientated parallel to the layering. The plates range from submicron size to a few microns long, and have perfect basal cleavage. They are strongly pleochroic with α = golden yellow, $\beta = \gamma$ = deep reddish brown (~10-μm sections). Basal sections show $2V_\alpha \simeq 0°$. The refractive index in all orientations is >1.795. Microprobe analyses within large (2–3 μm) grains show them to be chemically homogeneous; however, the compositions of the grains vary from layer to layer, reflected in the analyses of Table 1. Thus, grains in dark layers are more strongly pleochroic and are more Mn-rich. We are not certain whether the grains are mixed phases (clays and oxides?) or whether they are a single silicate (unidentified) phase.

We interpret the layered botryoidal structures (Figs 1 and 2) as evidence that varnish grows vertically and laterally from nuclei in a manner similar to algal stromatolites. This conclusion is further supported by field evidence in Arizona where varnish is in all stages of re-covering spalls on boulders and outcrops of basalt. Old surfaces are completely covered with up to 200 μm of blue-black varnish, whereas surfaces of intermediate age show patchy coatings of lesser thickness. Field and laboratory observations indicate that freshly spalled surfaces are repopulated by microscopic black spots of varnish. Further addition of varnish occurs by enlargement of the spots which grow vertically and laterally. An analysis of one of these spots is given in Fig. 3. The spots progressively enlarge in size and number

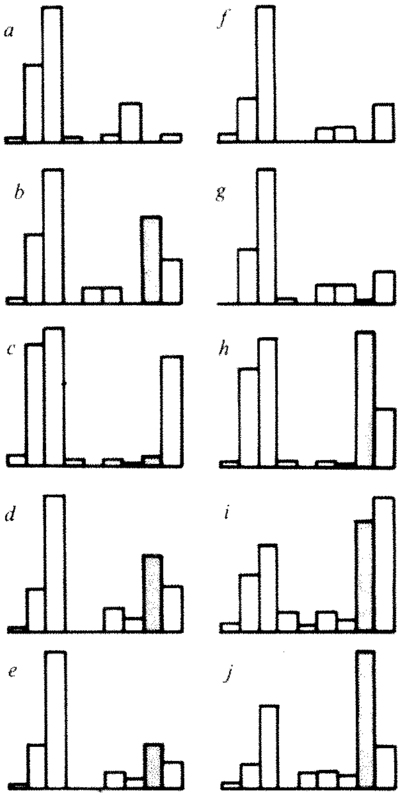

Fig. 3 SEM non-dispersive X-ray analyses (EDAX) of typical desert varnishes compared with aeolean dust, basalt substrate and a marine ferromanganese nodule. The red and black-band data* were approximated from Table 1. *a*, Arizona basalt substrate; *b*, varnish nucleation zone on Arizona basalt; *c*, Arizona varnish red band*; *d*, Idaho varnish; *e*, California varnish; *f*, Arizona soil near basalt; *g*, Arizona basalt surface outside varnish nucleation zone; *h*, Arizona varnish black band*; *i*, Utah varnish; *i*, marine manganese nodule.

until they coalesce and completely cover the substrate. Further thickening of the varnish occurs by continued nucleation and growth of spots (mounds) (Fig. 2). No evidence was found for the initial generation or growth of varnish as a uniform thin layer that simply increases in thickness with age.

The chemistry (Fig. 3), mineralogy and layered structure of varnish coatings from diverse localities and substrates are remarkably consistent, suggesting a common process of formation. We conclude from the lack of correlation between the composition of varnish and that of the substrate, and the presence of fine-grained dust on all sampled surfaces, that windblown dust is the source of the varnish materials. The preferential development of varnish on the tops of talus boulders is consistent with this view. This conclusion agrees with earlier suggestions[13] and with the results of Potter and Rossman[3,4].

Arizona varnish has concentrated manganese by 10^2–10^3 (Table 1, Fig. 3) relative to airborne dust that was collected in depressions on the tops of varnished talus boulders. If varnish is nourished by dust it implies not only an effective concentration mechanism, but also an efficient mechanism for the removal of large quantities of dust from which Mn and Fe have been extracted. The removal mechanism is probably rain and dew as is suggested by accumulations of soil in drip-evaporation deposits on the undersides of boulders that are perched above soil-level on talus piles. However, neither the mechanism for manganese (and iron) concentration nor the time-scale of the deposition is known. The repeated layering in the varnish implies that manganese deposition is favoured at certain times, followed by periods when less manganese is laid down. We propose that the cyclic concentration and deposition of MnO_2 are related to environmental changes, perhaps on a seasonal or annual basis, or on a longer time-scale separating periods when climatic conditions became optimum for varnish growth.

The highly effective mechanism for concentrating manganese, and the possibility of climatic control over the cyclic banding suggests (but does not prove) that a biological process may be involved in the formation of varnish[7,8,10,14]. The generation of varnish on rock by coalescence of growth centres is consistent with a biological process. We and J. Staley are studying the microorganisms that are associated with rock varnish. Cultures have been made in the field and in the laboratory of the surfaces and the interiors of varnishes. An assortment of bacteria, fungi and algae consistently occur on and within the varnish coatings, including at least one Bacillus that oxidises Mn^{2+} to Mn^{4+}. Further work is needed to determine whether organisms produce the varnish or merely live in it.

Knowledge of the processes responsible for the formation of desert varnish coatings may be useful in understanding present and ancient weathering environments, and in dating exposed surfaces[5,13,15]. The interpretation of optical remote-sensing data from satellites and aircraft must take into account the presence and significance of varnish in any attempt to map lithologies, as the coating locally masks the underlying rocks. If we can determine how varnish is deposited we may gain insight into the origin of remarkably similar layered deposits, namely freshwater and marine manganese nodules[16–21].

Mantle $^{40}Ar/^{36}Ar$ trapped in Cretaceous deep-sea basalts

THE abundance and isotopic composition of rare gas in the mantle provides an important constraint on the origin and evolution of the Earth's atmosphere. One of sources of such information is basalts which erupted from ocean ridges. Ozima[1] stated that a high $^{40}Ar/^{36}Ar$ ratio in the mantle suggests sudden degassing at an early stage of the Earth's evolution. Several authors[2,3] have reported excess ^{40}Ar and high $^{40}Ar/^{36}Ar$ ratios in rapidly quenched rims of young deep-sea basalts. However, the Ar composition in old ridge basalts was not known. We report here a measurement of the isotopic composition of Ar in old deep-sea basalts. The Glomar Challenger drilled a Cretaceous ocean floor near the southern end of the Bermuda Rise in Deep Sea Drilling Project[4]. The drilled site (Site 417) is on the magnetic anomaly MO which has been estimated to be 108 Myr old.

The samples used were pillow basalts from Hole 417D, which contained only limited alteration minerals and had widespread fresh glass[4,5]. Glassy rims of the Cretaceous pillow basalt cores, designated 22-3/24-27, 28-5/85-92, and 29-6/95-104, were investigated for rare-gas composition. (Detailed results will be published elsewhere.) The concentration and isotopic ratio of Ar are given in Table 1. The potassium content in the basaltic

* Corrected for radiogenic ^{40}Ar produced in basaltic glass for 108 Myr.

0028-0836/78/0276—0491$01 00

glass has been determined to be 0.083, 0.091 and 0.075% for cores 22-3/24-27, 28-5/85-92 and 29-6/95-104, respectively (T. Ui, H. Haramura & H. Nagai, unpublished data). The radiogenic ^{40}Ar produced in basaltic glass during the past 108 Myr was corrected on the basis of the potassium content given above. The ^{40}Ar/^{36}Ar ratios corrected for radiogenic ^{40}Ar are also given in Table 1.

On the model that a given mantle component of Ar in the basalt mixed with varied amounts of contaminating atmospheric Ar, a plot of ^{40}Ar/^{36}Ar against 1/^{36}Ar gives a straight line,

$$({}^{40}\mathrm{Ar}^*/{}^{36}\mathrm{Ar})_{\mathrm{meas}} = S/({}^{36}\mathrm{Ar})_{\mathrm{meas}} + ({}^{40}\mathrm{Ar}/{}^{36}\mathrm{Ar})_{\mathrm{contam}} \qquad (1)$$

where ^{40}Ar*/^{36}Ar is the ratio corrected for radiogenic ^{40}Ar, and

$$S = ({}^{36}\mathrm{Ar})_{\mathrm{mantle}}[({}^{40}\mathrm{Ar}/{}^{36}\mathrm{Ar})_{\mathrm{mantle}} - ({}^{40}\mathrm{Ar}/{}^{36}\mathrm{Ar})_{\mathrm{contam}}] \qquad (2)$$

if the concentrations of mantle ^{36}Ar and ^{40}Ar are uniform in the samples investigated (see Fig. 1). To evaluate the amount of mantle ^{40}Ar and the ^{40}Ar/^{36}Ar ratio of mantle Ar trapped in the Cretaceous basaltic glass, the ^{40}Ar/^{36}Ar isotopic ratio for contaminating Ar and the concentration of mantle ^{36}Ar should be known.

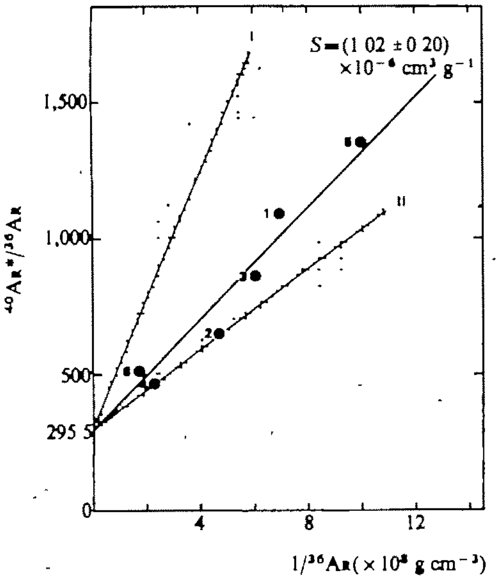

Fig. 1 A plot of ^{40}Ar*/^{36}Ar against 1/^{36}Ar. ^{40}Ar*/^{36}Ar ratios are corrected for radiogenic ^{40}Ar produced in basaltic glass by decay of ^{40}K for 108 Myr. The isotopic ratio of contaminating Ar was assumed to be atmospheric (see text). For comparison, correlation lines I and II given by Dymond and Hogan[8] are also plotted. ●, This work.

Microscopic examination of thin sections of the same cores used in this work (T. Ui, personal communication), shows that cores 22 and 29 have many cracks in the glassy rims along which alteration of glass is advanced. Gas pores have been filled with altered materials. For core 28, the alteration is so advanced that fresh glass is a minor component, and large cracks have been filled with altered materials such as carbonate, clay and zeolite. Thus the alteration in these cores is likely to be due to seawater–rock interaction at low temperature[5]. Hence the contamination of Ar can be attributed to penetration of seawater into the altered materials. Seawater which is in equilibrium with the atmosphere contains a large amount of atmospheric Ar (10^{-4} cm^3 STP g^{-1}) (ref. 6). Owing to a high diffusion rate of Ar in water, Ar in the altered materials could be replaced by Ar with the modern ^{40}Ar/^{36}Ar ratio.

Another possibility is contamination by seawater Ar at the time of eruption through the Ar diffusion into the quenching glassy rim of pillow basalt. In this case, $(^{40}\mathrm{Ar}/^{36}\mathrm{Ar})_{\mathrm{contam}}$ may be different from that of atmospheric Ar and represent the isotopic ratio of Ar in Cretaceous seawater. However, experimental evidence for ^{3}He and ^{40}Ar excesses in glassy rims of modern pillow basalts[2,3,7], indicates that the inherent rare gases in lava were compressed tightly in the rapidly quenched rims of pillow basalts under great hydrostatic pressure and the interaction with seawater was not appreciable in the rare-gas composition. Thus we presume that the contribution from the latter process is ineffective compared with the contamination of atmospheric Ar by the penetration of modern seawater into the altered materials. A least-squares fit gives an intercept of $(^{40}\mathrm{Ar}/^{36}\mathrm{Ar})_{\mathrm{contam}}$ equal to 243±73 without any assumption on the isotopic ratio of contaminating Ar. This value is consistent with that for atmospheric Ar (=295.5) within experimental error. In the following discussion, therefore, we use the atmospheric ^{40}Ar/^{36}Ar ratio as the isotopic composition of contaminating Ar.

Figure 1 plots ^{40}Ar/^{36}Ar against 1/^{36}Ar with the intercept of 295.5 for the Cretaceous deep-sea basalts. It defines a correlation line the slope of which is $(1.02 \pm 0.20) \times 10^{-6}$ cm^3 STP g^{-1}. For comparison, correlation lines for modern deep-sea basalts given by Dymond and Hogan[8] are also plotted. As mentioned earlier, the amount of mantle ^{40}Ar and the ^{40}Ar/^{36}Ar ratio of mantle Ar trapped in the Cretaceous basaltic glass depend on the concentration of mantle ^{36}Ar. We use the lowest concentration of ^{36}Ar measured in sample 5 as an upper limit of mantle ^{36}Ar. From equation (2) with this value, $(^{40}\mathrm{Ar}/^{36}\mathrm{Ar})_{\mathrm{contam}} = 295.5$, and $S = 1.02 \times 10^{-6}$ cm^3 STP g^{-1}, we have

$$1.02 \times 10^{-6} < ({}^{40}\mathrm{Ar})_{\mathrm{mantle}} \leq 1.31 \times 10^{-6}\ \mathrm{cm^3\ STP\ g^{-1}}$$

and

$$({}^{40}\mathrm{Ar}/{}^{36}\mathrm{Ar})_{\mathrm{mantle}} \geq 1{,}350$$

as a lower limit of the ^{40}Ar/^{36}Ar ratio of mantle Ar trapped in the Cretaceous deep-sea basalts. For mantle ^{36}Ar trapped in glass of modern deep-sea basalts, Craig and Lupton[9] have adopted 0.5×10^{-9} cm^3 STP g^{-1}. With this value, we have $(^{40}\mathrm{Ar})_{\mathrm{mantle}} = 1.17 \times 10^{-6}$ cm^3 STP g^{-1}, and $(^{40}\mathrm{Ar}/^{36}\mathrm{Ar})_{\mathrm{mantle}} = 2{,}340$ in the Cretaceous deep-sea basalt glass.

In conclusion, a linear correlation in the ^{40}Ar/^{36}Ar against 1/^{36}Ar plot indicates that Ar in the Cretaceous basaltic glass is a mixture between a uniform concentration of mantle Ar and varied amounts of contaminating atmospheric Ar. The ^{40}Ar/^{36}Ar ratio of mantle Ar trapped in the Cretaceous basaltic glass is >1,350, and the amount of mantle ^{40}Ar resembles that trapped in modern basaltic glass[10,11].

We thank Professor M. Ozima, University of Tokyo, for valuable comments and Dr T. Ui, Kobe University, for use of unpublished data on the potassium content and on the microscopic examination of thin sections.

Evolution of sulphur dioxide tolerance in perennial ryegrass

THE combustion of fossil fuels for domestic and industrial purposes, coupled with rapid industrial growth over the past 150 years, has resulted in sulphur dioxide becoming an integral part of the environment. Extensive research into the effects of sulphur dioxide on vegetation began in the 1920s, but the possibility of evolution of tolerance has only recently received attention, in spite of the implications of this for the overall effect of SO_2 in the field. We present here data that provide strong evidence for the evolution of SO_2 tolerance in a perennial ryegrass population from an urban area of Merseyside, UK.

Any environmental factor that has an adverse effect on plant growth may exert selection pressure on plant populations by acting on their inherent genetic variability, thus causing major changes in gene frequency within a few years[1]. Recent research has shown the detrimental effect of SO_2 on perennial ryegrass (*Lolium perenne* L.) and the existence of substantial genetic variability in response[2,3]. Such variation in response in the field could result in the elimination of susceptible individuals from natural ryegrass populations, thus causing an increase in the overall tolerance of these populations. Indeed, the indigenous ryegrass at Helmshore (24 km north of Manchester) seems to have evolved tolerance to sulphur dioxide. The observations at Helmshore, however, were based on the response of two ryegrass clones—selected as sulphur dioxide tolerant in field trials at Helmshore—compared with many individuals of the S23 cultivar grown from seed.

To investigate overall population responses and variability in genotype response to sulphur dioxide, we have examined two long-established perennial ryegrass populations from Merseyside. These have experienced widely different ambient sulphur dioxide concentrations[4], but the climate, soil and management conditions have been comparable, because they were collected from parklands similar in aspect, altitude and soil.

One population was collected from Newsham in the centre of Liverpool and the other from West Kirby, a rural area on the Wirral peninsula 16 km WSW of Liverpool. Records show that typical winter mean concentrations of SO_2 in the centre of Liverpool[4] between the late 1950s and the early 1960s were 600–700 $\mu g\ m^{-3}$. Since that time, the winter concentrations have decreased to approximately 200 $\mu g\ m^{-3}$. In rural areas of the Wirral however, concentrations have been much lower, decreasing from approximately 80 $\mu g\ m^{-3}$ in the early 1960s to 30–40 $\mu g\ m^{-3}$ at present.

Table 1 Response of two perennial ryegrass populations from Merseyside to sulphur dioxide

	Control ($35\ \mu g\ m^{-3}$)	Polluted ($650\ \mu g\ m^{-3}$)
(*a*) Living dry matter		
Newsham (high SO_2 area)	0.91	0.82
West Kirby (low SO_2 area)	0.90	0.64
$P < 0.05$ LSD between populations = 0.08		
LSD between treatments = 0.14		
(*b*) Total (living + dead) dry matter		
Newsham	1.18	1.18
West Kirby	1.19	1.00
$P < 0.05$ LSD between populations = 0.10		
LSD between treatments = 0.19		

Values are mean shoot dry weight (g per clone). Plants were grown under a 16 h day/8 h night cycle under a light intensity of 30 $W\ m^{-2}$. Day and night temperatures were maintained at 20 ±1°C, and 14 ±1°C respectively. Relative humidity was kept above 60%. Wind speed over the plants was 120 $m\ min^{-1}$. The results are the mean shoot dry weights of two sequential experimental runs with identical sets of clones carried out in the same fumigation conditions.

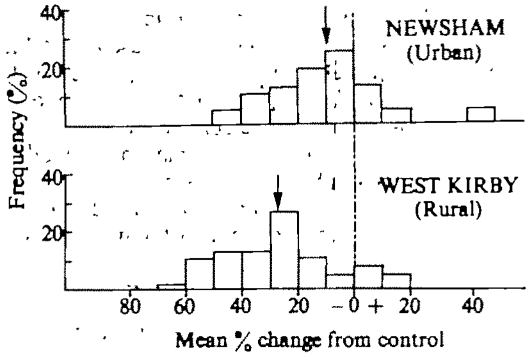

Fig. 1 Differential response to SO_2 of urban and rural ryegrass populations. Change from control measured as weight of living dry matter grown in SO_2 polluted air. Arrows mark arithmetic means of the frequency histograms.

Thirty-six individually identified clones of each population were exposed to 35 $\mu g\ SO_2\ m^{-3}$ (control) or 650 $\mu g\ m^{-3}$ (polluted) for 8 weeks in a wind-tunnel fumigation system (Table 1). In control air the mean yields of both populations were comparable. However, in the polluted air the West Kirby population showed a significant reduction in yield, whereas no significant reduction was shown by the Newsham population. Analyses of variance for both the living and total dry matter showed that there was a significant ($P < 0.01$) interaction between sulphur dioxide and the populations. Interestingly, the reduction in yield of total dry matter was less than that for living dry matter only. This suggests that the higher sulphur dioxide concentration caused an increase in the rate of senescence as well as 'invisible injury' (that is, reduction in yield without visible symptoms).

The percentage change in the living dry matter of each individual clone, as a result of the sulphur dioxide fumigation (Fig. 1), shows a wide range of genotypic variability within each population. In addition to the differential response of the populations to sulphur dioxide, the histograms reveal a reduced clonal variability within the Newsham population, presumably due to selection of the more tolerant genotypes by sulphur dioxide in the field.

These results provide strong evidence that the high sulphur dioxide concentrations prevalent in urban areas of Merseyside until the early 1960s have acted as a selective force. Furthermore, this population differentiation has persisted even though sulphur dioxide concentrations have decreased appreciably since then.

It is, therefore, important that the evolution of sulphur dioxide tolerance is taken into account when attempts are made to estimate reductions of yield in the field by extrapolation from laboratory studies. Fumigation of spaced plants in laboratory experiments may well overestimate the effects of sulphur dioxide on plant populations, as there can be no compensation for the yield reduction of sensitive individuals by the increased growth of tolerant individuals in these experiments, as would occur in dense swards. If the evolution of tolerance were sufficiently rapid in young grass swards then overall productivity would suffer only a temporary reduction, provided that the more tolerant individuals were of comparable vigour to the more susceptible. This seems likely, for in our results the yields of the two populations were similar in control treatments. Unfortunately, little is known about the rate of evolution of sulphur dioxide tolerance, although it is known that evolution of metal tolerance can occur within a few years.

In the field, plants are often exposed to mixtures of air pollutants, and the yields of some pasture grasses can be reduced severely by the synergistic interaction of sulphur dioxide and nitrogen dioxide[5]. It is thus possible that some plant populations could have evolved tolerance to combinations of air pollutants as well as to a single pollutant.

0028-0836/78/0276—0493$01 00

The potential for evolutionary adaptation to sulphur dioxide depends on the existence of genetically based variability in response within the population, variety or species. Such variability would be less in inbred agricultural crop varieties: also it is unlikely that substantial genetic change would occur in any crop, however variable, that was replaced annually from material bred in a low sulphur dioxide area.

Rhizobium japonicum mutants unable to use hydrogen

FACTORS which limit nitrogen fixation by the legume nodule symbiosis may be environmental (such as illumination, water or CO_2 supply), or intrinsic (such as supply of photosynthate to the nodule[1], effectiveness of rhizobial strain). An important intrinsic feature seems to be ATP-dependent hydrogen evolution by nitrogenase, which leads to loss of energy that would otherwise be available for nitrogen fixation[2]. Some strains of *Rhizobium japonicum* possess a unidirectional hydrogenase, capable of hydrogen oxidation but not hydrogen evolution, which recycles the hydrogen evolved by nitrogenase, regenerating ATP as well as protecting the nitrogenase from oxidative damage[3–5]. The physiological importance of hydrogenase in this context, with its obvious implications for agriculture, has so far been deduced from studies on naturally occurring strains possessing or lacking hydrogenase[2,6]. A more accurate assessment requires the isolation of isogeneic hydrogen uptake-negative (Hup^-) mutants from hydrogenase-positive (Hup^+) parents, and their comparison in physiological and agronomic studies. Such mutants would also be valuable for gene transfer and biochemical studies. We now report the isolation of Hup^- mutants.

Table 1 Effect of phenazine methosulphate on viability of bacteroids

Conditions	No. of survivors	% Kill
No PMS, N_2 atmosphere	4.2×10^9	—
PMS, N_2 atmosphere	2.8×10^9	23%
PMS, H_2 atmosphere	6.0×10^8	86%

A bacteroid suspension of strain USDA DES 122 from fresh soybean nodules was divided among test tubes sealed with serum stoppers and then flushed with the appropriate gas. Phenazine methosulphate (1 mM) was added, and the suspension incubated at 26 °C in the dark. After reduction of the dye (5 min), the atmosphere was replaced with O_2 and the suspension was rapidly mixed under normal laboratory illumination Cells were centrifuged, resuspended and plated for survivor counts. The number of survivors reported is the average of two separate experiments. The bacteroid suspensions consisted of 2.0 mg dry weight bacteroids in 0.4 ml of Mg-phosphate buffer (50 mM K_2HPO_4, 2.5 mM $MgCl_2$, pH 7.0) and were prepared as described elsewhere[15], except that the bacteroids were washed twice in the Mg-phosphate buffer

Our strategy was to seek a substrate for hydrogenase whose product on reduction was, or could be made, toxic. Survivors resistant to such toxicity ought to include Hup^- phenotypes. 'Phenazine methosulphate' (N-methylphenazinium methyl sulphate, PMS) proved to be a good substrate for rhizobial hydrogenase[4] and was reduced faster by bacteroid suspensions in the presence of H_2 than in its absence. In pilot experiments with *Azotobacter vinelandii*, photo-oxidation of PMS reduced in H_2 by bacteria killed some 90% of the cells; we therefore devised the procedure in Table 1, in which suspensions of largely viable[7] bacteroids were allowed to reduce PMS and immediately treated with pure O_2; enhanced killing in the presence of H_2 was then observed. The reason for the lethal effect of oxidising reduced PMS is not clear; it may involve H_2O_2 formation[8], a damaging effect of a free-radical derivative of PMS[9] or localised generation of the antibiotic pyocyanine from PMS.

Survivors of the PMS-treated population were then screened by the triphenyl tetrazolium procedure reported from this laboratory[10]. To be confident that presumptive mutants were not random contaminants, it was necessary to label genetically the strain treated, and so a parent strain (SR) was prepared: a spontaneous streptomycin (Str, 250 μg ml^{-1})-resistant followed by kanamycin (Kan 50 μg ml^{-1})-resistant double mutant of strain USDA DES 122. This strain showed effectiveness, hydrogenase content and nodulation capacity comparable to DES 122 and retained the Kan and Str markers when re-isolated from nodules.

Table 2 H_2 evolution, C_2H_2 reduction, nodule weight and number of nodules formed by strain SR and derivative mutants of *R. japonicum*

Strain	H_2 evolution (μmol per h per g nodule wt)	C_2H_4 formed (μmol per h per g nodule wt)	Nodule weight (mg per plant)	No. of nodules per plant
SR	<0.005	73.9±2.3	193±14	27±2
SR1	24.8±2.4	54.6±3.4	162±19	23±5
SR2	18 5±1.9	46.9±2.3	243±22	27±3
SR3	24.0±2.9	56.4±7.0	217±18	22±3

Results are means ±s.e.m. for three 25-d-old Wilkin soybeans grown in Leonard jars in the greenhouse, as described elsewhere[11,12]. At the time of planting, each seedling was inoculated with approximately 1×10^9 cells. Nodulated roots were placed into 30-ml serum vials, the vials were sealed and incubated for 15 min at 26 °C, and 0.5-ml samples removed for H_2 quantitation by gas chromatography. After removal of the H_2 sample, 3 ml of C_2H_2 was injected into the vial, and 0.5-ml gas samples were removed at 15 min and 30 min for C_2H_4 quantification by gas chromatography.

For PMS treatment, nodules produced by this strain were picked from 4-week-old soybean plants (cv. Wilkin) grown in Leonard jars[11,12], and bacteroids were obtained as described in the legend to Table 1. The conditions of PMS treatment were also as described in the Table 1 legend, except that the suspensions contained 2.4 mg bacteroids. Survivors of the PMS killing procedure were plated on to a medium previously described[13], but also containing gluconate 5 g l^{-1}, arabinose 5 g l^{-1}, triphenyl tetrazolium chloride 0.1 g l^{-1} and streptomycin 250 μg ml^{-1}. Approximately 1.7×10^4 colonies formed by individual survivors of the PMS treatment were screened for tetrazolium reduction. Those colonies exhibiting low dye-reduction ability after 10 d of growth were chosen and restreaked on to the tetrazolium-containing medium. The isolates consistently showing poor dye-reduction ability were each inoculated on to two soybean plants in cellophan growth pouches[14]. After 3 weeks of growth the roots from each pouch

Table 3 H_2 and O_2 uptake by bacteroids and free-living cultures of strain SR and mutant strains SR1, SR2, SR3

Strain	Bacteroids		Free-living cells	
	H_2 uptake*	O_2 uptake*	H_2 uptake†	O_2 uptake†
SR	3.7	0.70	119	230
SR1	<0.005	0.64	<0.005	276
SR2	<0.005	0.71	<0.005	240
SR3	<0.005	0.82	<0 005	253

* Expressed as μmol per h per mg protein. Nodules from 28-d-old Wilkin soybean plants were collected and the bacteroid fraction isolated in aerobic conditions as described in the legend to Table 1. Bacteroid suspensions containing approximately 1.5 mg protein per ml in Mg-phosphate buffer were assayed for uptake of H_2 and O_2 at initially saturating levels[11] by use of an amperometric method that used a Clark-type electrode[16]. Rates of O_2 uptake were determined in the absence of H_2.

† Expressed as nmol per h per 10^8 cells. Cells were grown for 5 d on a medium designed for expression of hydrogenase[10], suspended in Mg-phosphate buffer, and O_2 and H_2 uptake rates determined amperometrically. All suspensions contained $1.1–1.2 \times 10^8$ cells per ml. Rates of O_2 uptake were determined in the absence of H_2.

were removed from the plants, and the nodulated root system was assayed for H_2 evolution by gas chromatography. Nodules lacking hydrogenase are not able to recycle H_2 produced by nitrogenase, so Hup^- mutants would evolve H_2.

Three mutants which produced nodules evolving H_2 were obtained, SR1, SR2 and SR3; strain SR evolved no H_2 (Table 2). The three mutants did not differ greatly from the wild type in symbiotic characteristics other than the ability to use H_2 (Table 2). Nodule weight and number of nodules formed per plant for SR2 and SR3, were not appreciably different from the corresponding values for SR. Apparently, their lack of ability to use H_2 did not greatly impair their other symbiotic properties. Mutant SR1, however, showed less nodule weight than SR, SR2 and SR3. Strain SR apparently formed nodules containing greater nitrogenase activity than any of the mutants (Table 2, and other data not shown); this greater nitrogenase activity may be due to the ability of strain SR to recycle H_2. The Hup^- phenotype of the mutants was retained on re-isolation from nodules, together with the Kan and Str markers; hence, the Hup^- mutations were reasonably stable. Free-living cultures were grown in the conditions previously reported[10] which allow expression of Hup^+ *ex planta*, and were tested for H_2 and O_2 uptake rates by the amperometric method[11,16]. Bacteroid suspensions were also tested. Suspensions of strain SR took up H_2 but none of the mutants did so (Table 3). Free-living cultures of the mutants as well as bacteroids isolated from nodules showed O_2 uptake rates comparable to that of strain SR (Table 3), indicating that the mutant strains still carry out normal O_2-linked respiration.

Three mutants obtained by screening 1.7×10^4 survivors of the PMS treatment is rather a high proportion, so the possibility exists that the PMS procedure is mutagenic. We found that the PMS procedure approximately doubled the frequency of streptomycin-resistant isolates (from bacteroids of *R. japonicum* strain USDA DES 122) compared to untreated controls; some possibility therefore remains that the mutants contain additional lesions in loci other than in the H_2-uptake system. It has not so far been practicable to check by conventional reversion tests whether the Hup^- strains are point mutations.

Greenhouse and field tests of these mutants are in progress to assess the agronomical importance of hydrogenase, and their specific biochemical defects will be investigated to aid understanding of the biochemistry and physiology of the H_2-uptake system in the *Rhizobium*-legume symbiosis.

The technical assistance of Joe Hanus is appreciated; Frank Simpson participated in tests of PMS with *A. vinelandii*. This research was supported in part by NSF grant PCM 77-08784 awarded to H. J. E. and the Oregon Agricultural Experiment Station from which this is Paper No. 4946. R. J. M. thanks the Rockefeller Foundation for a post-doctoral fellowship, J. R. P. was supported by the grant GAAS-7628 from the Rockefeller Foundation.

Kinship asymmetry in diploids

THE relatedness of one individual to another is an important variable in kin selection theory. An unusual property of relatedness is its asymmetry. For haplo-diploids, this asymmetry has been discussed[1]. We show here that, surprisingly, there may also be asymmetry in relatedness between two diploids. One may in fact be more related to a person than they are to you.

The easiest way to see this is to consider a single locus, where the genotypes of two individuals are known. Possible pairs of genotypes that the individuals may have are shown in Table 1. When one individual is homozygous, and the other heterozygous with one of its alleles common to both individuals, relatedness is not reciprocal. An individual A with genotype *ww* is related to an individual B with genotype *wx* by a half, but B is related to A by one. Note that B can increase the representation of its alleles more in the next generation by aiding A than A can by aiding B.

This asymmetry in relatedness of diploids follows from the concept of relatedness as applied to cases of inbreeding[2]. A

Table 1 Relatedness of A to B and B to A

Genotypes		Relatedness	
A	B	A to B	B to A
ww	*ww*	1	1
ww	*wx*	½	1
wx	*ww*	1	½
wx	*wx*	1	1
wx	*wy*	½	½
wx	*yz*	0	0
wx	*yy*	0	0
ww	*yz*	0	0
ww	*yy*	0	0

statement of relatedness, valid for diploids and haplodiploids alike is that the relatedness of A to B is a ratio of averages: the average, over alleles in A, of the probabilities that each will be found in a random gamete of B, divided by the average, over alleles in A, that each will be found in a random gamete of A.

In the usual kin selection analysis, one does not deal with the certainty of known genotypes, but rather with the overall expected relatedness (for example, expected frequencies of genotype pairs) that two individuals may have as the result of some pedigree relationship. Consideration of expected relatedness for diploids also gives non-reciprocal relatedness whenever there is some inbreeding and the two individuals are not identically inbred[2,10].

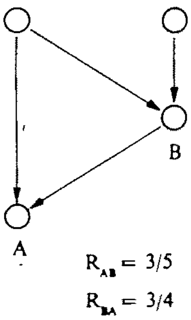

Fig. 1 Parent–offspring mating and relatedness

As it is unlikely that mating in natural populations is uniform and symmetric, non-reciprocal relatedness will be common. Simple pedigrees that have the property of non-reciprocal relatedness are brother–sister mating followed by one of the sibs outbreeding, or parent–offspring mating. A pedigree diagram for the latter case is shown in Fig. 1. Relatedness values are given as calculated from Hamilton's expression[2]. Both of these simple pedigrees occur in natural populations; for example, they are thought likely in wolves[3].

There is more asymmetry in relatedness if there is more inbreeding before the outbreeding. At the extreme limit, when inbreeding has reached essential homozygosity, offspring produced by outbreeding would be related to their inbred half-sibs by one; relatedness of the inbred individuals to their outbred half-sibs would be a half.

Although there is substantial literature on problems of calculating relatedness[2,4,5], non-reciprocal relatedness of diploids has escaped notice. Perhaps this is because the idea conflicts with everyday usage of the word.

Kin selection theory uses relatedness in proposing answers to two sorts of questions. One question concerns how an optimal strategist should act when faced with a choice of aiding or not aiding other individuals. The other question concerns the expected change in allelic frequency of an allele that has indirect effects on the fitness of individuals other than the allele's bearer. Non-reciprocal relatedness affects the answers to both questions but the implications for optimal strategy decisions seem the most interesting.

For haplo–diploid organisms, asymmetrical relatedness has recently been in the centre of attempts to test strategy aspects of kin selection theory[6–8]. In the diploid–diploid case, recognition of non-reciprocal relatedness might lead to testable predictions about interactions between individuals.

A major unresolved aspect of kin selection theory is the degree to which kin selection has actually resulted in effects on the evolution of phenotypes. Many aspects of behaviour and social structure have been interpreted under the kin selection paradigm. However, the theory is rather flexible, and it is easy to bend it to fit the sparse data available.

Perhaps the consequences of non-reciprocal relatedness are trivial and the magnitude or predictability of this asymmetry falls below the as yet unknown threshold for the evolution of strategies to take it into account. It is not yet clear what magnitudes of relatedness can influence the evolution of phenotypes. Empirical studies will be necessary to resolve this. Successful empirical testing requires awareness of the subtleties of relatedness if it is to succeed in establishing the domain of validity of kin selection theory. Pending such tests, I agree with Williams[9] that adaptation, particularly such 'fine-tuned' adaptation should not be assumed. The burden of proof lies with those who claim the adaptive significance of this or any phenomenon.

Communal breeding in green woodhoopoes as a case for reciprocity

RECIPROCITY[1], or reciprocal altruism[2], and kin selection[3] are concepts basic to sociobiology. Although both theories have been widely accepted[4], little critical evidence exists for either[5,6]. Communal, or cooperatively breeding, birds are important organisms for testing these theories because nonbreeding helpers regularly provide aid to nestlings, such as food and protection. Helpers are often related to the nestlings they aid, frequently being older siblings[7,8], leading some authors to conclude that kin selection is the evolutionary basis for the apparent altruism seen in cooperative breeders[8,9]. However, the possible influence of other, individual strategies has not been completely separated from kin selection for any communal bird; this would require elimination of kinship ties as a variable[5]. Aid by a helper to an unrelated young bird must either be considered an 'accident' or it suggests that factors other than, or in addition to, kin selection might be the evolutionary bases for helping behaviour, at least in that particular species. Here we report information on a tropical, communal bird, the green woodhoopoe (*Phoeniculus purpureus*), that suggests helping is a strategy for personal gain[10].

We have studied the social behaviour of green woodhoopoes near Naivasha, Kenya, from July 1975 to the present. During the first period of field work (July 1975–May 1976), we individually marked almost all members of 24 flocks, some 148 birds. Subsequently, we have marked an additional 109 woodhoopoes, most of which were juveniles produced in these flocks. We have also recorded and marked immigrants into, and emigrants from, the original groups. Agonistic behaviour is common enough to permit us to assign dominance and subordinate status to most flock members. Thus, kinship ties and social statuses of many flock members are now known.

Social units or flocks of green woodhoopoes consist of 2–16 birds and contain a single breeding pair. Other flock members, usually relatives of one or both breeders, serve as nest helpers. When a flock is decimated, or when a new flock forms, 1–4 females merge with 1 or 2 males; sometimes these social units consist of individuals unrelated to either potential breeder. Unrelated birds of the same sex were usually females[11].

Woodhoopoes of all ages, sex and social classes disappear at a rate of about 40% per year (January 1976–January 1978); we equate most disappearances with mortality[12]. Because of this high mortality, we have obtained information in only three instances concerning the roles of unrelated birds in subsequent breeding activities.

First, in early June 1977 the L-h flock consisted of a single adult male, GL, banded in this territory in late 1975, and four females not present the previous January. Two females, GR and WR, were banded together as immatures in an adjacent territory in August 1975, and were almost certainly siblings. Two younger females, OL and RL, from outside the study area and thus not closely related to GR and WR, were also present. Male GL and female GR bred in early June, with the other three females behaving as nest helpers. RL and OL, unrelated to the nestling, provided more food than did the sibling (WR) of the female breeder (Table 1). Thus, differences in quantity of food delivered to this nest were apparently unrelated to previous foraging experience[13].

Food deliveries by RL and OL increased conspicuously as the nestling matured (Fig. 1). (The increased activity of these helpers was probably not due to increased needs of the single nestling as it grew. During the same period an unaided pair successfully reared two healthy young.) These two birds apparently sought to interact directly with the nestling rather than to deliver food to the female parent, GR. By 13 July, GR remained outside the nest cavity for extended periods, providing the opportunity for helpers RL and OL to enter the nest and feed the nestling directly; from then on their contributions increased proportionately more than did those of the male parent. By 24 July, the nestling perched at the cavity entrance and these helpers groomed and vocalised to the young bird, in addition to feeding it.

Second, in June 1977, the H5 flock consisted of an adult male, OL, his younger male sibling, WR, the adult breeding female, YL, banded in this territory in 1975, a juvenile female offspring, GL, of YL and her previous mate, and a new subadult immigrant female, WL, unrelated to the others. YL soon disappeared and WR returned to his previous territory. Male OL and female WL began courtship feeding and copulation. WL now also occasionally fed GL, then almost a year old and long self-sufficient, and initiated vocal rallies with her. Vocal rallies are an important intra-group behaviour promoting cohesion. In short, WL seemed to develop a closer personal bond with GL. When WL nested in early July, GL became an active nest helper (Table 1), although she was unrelated to either breeder. Female WL, a newcomer to the H5 territory and unrelated to the original breeding pair, thus inherited ownership of a territory, breeding status and a nest helper, GL, within a year or less of her arrival.

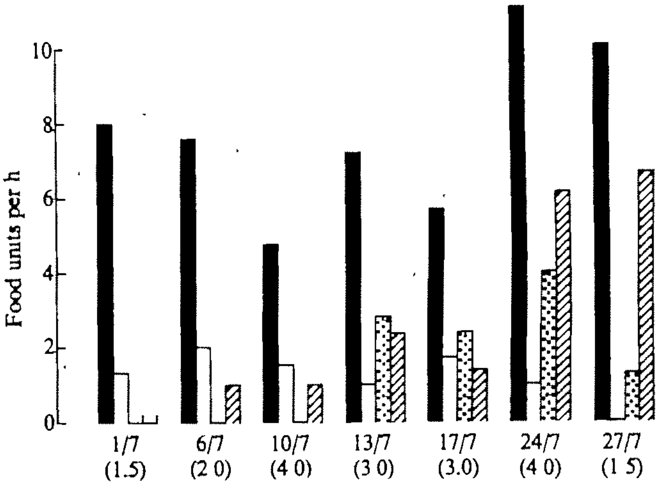

Fig. 1 Food contributions of _ flock members after the single nestling had hatched. Food units are based on size categories; large, medium and small, multiplied by feeding visits. Numbers on the horizontal axis indicate date and in parentheses, the number of hours observation on each date. Flock members are: ■, GL, male parent, □, WR, female sibling of female parent; ⛆, RL, and ▨, OL, females unrelated to either parent OL was not more than 1 yr old. On 13 July the female parent first remained outside the nest for extended periods. From this date on, contributions of RL and OL, in particular, increased proportionately more than did those of the male parent.

Third, in early September 1975, the AD flock consisted of an incubating female and two males. A single young hatched on 17 September. Two females (GR and YR) from an adjacent flock occasionally foraged with the males in the latter's territory as the female breeder incubated, but usually they remained in their own flock, where they helped feed recently fledged juveniles. These females did not visit the AD nest until after the female parent had disappeared, between 7 and 13 October. By the latter date both had joined the AD males, with GR assuming the role of foster mother.

The apparently conflicting interests of the four adults at this nest led to a great variation in feeding patterns. Female GR behaved in typical maternal fashion, often remaining in or near the nest as other flock members foraged elsewhere. When a bird approached the nest with food, GR quickly entered the nest to intercept the food item, presumably passing it on to the nestling.

Table 1 Activities of helpers at two green woodhoopoe nests in 1977

Flock: helpers	Stage of nesting cycle						
	Incubation			Nestling			
	Food units	Feding visits	Non-feeding visits	Food units	Feeding visits	Non-feeding visits	Direct interaction with nestlings*
L-h: (17)				(19)			
♂ GL†	96	45	0	144	71	3	Ca. 12‖¶
♀ WR	7	4	17	24	13	15	5¶
♀ RL	10	6	3	33	18	4	9¶
♀ OL	2	2	5	52	30	1	9¶
H5: (13)				(16)			
♂ OL†	102	54	2	159	89	1	1
♀ GL	32	16	7	114‡	64	6	8
♂ WR	0	0	0	33§	15	0	2

Food units are based on size categories of food brought to the nest: large (3), medium (2), small (1) × feeding visits. Numbers in parentheses indicate hours of observation.

* Includes entering the nest, vocalising directly into the nest, or grooming the nestling at the cavity entrance.

† Male breeders provided significantly more food both to the incubating female and to the nestling(s) than did the helpers (Mann–Whitney U).

‡ GL brought significantly more food to the nest then did WR (Mann–Whitney $U = 21$); GL is unrelated to the nestlings, whereas WR is an uncle.

§ Male WR returned to this territory at about the time the eggs hatched and subsequently fed the young.

‖ Male began to feed young directly when it came to nest entrance. Would not pass food to females other than GR, although several females attempted to take it.

¶ After 10 July both feeding and other interactions increased for the L-h helpers, when the female parent remained outside the nest for extended periods (see Fig. 1).

Female YR almost always gave food to GR, apparently to avoid aggression by the latter. Helper male WL strongly preferred to feed the nestling directly, but GR frequently thwarted him. For example, during a 4-h watch on 16 October, WL attempted 10 times to go directly to the nestling, but was intercepted each time by GR. The male breeder, GL, also frequently attempted to feed the nestling directly, but was equally likely to pass the food to his new mate, GR. GR seemed to behave in a manner designed to condition the males to accept her as the new breeder and to maximise her bonds with the unrelated nestling. The nestling fledged on 22 October and was cared for by all four adults until its disappearance between 13 and 18 November.

Our observations of 13 other flocks, where helpers were either related to the nestlings or where relationships were unknown, also support the suggestion that helpers vie for the opportunity to feed young. We have recorded 69 instances in which one helper has either stolen or begged food from another and then delivered it to the nestlings, and 38 cases where a helper actively avoided the soliciting female parent, to feed the young directly. These apparently disorganised behaviours at the nest make sense if helpers seek to establish personal ties with nestlings, as we suggest.

The data presented here suggest that nestlings, related or not, are valuable resources and that potentially it is to a woodhoopoe's advantage to feed and interact with them (helpers preen and vocalise vigorously to older nestlings), because the helper's subsequent attainment of breeding status and breeding success often depends on the presence of subordinate flock mates (our unpublished work); that is, nestlings are a potential resource for helpers.

In 1978 the contributions of female helpers GL and OL of the H5 and L-h flocks, respectively, were greater than in 1977, even though food was probably less plentiful. This second year of data strengthens the conclusion that such behaviour is adaptive, rather than aberrant.

The cases described here do not support an interpretation of helping behaviour relying on kin-selected altruism. The L-h and H5 flocks each contained a helper closely related to one of the breeders, as well as one or two helpers not related to either. At both nests, young received more food and other attention from unrelated helpers than from relatives. Thus, although most woodhoopoe flocks consist of relatives, these cases suggest that kinship ties (beyond parent–young) and helping behaviour in green woodhoopoes may not be causally related; instead, individual woodhoopoes can apparently gain by helping any young, at least in part because those young might later enhance the helper's future reproductive success.

We thank W. and R. Hillyar, R. and B. Terry, and G. Backhurst for their logistical support, F. Bisleti for allowing us to work on his farm, R. E. Leakey, National Museums of Kenya, E. K. Ruchiami and the Government of Kenya for making this research possible, and R. Thornhill and B. Woodward for comments. Field work was supported by grants from The National Geographic Society, the NSF, the American Museum of Natural History, and the US National Fish and Wildlife Laboratory.

Effect of agrocin 84 on attachment of *Agrobacterium tumefaciens* to cultured tobacco cells

CROWN GALL DISEASE of dicotyledenous plants has aroused considerable interest, partly because of its economic consequences, and partly because it is the only known example of a bacterially induced cancer. The causative organisms are various strains of *Agrobacterium tumefaciens* harbouring large plasmids[1–3]. Parts of these plasmids are transmitted to plant host cells, where they are maintained and transcribed[4,5]. In horticultural conditions, biological control of the disease can be achieved by inoculating susceptible plants with a non-pathogen, *A. tumefaciens* K84 (refs 6, 7) and is due to the production of an intraspecific antibiotic, agrocin 84, by this strain[8]. Although the structure of agrocin 84 has been partially elucidated[9], the mechanism by which it prevents induction of crown gall is poorly understood. We report here the transformation of cultured tobacco cells to crown gall tumour cells and present evidence, using this *in vitro* transformation system, that agrocin 84 blocks the initial step of tumour induction, that is, the attachment of pathogen to host.

Table 1 Effect of agrocin 84 on *in vitro* transformation of habituated tobacco cells by *A. tumefaciens*

Strain	Nopaline content of extracts: Callus tissue (% dry wt)	Nopaline content of extracts: Cell medium (μg ml^{-1})	Tumour development on tobacco plants
C58	0.35	<0.04	+
C58 (agrocin-treated)	<0.01	<0.04	−
C58 (NT-1)	<0.01	<0.04	−
C58(NT-1) (agrocin-treated)	<0.01	<0.04	−

A. tumefaciens C58 and C58 (NT-1) were incubated for 12 h in peptone broth (0.4% Bacto peptone, 0.05% $MgSO_4$, 2% sucrose) and the logarithmically growing cells were collected by centrifugation at 5,000*g* for 15 min at 25 °C. After resuspension in MM growth medium[23] both strains were incubated in the presence or absence of purified agrocin 84 (unpublished data) for 2 h (12 unit ml^{-1}, where 1 unit ml^{-1} is the quantity required to reduce the first order growth rate constant by 50% under defined growth conditions). Aliquots of the four bacterial suspensions were inoculated onto wounded tobacco plants, embedded for electron microscopy and introduced into cultures of habituated tobacco cells maintained in Filner growth medium[24] and incubated at 25 °C in an orbital shaker. These tobacco cultures were incubated for 4 weeks, rifampicin (15 μg ml^{-1}) being added 48 h after infection. Plant cells were separated from growth medium and both were extracted for amino acids essentially as described by Bomhoff[25]. Guanido compounds were detected and estimated by modified versions of the Sakaguchi method[26,27]. A component of the aqueous extract from callus tissue infected with *A. tumefaciens* C58 was identified as nopaline by electrophoresis at *p*H 3.5 and paper chromatography[28] using authentic samples of arginine, octopine and nopaline as references.

A. tumefaciens C58 is a member of the large group of pathogens harbouring the nopaline-type tumorigenic (Ti) plasmids. In addition to coding for enzymes catalysing nopaline synthesis in transformed plant cells and nopaline hydrolysis in the bacteria, these plasmids code for components which render the bacteria sensitive to agrocin 84[2,8,10–13]. When strain C58 is exposed to agrocin 84, a few bacteria develop resistance to the antibiotic. They are avirulent[8] and resemble the 'heat-cured' derivative of strain C58 (named C58(NT-1)), in that they do not carry a Ti plasmid[2].

Many authors have suggested that the first step in the tumour induction process involves a specific interaction of a surface component of the bacterial envelope with wound-exposed

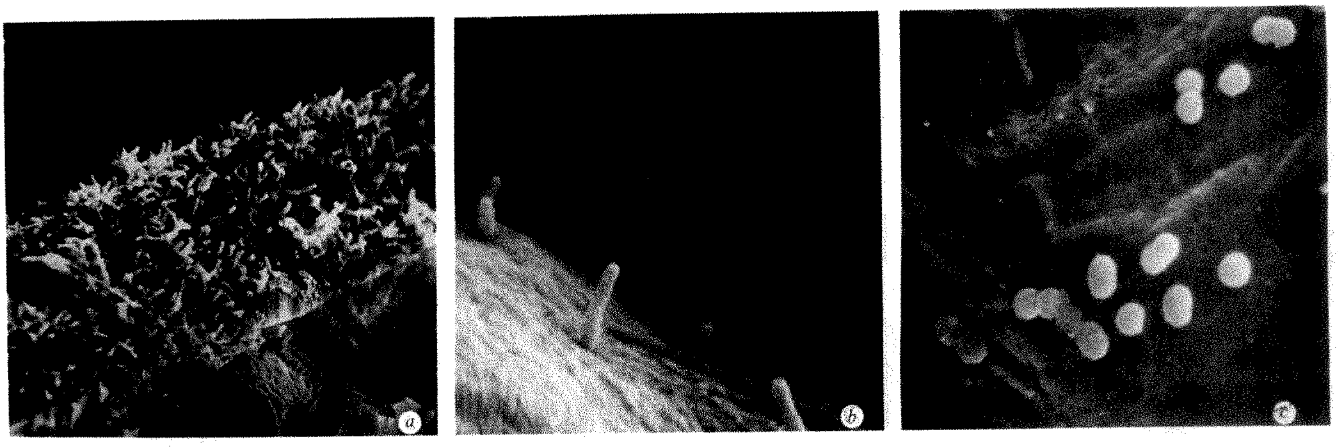

Fig. 1 Scanning electron micrographs of *A. tumefaciens* C58 attached to the surface of habituated tobacco callus cells, 4 h after infection. Magnification of *a*, *b* and *c*, ×1,740, ×34,000 and ×35,800 respectively. In *c* the pathogenic bacteria were preincubated with agrocin 84 for 2 h before inoculation into the tobacco cultures.

portions of the host cell wall[14–16]. Moreover, the correlation between pathogenicity and agrocin 84 sensitivity in *A. tumefaciens* C58 and other nopaline-utilising strains has led to the suggestion that surface receptors which facilitate the adherence of these bacteria to the host cell may also bind agrocin 84 (refs 13, 17). The early events of tumour induction are difficult to study using wounded plant tissue. Thus, by using *A. tumefaciens* C58 and its heat-cured, plasmid-free derivative, strain C58 (NT-1), to infect suspension cultures of habituated tobacco cells, we have developed an *in vitro* transformation system, amenable to a detailed investigation of the initial stages of tumorigenesis and of the role of agrocin 84 in preventing tumorigenesis.

The results of preliminary transformation experiments reported in Table 1 clearly indicate that the *in vivo* and *in vitro* transformation mechanisms are similar. The cultures of strain C58 which induced tumour formation on wounded tobacco plants also induced nopaline synthesis in habituated tobacco cells and both processes were blocked by the action of agrocin 84. Cultures of the heat-cured derivative, strain C58(NT-1), were not able to induce either *in vivo* or *in vitro* transformation. The concentration of nopaline found in C58 transformed tobacco callus cells was similar to that found in excised tumour tissue (J. Firmin, personal communication) and within the limits of detection (0.04 μg ml^{-1}), nopaline was not found in the incubation medium. This finding is perhaps significant in relation to the mechanism of transfer of tumorigenic DNA to non-pathogenic recipients: although octopine is known to increase the frequency of plasmid transfer in octopine-utilising strains of *A. tumefaciens*, nopaline does not enhance the *in vivo* frequency of plasmid transfer in a number of nopaline-utilising strains, including strain C58 (ref. 18).

The idea that *A. tumefaciens* attaches to specific sites in wounded plant tissue originated from the observation that tumour formation could be inhibited by the inclusion of avirulent strains of *A. tumefaciens* in inoculums of virulent strains[19]. If this is the case, then pathogenic and non-pathogenic strains would possess similar affinities for these sites. On the other hand, if an agrocin 84 receptor participates in the attachment of pathogen to host, then a marked difference in the binding properties of pathogenic and non-pathogenic strains would be expected. The *in vitro* transformation system permitted an investigation of these possibilities.

The infection experiments presented in Table 2 were carried out in conditions similar to those used for transformation, but in order to quantify the percentage of free to bound bacteria after a short infection period (4 h) strains C58 and C58(NT-1) were radiolabelled with ^{32}P before agrocin 84 treatment and the subsequent addition of the bacteria to suspension cultures of the plant host. The results obtained do not agree with the hypothesis that pathogenic and non-pathogenic strains have equal affinity for the host, but suggest that the surface properties of pathogenic and non-pathogenic strains of *A. tumefaciens* are different. Whereas over 90% of the pathogenic C58 strain remained associated with the tobacco cells after fractionation, only 15% of the non-pathogenic derivative C58(NT-1) was located there. Furthermore, pretreatment with agrocin 84 consistently reduced the affinity of strain C58 for its host by a factor of two to three, but did not significantly alter the binding capacity of strain C58 (NT-1). The observations made when the infected tobacco cells were examined under the scanning electron microscope corroborated our interpretation of the results of the binding experiments reported above and further, dramatically demonstrated that the formation of a specific infection complex is essential for tumorigenesis. This cytological study revealed that the rod-shaped, non-pathogenic bacteria of strain C58(NT-1) lay recumbent on the surfaces of the tobacco cells, randomly and sparsely distributed. Pretreatment with agrocin 84 had no apparent effect on the morphology or distribution of

Table 2 Comparison of the affinities of strains C58 and C58(NT-1) for habituated tobacco cells after preincubation in the presence or absence of agrocin 84

Strain	Applied bacteria associated with tobacco cells (%)	Average no. bacteria per tobacco cell $(\times 10^{-4})$
C58	93	14.5
C58 (agrocin-treated)	43.8	6.08
C58(NT-1)	15.5	2.96
C58 (NT-1) (agrocin-treated)	12.6	2.90

A. tumefaciens strain C58 and C58 (NT-1) were incubated in peptone broth for 12 h in the presence of $^{32}PO_4$ (5 μCi ml^{-1}). The cells were collected and washed 4 times in iso-osmotic phosphate buffer, *p*H 7.4 (0.155M NaH_2PO_4 adjusted to *p*H 7.4 with 0.103 M Na_2HPO_4). Each strain was then incubated in the presence and absence of agrocin 84 and inoculated into suspension cultures of habituated tobacco cells (see legend to Table 1). After 4 h aliquots of the infected tobacco cultures were layered over Ficoll (15% w/v in phosphate buffer) and centrifuged at 1,800*g* for 1 h. In such conditions 'free' bacteria are pelleted and the tobacco cells remain packed at the Ficoll interface. Approximately the same values were obtained in separate experiments in which separation of plant and bacterial cells was achieved by filtration through siliconised glass fibre filter paper disks. Controls utilised labelled bacteria incubated in plant growth medium in the absence of tobacco cells. Tobacco cells were stained with Trypan blue and counted using a haemocytometer. The specific activities of the bacteria were monitored from turbidity measurements and radioactivity determinations after Millipore filtration.

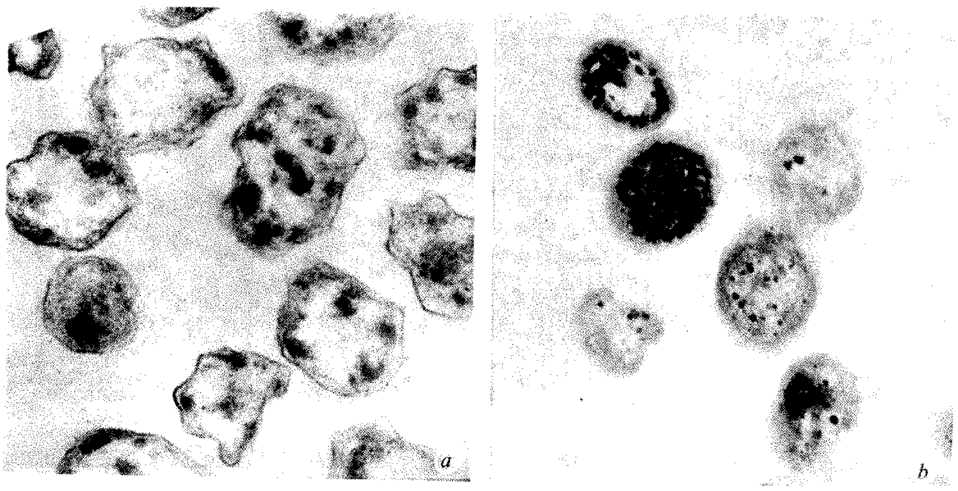

Fig. 2 Electron micrographs of transverse sections through *A. tumefaciens* C58 bacteria. *a*, Normal pathogenic C58 cells, ×2,780; *b*, C58 cells after a 2 h exposure to agrocin 84, ×2,780. The bacteria were prefixed in glutaraldehyde (2% v/v), post-fixed in osmium tetroxide (1% w/v) and embedded in Epon-araldite. Sections were stained with uranyl acetate followed by lead citrate.

these bacteria. In striking contrast however, the pathogenic C58 bacteria exhibited a marked tendency to cluster together and isolated cells were rarely observed. The bacteria did not apparently cluster around lesions in the host cell wall, but in some cases the entire surface appeared to be enveloped by the bacteria and in others localised areas were densely populated (Fig. 1*a*). Furthermore, the rod-shaped cells were orientated such that one end was embedded in the plant cell surface (Fig. 1*b*) and often a halo of diffuse material was observed around these bacteria. We do not consider that the observed polar attachment of bacteria to host is an artefact of the dehydration and fixation procedures as a previous cytological study of plants infected *in vivo* with *A. tumefaciens* showed the same phenomenon[14] and this is the mode of attachment of members of the closely related genus *Rhizobium*[20] to the tips of root hairs of their plant hosts[21].

The effect of agrocin 84 on strain C58 was immediately obvious; clustering was still apparent, but the majority of the bacteria were spherical and paired (Fig. 1*c*). As agrocin 84 is bacteriostatic (data not shown), the observation that the agrocin 84 treated cells were often located in pairs on the surfaces of the host suggested that bacteria which had entered the division cycle were unable to complete the process after the additon of agrocin 84. The further observation that these cells had rounded up suggested that agrocin 84 may act by disrupting the integrity of the cell wall.

To compare the anatomical features of normal and agrocin-treated bacteria, thin sections of these cells were examined under the transmission electron microscope. The electron micrographs shown in Fig. 2 are representative of our observations: untreated pathogenic cells of strain C58 were indistinguishable from cells of strain C58(NT-1) preincubated in the presence or absence of agrocin 84 and in all cases the cell envelopes were clearly defined. In contrast, the envelopes of agrocin-treated C58 cells were, when present, ill-defined and fragmented. Additionally, only these agrocin-treated cells contained large, electron dense granules and thus we suggest that agrocin 84 interferes with the synthesis of the cell wall rather than acting on preformed structures and that the granules may represent a build up of cell wall precursors.

The data presented here support the hypothesis that the cell surfaces of strain C58 and C58(NT-1) are different and that this difference is due to the presence of the tumorigenic plasmid (data not shown and ref. 2). The Ti plasmid of strain C58 seems to code for enzymes involved in the synthesis of surface components, believed to be capsular lipopolysaccharides[22], which mediate the specific attachment of bacterium to host. It is possible that these same components are also directly responsible for sensitivity to agrocin 84, but we consider this unlikely. Sensitivity to agrocin 84 is strictly dependent on the nutritional status of strain C58 and growth media which promote the synthesis of capsular lipopolysaccharide completely inhibit agrocin 84 sensitivity (data not shown). Furthermore, amongst the nopaline-utilising strains of *A. tumefaciens*, some pathogens are insensitive to agrocin 84 and conversely, some non-pathogens retain sensitivity (data not shown and ref. 13). Thus the correlation between pathogenicity and agrocin 84 sensitivity may be fortuitous rather than direct. We propose that agrocin 84 prevents tumorigenesis by causing the fragmentation or loss of the cell envelope and thereby impairing the ability of the bacterium to transfer tumorigenic DNA to its host. As agrocin 84 sensitivity is plasmid-coded in strain C58, the subsequent loss of this plasmid from cells incubated in the presence of this antibiotic is a requirement for survival.

We thank Dr J. Abbott for providing habituated tobacco callus tissue and Dr J. L. Firmin for synthetic nopaline. This project was supported by the SRC (studentship to V.S.) and the MRC (grant no. G 976/626/C).

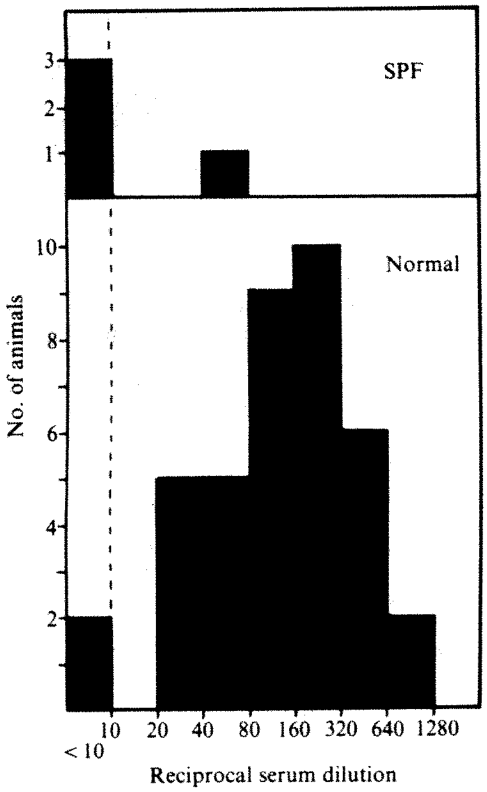
Neutralisation of respiratory syncytial virus by cat serum

RESPIRATORY SYNCYTIAL (RS) virus has been identified as a major cause of lower respiratory infection in infants, and the epidemiology of RS virus infection is characterised uniquely by annual winter outbreaks in the infant population and by antigenic stability of the virus[1]. The initial isolation of RS virus was from a captive chimpanzee[2] and more recently an antigenically similar virus has been associated with respiratory disease in cattle[3–5]. The bovine and human RS viruses, although antigenically similar, can be differentiated by their different host range *in vitro*[6]. The bovine RS virus had a wider host range, multiplying in bovine, hamster, swine and primate cells, whereas the human RS virus multiplied only in bovine and primate cells. We have observed recently, however, that human RS virus (but not bovine RS virus) can multiply efficiently in secondary cultures of feline embryo cells. The cytopathology induced by RS virus infection of feline embryo cells was similar to that described previously for African green monkey (BS-C-1) cells[7]: the surfaces of infected cells were seen to be covered by long slender filaments when viewed by scanning electron microscopy or by immunofluorescent staining (C.R.P. and J. E. Parry, unpublished data). The susceptibility of feline embryo cells to RS virus, and an observation that the sera of some laboratory cats in the USA inhibited RS virus (R.M. Chanock, personal communication), suggested that cats might be susceptible to RS virus infection. We therefore examined a random sample of cat sera, and we show that antibody to RS virus is widespread in domestic cats in Britain.

Fig. 1 Histogram of RS virus-neutralising activity in normal and SPF cats. Approximately 10^4 plaque-forming units of the RSN-2 strain of RS virus were mixed with twofold serial dilutions of each serum, and incubated at 4 °C for 18 h. The infectivity remaining in each tube was assayed by titration on BS-C-1 monolayers. The percentage reduction of infectivity was determined by plaque counting after a 7-d incubation at 31 °C under 0.9% (w/v) agar overlay and plotted against serum dilution. The dilution producing a 50% reduction of infectivity was determined graphically for each serum.



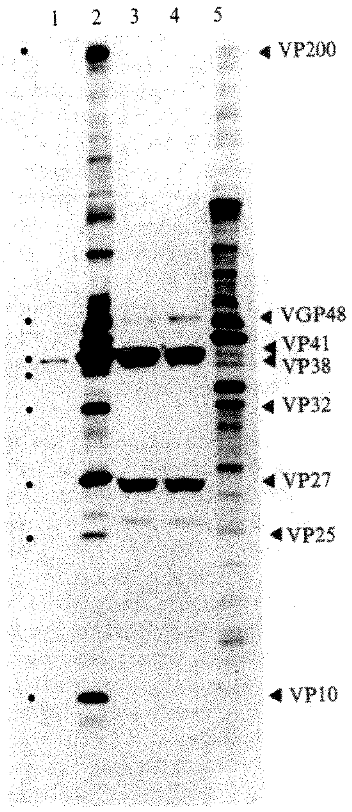


Fig. 2 Autoradiogram showing virus polypeptides precipitated by feline and bovine sera. Serum was incubated with ^{35}S-labelled RS virus-infected cells or a polyethyleneglycol (PEG) extract prepared from them for 1 h at 37 °C. Antibody–antigen complexes were precipitated with formalin-fixed heat-killed *S. aureus*[10]. Washed *S. aureus* precipitates were incubated at low *p*H to break antigen–antibody bonds. Viral antigens released into the supernatant were run on SDS-polyacrylamide gels (5.5–12% acrylamide gradients). Track 1, immunoprecipitate, cat serum + PEG extract of RS virus-infected cells, showing VP41. This band was absent when uninfected cells were used. Track 2, control. Radiolabelled RS virus-infected cells. Track 3, immunoprecipitate, bovine serum + PEG extract of RS virus-infected cells. Track 4, immunoprecipitate, bovine serum + RS virus-infected cell pellet. Track 5, control, radiolabelled uninfected cells.

Thirty-nine cat sera were obtained, representing a random selection of animals ranging from 2 months to 10 years old, 19 of which had been collected in 1975–6 and 20 in 1977–8. Four sera from specific pathogen-free (SPF) animals were also examined. The neutralising activity of these 43 sera was assayed as described in the legend to Fig. 1, and the 50% neutralisation end-points were determined graphically by plotting percentage recovery against serum dilution. The RSN-2 strain of RS virus[7] was used as the test virus. The results are presented in Fig. 1. Thirty-seven of the thirty-nine sera from normal cats had neutralising activity, with a geometric mean titre of 1/147, and only two were negative (<1/10). Three of the four sera from SPF cats, on the other hand, were negative (<1/10) and the one positive serum had a titre of 1/50 (approximately threefold less than the mean titre of the normal group). These results show clearly that the majority of the sera of domestic cats in this sample were able to neutralise the infectivity of RS virus. There was no obvious correlation between the level of neutralising activity and age of the animals, and the titres of the sera collected in 1975–6 and 1977–8 were distributed similarly. The greater frequency of negative sera from SPF animals (0.75 compared with 0.05 for normal animals) suggests that the neutralising activity represented an immune response.

This conclusion was supported by the result of an experiment in which extracts of ^{35}S-methionine-labelled infected and uninfected BS-C-1 cells were mixed with either a high titre convalescent bovine anti-RS virus serum, or one of the cat sera with

0028–0836/78/0276—0501$01.00

high neutralising activity (1/768). The method of radiolabelling was as described previously[8,9]. Antigen–antibody complexes were precipitated with fixed *Staphylococcus aureus* as described in the legend to Fig. 2. The bovine anti-RS virus serum precipitated VGP48, VP41, VP38, VP27 and VP25, but not VP200, VP32 or VP10 (tracks 3 and 4 in Fig. 2). Significantly, no polypeptides corresponding to the high molecular weight glycopolypeptides described as RS virus-specific by Levine[11] were observed, confirming our previous interpretation[8,9] that these polypeptides were host-derived. Figure 2, track 1, shows that the cat serum possessed antibody able to combine with a viral protein which electrophoresed with the mobility of VP41, the nucleoprotein of RS virus[8,9]. No corresponding band was observed when the serum was reacted with uninfected cells (data not shown).

These observations suggest that most, if not all, domestic cats in this locality have experienced RS virus infection. The presence of neutralising activity in the sera of cats of all ages (and in one of the four SPF animals) suggests that cats may be highly susceptible to RS virus infection, and that they are exposed to infection early in life. It remains to be determined whether illness is associated with infection, and whether the virus inducing the immune response is transmitted horizontally among cats. It is possible that a feline RS virus exists, but as yet none has been isolated. The relevance of these observations to the human disease pattern is a question which merits further investigation.

We have not been able to detect RS virus antibody, however, by indirect immunofluorescent staining of acetone-fixed RS virus-infected cells using pooled and absorbed cat sera and an FITC-conjugated rabbit anti-cat globulin (Nordic). It would appear that the immunoprecipitation of radiolabelled viral protein is the more sensitive method for detection of RS virus antibody in cat serum.

We thank Pat Malloy and Karen Brunton for technical assistance, Dr P. V. Shirodaria for assistance with the immunofluorescence experiment, Dr J. Stott for bovine anti-RS virus serum, and Dr O. Jarrett for co-operation and for cat sera.

HLA-DR specific human suppressor lymphocytes generated by repeated *in vitro* sensitisation against allogeneic cells

THE HLA complex is composed of a set of genes closely linked on chromosome 6, which may have important functions in the regulation of the immune response. The HLA-A, -B and -C loci control serologically defined antigens present on most cells. The HLA-D region controls two groups of determinants: (1) HLR-DR (DRw1 to DRw8) antigens, restricted to B lymphocytes, detected by serology and equivalent to the I region-associated antigens (Ia) of the mouse; (2) HLA-D stimulating products (Dw1 to Dw11) defined by mixed lymphocyte reactions (MLR). Sensitisation of human lymphocytes with irradiated allogeneic stimulatory cells *in vitro* produces primed lymphocytes[1–5]. These *in vitro* primed lymphocytes develop an accelerated secondary proliferative response when restimulated by the specific priming cell or by any cell possessing HLA-D region products identical to the priming cells. Familial and population studies[6,7] show this secondary proliferation (MLR II or PLT) to be more correlated to HLA-DR antigens serologically detected than to D specificites defined by HLA-D typing (MLR I). It has also been suggested that, within informative families bearing haplotypes with unusual associated D-DR products, DR antigens and HLA-D stimulating products could be distinct determinants[7]. However, absolute proof—a recombination between these two products—is still lacking. The accelerated proliferative capacity of primed lymphocytes represents a function which depends on the allogeneic contact; we have investigated the possible induction of suppresor cells by repeated *in vitro* sensitisation. We show that lymphocytes sensitised twice '*in vitro*' behave as active suppressors of the allogeneic response and are specific for the HLA-DR antigens presented by the stimulator lymphocytes.

Table 1 Decrease in the specific proliferative response of the twice-primed PLT cells (PLT II)

6,049	7,628	9	2/7	—
12,111	14,763	10	7/3	—
8,728	10,194	11	5/–	—

PLT I (anti DRw1 was produced within a normal family by sensitising *in vitro* 10×10^6 lymphocytes (isolated by Ficoll–Isopaque gradient) from the father DER. F (DRw2/–) with 10×10^6 2,500 rad γ-irradiated cells from his child DER. C (DRw2/DRw1) in 20 ml RPMI 1640 with 20% normal pooled human plasma and antibiotics (100 mg ml^{-1} streptomycin, 100 IU ml^{-1} penicillin), in plastic culture vials (Falcon 3013). They were incubated at 37°C in a 5% CO_2 air atmosphere for 10 d. PLT II was produced by sensitising a second time *in vitro* 10×10^6 PLT I cells with 10×10^6 irradiated cells from the same stimulator over 7 d. PLT testing was carried out in V-bottom plastic culture microtrays: 5×10^4 responders in 0.05 ml and 5.10^4 stimulators in 0.1 ml were added in each well. 48 h later cultures were pulse-labelled for 18 h using ^{3}H-thymidine (2 μCi per well) (specific activity, 1 Ci $mmol^{-1}$) and counted in a liquid scintillator. HLA-DR antigens were determined serologically and by PLT testing. Per cent suppression was calculated using the formula:

$$\%\ \text{Suppression} = \frac{1 - \text{test c.p.m. median value}}{\text{control c.p.m. median value}} \times 100$$

* Median values of three cultures.
† NC, negative control; SC, specific control.

The first indication that a suppressive activity can be detected in secondary cultures comes from the observation that twice-sensitised PLT cells (PLT II) give a lower accelerated proliferative response when restimulated by specific cells than classical PLT sensitised only once (PLT I). The kinetic study of this secondary proliferation has clearly shown that the proliferation was decreased and not delayed (data not shown). The proliferative response of PLT DER AC (PLT I) (an intrafamilial PLT generated against a DRw1-bearing haplotype) was compared with the response of the same PLT sensitised twice (PLT II) by the same priming cell (Table 1). The proliferative response of PLT I (anti DRw1) was significantly higher than the response of PLT II against DRw1-positive cells. As expected, both PLTs give the same low response against DRw1-negative cells. These results suggest that the lower specific response obtained with the twice-primed PLT (PLT II) is due to (1) depletion of the specific

0028–0836/78/0276—0502$01.00

responding cells, or (2) to the generation of active suppressor cells after multiple *in vitro* restimulations. The latter hypothesis has been tested in a three-cell assay.

The three-cell assay is a proliferative assay; the three co-cultured cells were unprimed responding cells, irradiated stimulating cells and possible suppressor cells (responder cells primed twice and γ irradiated). The proliferative responses in the presence or absence of the suppressor cells were evaluated and compared on day 7 of culture. The results of experiments of this kind are shown in Tables 2–5. Addition of twice-primed irradiated cells (PLT II) in a three-cell assay induced an active suppression in some combinations. The specificity of this suppression was analysed using well typed unrelated and informative familial cells. It was first observed that a PLT II anti-DRw7 in family DEG (Table 2) was only suppressive when added in the combinations where the stimulating cells possess 'a' haplotype which codes for the DRw7 antigen. In the same experiment the response against an unrelated stimulating cell, GIL, DRw7/DRw7, was also suppressed. The specificity of the suppression in this and other families (data not shown) seemed to segregate with an HLA haplotype.

A more precise analysis of the specificity of the suppression was carried out by using an HLA-B/D recombinant family (BAR) in a three-cell assay (Table 3). PLT II anti-DRw7 cells were added in combinations using all the members of the family BAR as stimulators. A specific suppression for the DRw7-bearing 'b' haplotype was observed within this family. The combination with the recombinant child C1 who has only inherited the HLA-D part of the b haplotype was also suppressed. The specificity of the suppression seems to be HLA-D region specific.

The apparent specificity of the suppression for the HLA-D-region products could involve either DR antigens or D products—if these are distinct determinants. However, in familial cases where an unusual association between HLA-D and DR specificities occurs on one HLA haplotype, the respective role of the two 'different' products could be studied separately. An example is shown in Table 4: in family LIS an unusual haplotype was recognised previously, in which DRw1 is associated with Dw4 (instead of the usually observed DRw1–Dw1 association). A PLT II twice primed against an haplotype DRw1 Dw1 was added in combinations where different stimulators were used, either DRw1 Dw1 or DRw1 Dw4 bearing cells. A specific suppression for the DRw1 antigen of the stimulator was observed to be independent of the associated Dw specificity.

Experiments with lymphocytes primed against two DR specificities were also carried out. These lymphocytes were discriminative bispecific PLT reagents. Using repeated sensitisations with one or the other specificities, we sought to establish whether they could independently generate suppressors specific for one or the other DR antigen. For instance, DRw2/DRw2 lymphocytes were primed against cells possessing DRw5/DRw7 antigens for 10 days (bispecific PLT I) and co-cultured for 7 more days with either a DRw5/DRw5 or DRw7/DRw7 stimulator (PLTs II). The suppressive activity of these PLTs II was tested in a three-cell assay (Table 5). The bispecific PLTs restimulated by DRw5 antigens greatly suppressed the response against DRw5-positive cells, whereas the suppression of the response against DRw7-positive cells was lower. The opposite was observed when restimulation was carried out with DRw7 antigens. This suggests that there are two distinct classes of suppressors—one specific for DRw5-positive cells and the other for DRw7-positive cells.

Table 2 Suppression follows the HLA haplotype

Culture conditions were as reported in Table 1. PLT II was produced as follows: responder, DEG C7 (DRw3/–), and stimulator irradiated father, DEG. F (DRw3/DRw7) were co-cultured for 10 d (PLT I). These cells were restimulated for 7 d with an irradiated homozygous cell (DRw7/DRw7) and gave PLT II cells. Three-cell assays were carried out with: (1) responder cell unprimed, DEG. C7 (DRw3/–) (5×10^4 cells); (2) irradiated stimulating cells with different DR specificities (5×10^4 cells); (3) third irradiated cells either PLT II or DEG (DRw3/–) (5×10^4 cells). The proliferative response was evaluated on day 7 of culture, and the per cent suppression calculated as in Table 1.

PLT I produced with LER (DRw2/DRw2) as responder, and VDL M (DRw5/DRw7) as irradiated stimulator gave an anti DRw5 + DRw7 (PLT I) after 10 d. These cells sensitised a second time (7 d) against an homozygous irradiated cell (DRw7/DRw7) gave the PLT II cells. Three cell assays were carried out: (1) responder cell unprimed (LER DRw2/DRw2); (2) irradiated stimulating cells from members of family BAR. (in this family child C1 is a known HLA-B/D recombinant; (3) third irradiated cells, either PLT II (responder primed twice) or LER (DRw2/DRw2). The proliferative response was evaluated on day 7 of culture as for Table 2.

* Medium values of three cultures.

PLT I produced with DER. F (DRw2 Dw2/–) as responder and DER. C, (DRw2 Dw2/DRw1 Dw1) as irradiated stimulator, gave after 10 d an anti-DRw1 PLT I; sensitised a second time, with the same irradiated stimulator for 7 d it gave PLT II cells. Three-cell assays were carried out with: (1) responder cell unprimed: DER F (DRw2 Dw2/–); (2) irradiated stimultaing cells from family members and unrelated donor's cells, (3) third irradiated cells, either PTL II (responder primed twice) or DER F, (DRw2 Dw2/–). HLA-D typing was carried out using HLA-D homozygous typing cells (7th Histocompatibility Workshop cells) in a standard micro MLR assay. The results were double normalised (according to the method of Ryder *et al.*[18]. DR determinants were as for Table 1.

* Medium values of three cultures.

Bispecific PLT I was produced with LER DRw2/DRw2 as responder and VDL M (DRw5/DRw7) as irradiated stimulator. PLTs II were produced by sensitising PLT I cells a second time with either cells GIL (DRw7/DRw7) = PLT II A or cells MAI (DRw5/DRw5) = PLT II B for 7 d. The three-cell assay was carried out as follows with: (1) responder cell unprimed· LER (DRw2/DRw2), (2) γ-irradiated stimulating cells with different specificities (DRw5, DRw7, DRw3 ...); (3) third γ-irradiated cell: either PLT II A or B (responder primed twice, see Table 2) or LER (DRw2/DRw2).

These experiments indicate that lymphocytes which have been sensitised twice *in vitro* contain active suppressor cells, capable of suppressing 30–80% of the allogeneic proliferative response of unprimed cells. These *in vitro*-generated suppressor cells are radioresistant and specific for the HLA-DR antigens or closely associated structures presented by the stimulator lymphocytes. The suppressive activity of lymphocytes primed against two HLA-DR antigens seems to be induced by two distinct populations of suppressor cells. These suppressors behave (at least for the specificity of the suppression) in the same way as described for lymphocytes from a multiparous woman[8,9] which were spontaneous suppressors of the response against HLA-D-region products of her husband, and were also radioresistant. However spontaneous suppressors specifically restricted to HLA-A specificities have also been reported[10].

In vitro-generated suppressor cells are probably T lymphocytes, as only T cells are known to proliferate in MLR; however, there is no direct evidence. Cell-mediated lymphocytotoxicity cannot explain the suppression phenomenon for at least two reasons. (1) In our system, cell division was inhibited by irradiation, which prevents reactivation of the cytotoxicity of the twice-primed lymphocyte population[11]. (2) In contrast to the suppression observed here, the specificity of the lymphocytotoxicity has not so far been shown to be directed against HLA-DR antigens[12]. An antigenic competition, even though unlikely, cannot be definitely excluded. We shall investigate a possible HLA restriction phenomenon between the responder and the suppressor lymphocytes as well as a possible suppression mediated by soluble factors.

These HLA-DR-specific *in vitro*-generated human suppressors are probably similar to the spontaneous suppressors described *in vivo* after pregnancy[8,9]. On the other hand, this allogeneic phenomenon seems to be different from other suppressors reported in human, such as those induced by mitogenic stimulation[13–16] and observed in various diseases[17]. The suppression described here can be considered as a balanced phenomenon involving interaction between different lymphocyte populations such as 'helper cells', responsible for the allogeneic proliferative response and 'suppressor cells', antagonists of helper cell activity. This phenomenon might be of great importance during pregnancy and in allograft tolerance.

We thank Mrs A. Soulie, F. Pasquier and Mr P. Barban for technical assistance and Miss E. Wollman, Mr R. Ollo and D. Cohen for help and discussions. This work was supported by a grant from the Institut National de la Santé et de la Recherche Médicale (ATP 59.78,91).

Postnatal cerebellar cells from staggerer mutant mice express embryonic cell surface characteristic

MORE than 100 mutations affecting neurological function have been described in mice[1]. In one of these, staggerer[2,3], the development of normal synaptic relationships between cerebellar granule cells and Purkinje cells is disturbed[4–6]. In a search for abnormalities in the cell surface of staggerer cerebellar cells, we have measured cell agglutination in the presence of the plant lectins concanavalin A (Con A) and wheat germ agglutinin (WGA). We report here that cell surface properties necessary for WGA-induced agglutination are abnormal in the mutant cerebellar cell population whereas those necessary for Con A-induced agglutination are not. These results are consistent with the persistence of a characteristic of the embryonic cerebellar cell surface.

Wild-type and staggerer animals maintained on A C57−+*d se*/*sg* ++ inbred background were obtained from the breeding colony of our department[7]. Homozygous staggerer offspring were identified by their black coat and neurological symptoms[2]. All mice were decapitated on the seventh and tenth days after birth (P7, P10), P7 being the earliest age when staggerer animals could be identified. Wild-type littermates were identified by their dilute coat colour. Cerebella were removed and single cell suspensions were prepared by dissociation with trypsin-DNase followed by gentle trituration[7,8]. Cell yield was $2\text{–}3\times10^6$ per P7 staggerer cerebellum and $1\text{–}2\times10^7$ per P7 wild-type cerebellum.

To allow recovery from brief exposure to trypsin during dissociation, cells were preincubated in Ham's F12 medium supplemented with horse serum (2%, Microbiological Associates) for 6 h at 35.5 °C. The serum was removed by washing twice with phosphate-buffered saline (PBS, 600 r.p.m., 5 min, 4 °C), and the cells were resuspended (1×10^6 cells per ml of PBS) for agglutination assays.

As described previously[10] (summarised in Table 1), early embryonic wild-type cerebellar cells are highly agglutinable with both Con A and WGA. This agglutinability is lost, however, after about embryonic day 16, such that postnatal cerebellar cells require very high concentrations of the lectins for agglutination. In contrast, P7 and P10 staggerer cerebellar cells were highly agglutinable with WGA. Hapten-specific inhibition of staggerer cerebellar cell agglutinating activity (%) was measured in quadruplicate with WGA (100 μg ml^{-1} in PBS) preincubated (15 min, 20 °C) with the inhibitor. In those conditions, WGA-induced agglutination of P7 staggerer cerebellar cells was inhibited completely by *N*-acetyl-D-glucosamine (0.40 mM), *N*-*N*-di-*N*-acetylchitobiose (0.04 mM), chitin hydrolysate (prepared by Rupley's method[11] and approximately 0.02 mM, 1% w/v; hydrolysate demonstrated by paper chromotography to consist primarily of di- and trisaccharides) and ovomucoid (0.02 mg ml^{-1}). Agglutinating activity was not reduced by more than 50% by D-glucosamine (50.0 mM), D-galactose (50.0 mM), *N*-acetyl-D-galactosamine (50.0 mM) or methyl-α-D-mannoside (50.0 mM). These results agree with the reported carbohydrate binding specificity of WGA[12,13].

Table 1 Agglutination of staggerer and wild-type mouse cerebellar cells with Con A and WGA

Genotype	Age	WGA	Con A
Wild-type C57BL/6J	E13	50	200
	P0	450	800
	P3	>500	>1,000
	P7	>500	>1,000
	P10	>500	>1,000
Wildtype +*d se*/+ *d se*	P7	>500	>1,000
	P10	>500	>1,000
Staggerer *sg* + +/*sg* ++	P7	55	>1,000
	P10	48	>1,000

Values for C57BL/6J embryonic animals are taken from ref. 10. Values for postnatal wild-type and staggerer animals are given as lectin concentration (μg ml^{-1}) required for half maximal agglutination (75%). For details of the assay method see refs 9 and 10 Agglutination assays were carried out in quadruplicate. Results given are averaged values from four sets of assays, each set having been carried out with animals from a separate litter. 20 staggerer animals and 10 wild-type animals were studied. The variability among quadruplicate assays of lectin concentration required for half maximal agglutination was less than 15 μg ml^{-1}.

Table 2 Recovery of P7 wild-type and P7 staggerer cerebellar cells from exposure to trypsin

Genotype		Con A (μg ml^{-1})	WGA (μg ml^{-1})
Wild-type	*a*)	150	50
+*d se*/ + *d se*	*b*)	>1,000	>500
	c)	160	65
Staggerer	*a*)	150	50
sg + +/*sg* ++	*b*)	>1,000	50
	c)	150	50

Lectin concentration (μg ml^{-1}) required for half maximal agglutination (75%). Agglutination assays were carried out in quadruplicate by the method of Burger[9] *a*, Agglutination immediately following dissociation of cerebellar tissue into a single cell suspension[7,8]. *b*, Agglutination of dissociated cells replaced in Ham's F12 medium supplemented with horse serum (2%, Microbiological Associates) for 6 h, at 35.5 °C before the assay. *c*, Agglutination of dissociated cells replaced in growth medium as above for 6 h followed by exposure to trypsin (crystalline, Worthington, 10 μg ml^{-1} in PBS) for 10 min at 37 °C. Subsequently ovomucoid (10 μg ml^{-1} in PBS) was added, the trypsin was removed by washing the cells three times in PBS (600 r.p.m., 5 min, 4 °C), and the cells were resuspended for agglutination assays. The variability among quadruplicate assays of lectin concentration required for half maximal agglutination was less than 15 μg ml^{-1}.

As with early postnatal wild-type cerebellar cells, cells derived from staggerer mice were not agglutinable with Con A at P7 or P10 (Table 1). They could be agglutinated only by high lectin concentrations or by brief proteolysis as described below. The latter agglutination was specifically inhibited by methyl-α-D-mannoside (2.0 mM) but not by other haptens, in agreement with reports of Con A binding specificity[12–14].

Interestingly, the cell surface abnormality in staggerer cerebellar cells was restricted to components involved in WGA-induced agglutination. In studies of wild-type cells from several brain regions, WGA-induced agglutination depended on the region of origin and age of the cells as well as the enzymatic treatment to which the cells had been subjected. Whereas cells from the embryonic cerebellum agglutinated with low concentrations of WGA[11], those from neural retina[15], midbrain, medulla and cerebral cortex agglutinated only immediately after trypsinisation[11]. The abnormality of the staggerer cerebellar cells could thus reflect the persistence postnatally of the early embryonic cell surface characteristics which result in high agglutinability by WGA.

This conclusion depends on the recovery by the cells from the effects of the trypsin used to prepare the cell suspension, and on the absence of large changes in the different cell populations caused by selective granule cell degeneration in mutant staggerer cerebellum. Evidence for the recovery of both wild-type and staggerer cerebellar cells from the effects of trypsin is presented in Table 2. Before replacing cells in growth medium for 6 h, P7 and P10 cerebellar cells collected from wild-type and staggerer animals were highly agglutinable with both Con A and WGA (Table 2*a*). This agglutination was hapten-specific, Con A-induced agglutination being inhibited exclusively by methyl-α-D-mannoside[12,16] (2.0 mM) and WGA-induced agglutination by *N*-acetyl-D-glucosamine After incubation in growth medium for 6 h, the Con A- and WGA-induced agglutinability of wild-type cells and the Con A-induced agglutinability of staggerer cells decreased markedly (Table 2*b*). To directly assess the response of recovered cells to trypsin, we subjected them to a second mild proteolysis. The result was a second increase in the Con A- and WGA-induced agglutinability of wild-type cells and in the Con A-induced agglutinability of staggerer cerebeller cells. A second exposure to trypsin did not further increase the WGA-induced agglutination of staggerer cells (Table 2*c*).

These results are consistent with the effects of brief exposure to trypsin on the response of several cell types to Con A and WGA. Trypsin reversed non-agglutinability but did not affect high agglutinability[16-19]. Trypsin also has a transient effect on 3T3 cells, BHK cells and chick embryo fibroblasts, which become refractory to increased lectin-induced agglutinability within 6 h of the removal of the trypsin[20-22].

At P7, the age with which we are chiefly concerned here, the granule cell population of staggerer is 50% smaller than that of wild-type cerebellum. The other major cell populations, Purkinje cells and glial cells, are not different for staggerer[24,25]. The three- to fivefold decrease in total cell yield we obtained for staggerer cerebellum was therefore due primarily to the selective loss of granule cells. To assess whether a smaller proportion of granule cells in the cell suspension influenced our agglutination results, we resuspended wild-type cerebellar cells at 3×10^6 instead of 1×10^6 cells per ml for agglutination assays. Agglutination of this cell suspension by Con A and WGA was identical to that reported in Table 1. It is therefore unlikely that dilution of other cell populations by the larger granule cell population in wild-type cerebellum exclusively explains the difference in WGA-induced agglutination found for staggerer cerebellar cells. This interpretation is strengthened by recent studies showing that lectin-induced agglutination can be used to separate out a subpopulation of undifferentiated cells from a mixed population of cloned embryonal carcinoma cells[26].

Because the agglutination assays were carried out in suspension, it is not possible to identify the cell type in the staggerer cell population which is the site of the abnormality in WGA-induced agglutination. We shall investigate this by electron microscopy of agglutinated cells and by histochemical studies of WGA-binding to frozen tissue sections.

We thank Dr R. L. Sidman for support, Drs T. O. Fox, R. J. Mullen, J. Noebels, E. Trenkner and C. Vito for critically reading the manuscript, Dr M. M. Burger for Con A and WGA, and Dr R. W. Jeanloz for *N*-*N*-di-*N*-acetylchitobiose. This work was supported by NIH a postdoctoral fellowship 5 F32N505271-02 (to M.E.H.), by NIH grant RO1-NS-1123705 (to R. L. Sidman) and by a special fellowship from the Medical Foundation of Boston (A.M.).

Erythroid bursts produced by Friend leukaemia virus *in vitro*

WHEN mouse haematopoietic cells are incubated in plasma clot or methyl cellulose cultures in the presence of erythropoietin (EP), at least two kinds of colonies are observed[1-4]. After 2 days, randomly distributed erythroid colonies (defined as a clone of eight or more benzidine-positive cells) appear[1,2], and after 3–8 d of culture with higher concentrations of EP, larger colonies arise in clusters or 'bursts'[3,4]. The cells of origin have been termed the colony-forming unit-erythroid (CFU-E)[1] and burst-forming unit-erythroid (BFU-E)[3,4], respectively. Erythropoiesis in mice is also increased considerably by the Friend virus complex[5,6], which has been studied mostly *in vivo* although there are systems for the study of erythroid transformation *in vitro* soon after infection[7-10]. Nooter and Bentvelzen[11], using methyl

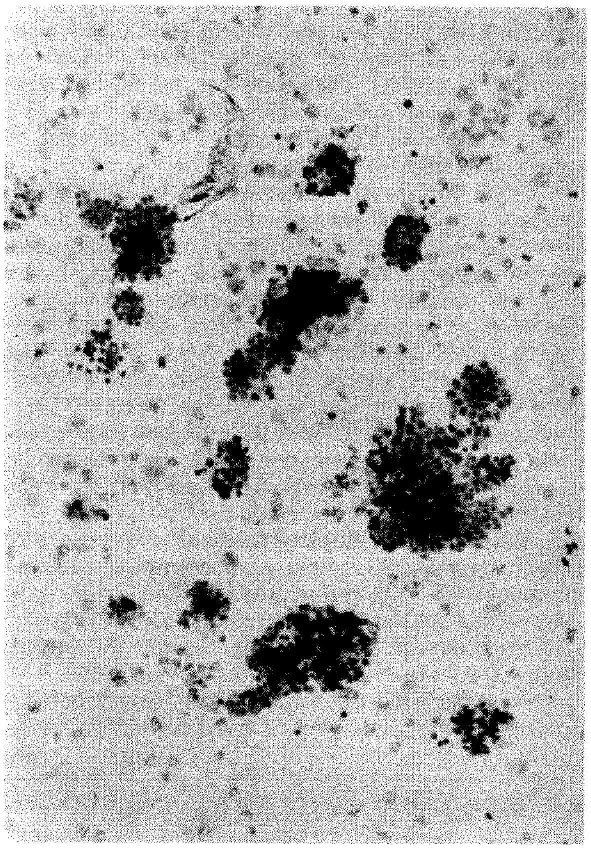

Fig. 1 Erythroid bursts produced by Friend virus infectious plasma. BALB/c mice were given three intraperitoneal injections (0.04 mg per g) of phenylhydrazine hydrochloride 62, 48 and 40 h before killing. When the mice had been killed, marrow cells were flushed from the tibias and femurs with sterile Hanks balanced salt solution (HBSS). The cells were washed twice with HBSS and collected each time by centrifugation. 4×10^6 nucleated cells were resuspended in 0.3 ml of a 1:20 dilution of Friend virus infectious plasma in alpha medium (7,500 spleen focus-forming units[18] and 1.5×10^5 XC plaque forming units[19]). This cell suspension was incubated at 4 °C for 1 h. The virus–cell mixture was then diluted to 2 ml to give the following final concentrations: bovine serum albumin, 1% v/v; penicillin, 100 IU ml^{-1}; streptomycin, 100 μg ml^{-1}; β-mercaptoethanol, 10^{-4}M; fetal calf serum, 30% v/v; beef embryo extract, 0.85% v/v; bovine citrated plasma, 10% v/v. This mixture was pipetted into triplicate 0.5 ml tissue culture wells (Disposo-Trays, Model 96-SC, Linbro) and incubated at 37 °C in humidified atmosphere of 5% CO_2–95% air. After 5 d of incubation, the clots in the wells were placed on glass slides, fixed with 5% glutaraldehyde and stained with 3,3′-dimethoxybenzidine and Harris haematoxylin[3].

cellulose cultures, showed that mouse marrow cells, previously incubated *in vitro* with purified Rauscher leukaemia virus, develop more erythroid colonies than untreated control cells. Clarke *et al.*[12], using the plasma clot method, observed erythroid colonies 2 d after incubation of mouse marrow cells with culture fluid from Friend virus infected monolayers of fibroblasts. These colonies were similar to EP-induced 2-d colonies in gross morphology and random distribution throughout the clot. Virus-induced bursts were not present in later stages of culture and erythroid colonies were not induced after incubation of marrow cells with plasma from Friend virus infected mice. We now report that when mouse marrow cells are incubated *in vitro* with infectious plasma or tissue culture fluids containing the Friend virus complex, a substantial number of erythroid bursts appear 5 d after the initiation of the cultures. The Friend virus complex consists of at least two biologically active viruses—the spleen focus-forming virus (SFFV) which is replication defective and essential for increased erythropoiesis *in vivo*, and a helper murine leukaemia virus (MuLV-F)[13,14].

The time elapsed between primary infection with Friend virus complex *in vivo* and the peak of haemoglobin synthesis *in vitro* is 4–5 d (ref. 15). The size of the peak depends on the dose of virus and the time after infection at which the cells are placed *in vitro*, but the time course of haemoglobin synthesis is constant. Although these results were obtained in liquid cultures and with ^{59}Fe which was incorporated into haem[15], Friend virus-infected marrow cells might be expected to produce benzidine-positive cells in semi-solid cultures within a period similar to that required for the wave of ^{59}Fe incorporation.

Marrow cells from mice treated with phenylhydrazine to make them anaemic, were incubated with a 1:20 dilution of Friend virus plasma and seeded in plasma clot cultures. A typical 5-d burst is shown in Fig. 1. We observed similar but fewer bursts with marrow cells from normal mice. In contrast to erythroid colonies that appear 2 d after the addition of EP, almost all colonies seen 5 d after the addition of Friend virus complex were in clusters resembling the bursts produced by EP[3,4]. Each cluster consisted of multiple colonies of erythroblasts containing from 8 to more than 100 cells. It has been shown that all the colonies of an EP-induced burst arise from a single cell[16]. Whether the Friend virus complex acts on the same cell that responds to EP with the formation of 5-d bursts remains to be determined.

As shown in Table 1, the number of 5-d bursts decreased progressively as the cells were incubated with increasing dilutions of infectious plasma. A constant association was observed between burst forming ability and focus-forming ability in two separate infectious plasmas and cell culture supernatants from 3 different cell lines producing SFFV. In contrast, burst forming activity was not detected in normal BALB/c mouse plasma or cell culture fluids from cell lines which produced only MuLV.

Two sets of results (Table 1 and Fig. 2) suggest that the development of erythroid bursts after the addition of Friend virus infectious plasma is a direct effect of virus on the marrow cells. First, heat treatment at 56 °C for 1 h rendered Friend virus infectious plasma incapable of inducing splenic foci *in vivo* and producing splenomegaly[5,6,15]. Heat treatment of the infectious plasma either at 80 °C for 3 min or at 56 °C for 1 h abolished the formation of 5-d bursts *in vitro* (Table 1). EP is heat stable[17] and similar treatment did not destroy its ability to induce erythroid colonies from mouse marrow cells after 2 d of culture in the plasma clot system (our unpublished results). Second, Friend virus infectious plasma was layered over a 5–20% linear sucrose gradient, and an EP preparation was layered on an identical gradient (Fig. 2). Both gradients were centrifuged and fractionated. Each fraction of the gradient containing infectious plasma was assayed for its ability to induce 5-d erythroid bursts, and for its content of SFFV and MuLV-F as defined by the spleen focus-forming assay[18] and XC assay[19], respectively. Most of the 5-d erythroid burst-forming activity, as well as XC plaque and spleen focus-forming activities, were recovered in the bottom half of the gradient. There was no activity at the top, where EP would have been located. Thus, erythroid burst formation was produced by an entity that sedimented with the known virus activities in Friend virus preparations. To detect EP activity, fractions of the EP gradient were tested for their ability to induce 2-d erythroid colonies. As expected, many colonies were produced by fractions in the top part of the EP gradient, but only small, background, numbers were produced by lower fractions.

Table 1 Relation of SFFV activity to production of 5-d erythroid bursts

Test preparation	Dilution	Contains SFFV	Contains MuLV-F	Average 5-d bursts per clot
	Expt 1			
M19 plasma	1:20	+	+	23
M19 plasma treated, 56 °C × 1 min.	1:20		ND*	0
M18 plasma	1:20	+	+	30
M18 plasma	1:40	+	+	20
M18 plasma	1:80	+	+	12
M18 plasma	1:160	+	+	9
M18 plasma	1:320	+	+	2
M18 plasma	1:640	+	+	1
M18 plasma treated, 80 °C × 3 min	1:20	–	ND	0
Normal BALB/c mouse plasma	1:20	–	ND	0
	Expt 2			
Tissue culture supernatants:				
SC-1† (M16)	Undiluted	+	+	11
FP52‡	Undiluted	+	+	23
EY26§	Undiluted	+	+	3.6
SC-1 (M16) treated, 56 °C × 60 min	Undiluted	–	ND	0

EY26 treated, 56 °C × 60 min	Undiluted	–	ND	0
SC-1† MuLV-M	Undiluted	–	+	0
SC-1† MuLV-F	Undiluted	–	+	0
1902§ Nonproducer cells	Undiluted	–	–	0

In expt 1, marrow cell suspensions were prepared from mice pretreated with phenylhydrazine as in Fig. 1. The cell suspensions were mixed with the indicated test preparations and incubated as described in Fig. 1. M19, M18 and M16 refer to separate pooled plasmas prepared from Friend virus-infected mice as previously described[15]. In expt 2, marrow was prepared from normal BALB/c mice. EY26 cells are '1902' cells (nonproducer cells that contain SFFV genetic information[22], but do not release virus particles) which were superinfected with cloned murine leukaemia virus to rescue SFFV[22]. FP52 cells were developed by infection of mouse fibroblasts with Friend virus[21]. SC-1 cells[20] were infected with Moloney leukaemia virus obtained from the ATCC MD {SC-1 (MuLV-M)}; M16 Friend virus infectious plasma prepared as previously described[15] {SC-1 (M16)}; or M16 plasma at a dilution that is past the end point of SFFV {SC-1 (MuLV-F)}.

§ A gift from Dr David Troxler[22].

Thus, we have shown that when Friend virus complex is incubated *in vitro* with mouse marrow cells erythroid bursts develop 5 d later. Bursts can also be seen when the clots are removed on days 3–8, and the timing for the optimum number of bursts remains to be determined. The production of erythroid bursts after incubation of haematopoietic cells with infectious plasma provides an *in vitro* method for studying the interaction of the Friend leukemia virus(es) with the target cell(s). Various indirect *in vivo* approaches have been used to define the cells which are the targets for erythroid transformation by the Friend and Rauscher viruses. A direct *in vitro* approach is now possible.

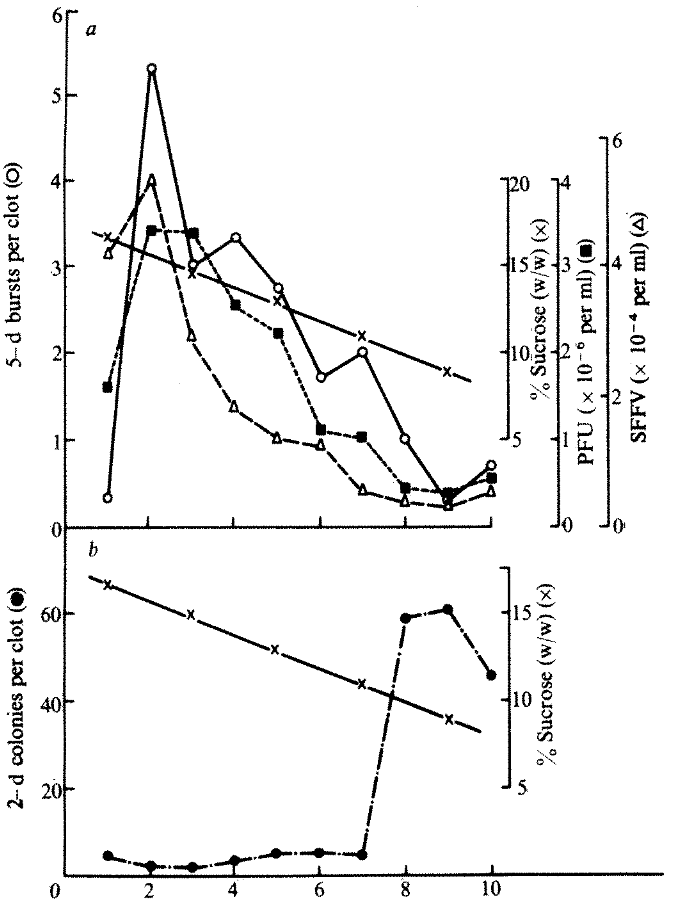

Fig. 2 Recovery of 5-d erythroid burst-forming activity after velocity gradient sedimentation of Friend virus infectious plasma. One ml of infectious plasma was layered over a 4.5 ml 5–20% w/v linear sucrose gradient and centrifuged at 45,000 r.p.m. for 7 min at 4 °C in an SW50.1 rotor. An erythropoietin preparation (EP, Step III, Connaught Medical Research Laboratories) was centrifuged on a similar gradient. Fractions of 0.5 ml were collected from the bottom of both gradients. Marrow cells from phenylhydrazine-treated mice were incubated as in Fig. 1 with each fraction which was diluted 1 : 10 with alpha medium and filtered through 0.45-μm filters. Plasma clots were examined for colonies or bursts at 5 d (*a*) and at 2 d (*b*). In (*a*) the fractions were tested in the spleen focus-forming[18] and XC plaque-forming assays[19].

and experiments are in progress to delineate these cells. This is the first demonstration of the production of erythroid bursts *in vitro* by the Friend virus complex. Because the effect of the virus in our system is quite large (each cluster consists of multiple large colonies) we have now a better means of studying the process of erythroid transformation by a murine virus. It should also be possible to develop a suitable *in vitro* assay for SFFV.

Mutagenesis of Chinese hamster cells is facilitated by thymidine and deoxycytidine

ONE-WAY information transfer from nucleic acids to proteins is generally considered to ensure accurate cell self-duplication, in which errors occur by mutation[1]. However, it has been argued that self-duplication is a multimolecular process consisting of several potentially error-prone stages[2], and that mutation is a complex cellular process[3]. Moreover, it has been shown that error-prone DNA polymerases cause mutations in bacteriophage T_4 (ref. 4.5). We now report that mutations produced by *N*-methyl-*N*′-nitro-*N*-nitrosoguanidine (MNNG), at two separate loci in Chinese hamster cells, are increased 3–10-fold when the cells are treated in the presence of low concentrations ($\sim 2\times 10^{-5}$ M) of thymidine (TdR) and deoxycytidine (CdR). We conclude that imbalanced nucleotide pools facilitate errors of replication of methylated DNA, and suggest that aberrant synthesis of macromolecules, facilitated by imbalances in precursor pools, plays an important part in the expression of genetic damage.

Figure 1*a* shows that in the presence of CdR or TdR (0.5–2.0 μg ml^{-1}) the frequency of ouabain-resistant (Oua^r) colonies induced by MNNG was increased 2–15-fold, the most consistent increase (2.9–3.0-fold) occurring in the presence of equal concentrations of TdR and CdR. Figure 1*b* shows that in the presence of CdR and TdR the frequency of 8-azaguanine-resistant (AzG^r) colonies induced by MNNG was consistently increased 2.7–4.3-fold. However, these nucleosides did not increase the yield of AzG^r or Oua^r colonies that arose spontaneously in the two experiments shown in Fig. 1. The spontaneous frequencies were $\sim 1\times 10^{-5}$ survivors for AzG^r and Oua^r colonies.

Figure 1*c* shows that cytotoxicity of the LD_{50} level of MNNG (1.0 μg ml^{-1}) was greatly increased when cells were grown and treated in dialysed fetal calf serum in the presence of as little as 0.5–2.0 μg ml^{-1} of TdR. This effect did not occur in medium containing the same concentrations of both TdR and CdR. In medium containing CdR in the absence of TdR, MNNG was ~20% less toxic than in medium to which no nucleoside had been added. In the absence of MNNG, CdR and TdR, separately, at concentrations of 0.5–2.0 μg ml^{-1} reduced the plating efficiency by only 7–17%.

The results shown in Fig. 1*a* and *b* are surprising, because cells possess controls to ensure that the DNA replication mechanism selects the correct nucleotides[6]. Therefore, it is necessary to inquire whether the colonies scored for Fig. 1*a* and

0028-0836/78/0276—0508$01.00

b represent increased mutation frequencies, selective toxicity of MNNG for non-mutant cells, selective growth of mutants, decreased time for expression of the mutant phenotypes, or modification of MNNG or its cellular targets in the presence of CdR and TdR. Experiments designed to test these possibilities have been carried out and are summarised below. They will be reported in detail elsewhere.

AzG^r clones have been extensively characterised in previous studies in our laboratory[7,8]. Of 20 AzG^r colonies from V79 cells treated with MNNG in the presence of TdR and CdR (4.0 μg ml^{-1}), 70% showed the AzG^r, HAT (10^{-5}M hypoxanthine, 10^{-6} M aminopterin, 5×10 M TdR) sensitive (HAT^s) phenotype characteristic of hypoxanthine: guanine phosphoribosyl transferase (HGPRT) deficient mutants[7,8], 5% showed the AzG^r, HAT^r phenotype found in mutants containing HGPRT with an altered K_m for substrate[9,10], and 25% were unable to grow to confluence in either AzG or HAT. None of the isolates showed the AzG^s, HAT^r phenotype of the parental non-mutant cells. Therefore, we consider all the colonies that were scored for Fig. 1*b* to be mutants. Of 17 Oua^r colonies isolated, all remained completely resistant to 3 mM ouabain 8 and 35 d after isolation. Therefore, we consider the Oua^r phenotype to be characteristic of mutants containing a modified (Na^+, K^+)ATPase[11,12].

Both in the presence of CdR, or CdR plus TdR, and in their absence, cells treated with 0.5 μg ml^{-1} of MNNG underwent the same number of doublings (3–3.5) before exposure to ouabain or AzG. Moreover, we have measured the AzG^r colony frequency over 12 population doublings in cultures treated with the LD_{50} level of MNNG in the presence or absence of CdR, TdR and CdR plus TdR (2.0 μg ml^{-1}). In those experiments, the mutation frequencies in cultures grown in the presence of CdR and TdR remained three- to seven-fold higher than the frequencies obtained with MNNG alone. These findings show that the increased mutation frequencies produced by CdR and TdR are not the result of differences in expression time.

The doubling time (12.7±0.66 h) of AzG^r colonies isolated from cultures treated with MNNG in the presence of CdR plus TdR was not different from the doubling time (12.4±1.5 h) of AzG^s cells in medium containing CdR plus TdR (2.0 μg ml^{-1}). Therefore, the AzG^r mutants did not have a selective advantage over AzG^s cells in medium containing CdR and TdR.

In the absence of TdR, concentrations of CdR ranging over 0.5–2 μg ml^{-1} produced the same slight (<20%) reduction in MNNG cytotoxicity (Fig. 1*c*), showing that the CdR was not preventing the MNNG from reaching targets for cytotoxicity within the cells.

Moreover, DNA single-strand breaks produced by MNNG were measured using our alkaline sucrose-gradient procedure[13,14]; the extent and also the persistence of the breaks produced in the presence of the CdR plus TdR (2.0 μg ml^{-1} of each) or in the absence of the nucleosides were not significantly different. Therefore, neither CdR nor TdR prevented MNNG from reaching the DNA. Thus, we consider it most unlikely that the effects of the nucleosides on cytotoxicity and mutation result from modification of MNNG or its cellular targets before alkylation occurs. We must therefore conclude that MNNG-induced mutagenesis at two different loci (one, recessive, that involves purine nucleotide metabolism, and the other, dominant, that involves cation transport through the cell membrane) in Chinese hamster V79 cells, was increased three- to four-fold in the presence of 0.5–2.0 μg ml^{-1} of CdR plus TdR. Moreover, we have obtained similar results using *N*-ethyl-*N*′-nitro-*N*-nitrosoguanidine (ENNG) and ethyl methane sulphonate (EMS) as mutagens (A.R.P., H.P. and C.H., unpublished data).

The MNNG-induced mutation frequency increases with increase in the toxicity of MNNG in Chinese hamster cells[7,8,15,16], so the increased mutation frequency observed in the presence of TdR could have been associated with the greatly increased toxicity with TdR (Fig. 1*c*). However, when both CdR and TdR were present, the TdR sensitisation of the cells to the cytotoxicity of MNNG was abolished (Fig. 1*c*), although the

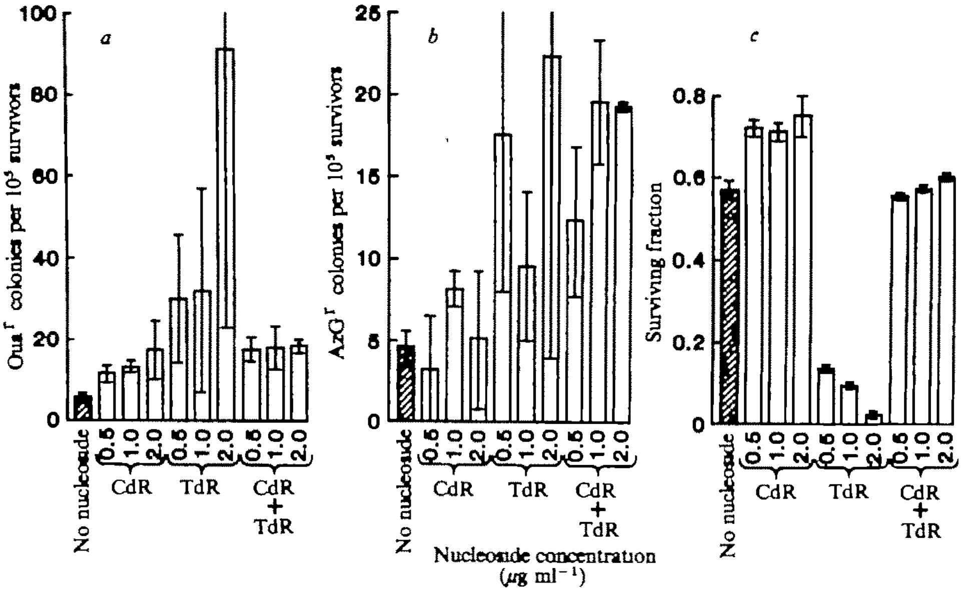

Fig. 1 The induction by MNNG of Oua^r (*a*) and AzG^r colonies (*b*), and the cytotoxicity of MNNG (*c*), in the presence of CdR and TdR in cultures of V79 Chinese hamster cells. For one assay of the induction of AzG^r and Oua^r colonies, 10^5 cells were plated in each of two 100-mm plastic dishes (Corning) in medium of the same composition as used for the cytotoxicity assays. After incubation for 6 h, the cells were treated with 1.0 μg ml^{-1} of MNNG for 2 h, incubated for 48 h in MNNG-free medium containing the indicated supplements of CdR and TdR, trypsinised, replated in fresh medium of the same composition at a density of 0 5–1×10^5 cells per plate in medium containing appropriate supplements, incubated for 24 h, and treated with AzG (40 μg ml^{-1}, 0.26 mM) or with ouabain (3 mM). The cultures were incbubated for 10–12 d with a change of fresh AzG- or ouabain-containing medium supplemented with the indicated levels of CdR and TdR at 5 d. Colonies were fixed, stained and scored 8–10 d later using the same procedures as those used in the cytotoxicity assay. For one assay of cytotoxicity, 200 cells were plated in each of four 55-mm plastic dishes (Corning) in Dulbecco's medium supplemented with 10% dialysed fetal calf serum (DS) (Gibco), or in DS plus various concentrations of TdR and CdR The dishes were incubated for 6 h at 37 °C in a humidified atmosphere of 10% CO_2 in air. Some dishes received 1.0 μg ml^{-1} of MNNG from a stock solution in acetone, others, controls, received 0 25% acetone. After a 2-h incubation, the medium was aspirated and replaced with fresh medium free of MNNG, but containing the supplements of CdR and TdR The cultured were then incubated for 7–9 d, fixed, stained with Giemsa, and the colonies were counted. Only colonies with diameters of 0 5 mm or more were scored using a Biotran automatic colony counter (New Brunswick Scientific). Mutation frequencies (*F*) were calculated by the formula:

$$F = \text{total mutant colonies}/(\text{total cells replated} \times \text{plating efficiency of replated cells}),$$

and also by applying Poisson statistics as described in ref. 29. Both methods of calculation gave essentially the same results The results shown here are the means and ranges of two assays.

yield of Oua^r and AzG^r colonies was reproducibly three- to four-fold greater than with MNNG alone (Fig. 1*a*, *b*).

It is well established that exogenous TdR and CdR, supplied to cell cultures in concentrations of the order of 10^{-5} M (~2.0 μg ml^{-1}) produce an imbalance of the deoxyribonucleotide pools in many lines of mammalian cells, including Chinese hamster ovary cells[17,18]. Moreover, recent studies in cell-free systems show that the fidelity of DNA replication decreases as the relative concentration of incorrect nucleotides increases in the reaction mixture[19]. Therefore, we offer the following interpretation of our data: in V79 cells the imbalance produced in nucleotide pools by the uptake of exogenous TdR and CdR facilitates aberrant replication of DNA alkylated by MNNG, ENNG and EMS. Some errors are lethal, others are mutagenic. The lethal errors are facilitated by TdR, but not by CdR; the mutagenic errors are facilitated by both TdR and CdR.

Our interpretation seems at first to be incompatible with the fact that living systems possess vital 'proof-reading' mechanisms which ensure high fidelity of DNA replication[6]. However, it can be argued that mechanisms which promote infidelity in response to life-threatening environments will be advantageous to living organisms. Radman[20] has proposed such an 'S.O.S.' mechanism; it is considered to operate by mutagenic DNA repair induced in response to genetic damage.

Evidence for a mechanism that need not involve DNA repair, for producing infidelity in DNA replication, is provided by our data (Fig. 1), and by experiments showing increased mutation in Chinese hamster cells grown in medium containing high (4×10^{-3} M) concentrations of thymidine[21], and thymine-starved bacteria[22,23], and yeast[24], which show that DNA synthesis is increasingly error prone when the pools of DNA precursors become unbalanced.

DNA is not the only macromolecule whose synthesis can be made error prone by unbalancing its precursor pools. Starvation of amino acids leads to severe translational errors in bacterial and animal cells[25]. Bujard and C.H.[26] found that *in vitro* transcription of synthetic DNA templates by *Escherichia coli* RNA polymerase became error prone in the presence of 4×10^{-4} M uridine triphosphate, which by nearest-neighbour analysis was shown to be incorporated into RNA in place of cytidine triphosphate. Thus, not only the synthesis of DNA, but also those of RNA and protein can be error-prone in the presence of unbalanced precursor pools, and we propose that such errors could become manifested as substantial alterations in gene expression. The accumulation of copying errors in macromolecule synthesis has been suggested as a mechanism for ageing[27], and has been implicated in mutagenesis and carcinogenesis[15,28]. We consider it likely that errors in DNA, RNA and protein synthesis, facilitated by imbalances in precursor pools, are not only involved in carcinogenesis, mutagenesis and ageing, but have also played a part in the evolution of species.

Transformed cell lines susceptible or resistant to *in vivo* surveillance against tumorigenesis

THE transformation of a normal cell to one which grows as a cancer requires several steps, one of which may involve the escape from tumour surveillance[1]. We describe here an experiment designed to define these steps more clearly. The principle is to transform normal continuous cell lines *in vitro* and then select for transformants by their growth in agarose[2,3]. These procedures avoid any host selection. By testing the tumorigenicity of these cloned, transformed cell lines in normal and immunodeficient mice, it would be possible to estimate the frequency of transformation resulting in tumorigenic clones and the proportion of these clones that is rejected by normal mice. Based on their tumorigenic potential, we have divided these cells into three classes (Table 1), 0, I, and C. 0 cells, although able to grow in agarose, do not form tumours in either test animal. I cells form tumours only in immunodeficient mice and C cells form tumours in both types of mice. The existence of 0 and I cells indicates that at least one additional mutation is required for these cells to grow as a cancer (C).

Table 1 Classification of cells by growth in agarose and mice

Type	Colony formation in agarose	Growth as tumour in Immune deprived mice	Growth as tumour in Normal mice
N	−	−	−
0	+	−	−
I	+	+	−
C	+	+	+

N cells were grown in Dulbecco's modified Eagle's minimum essential media (DME) plus 10% fetal bovine serum (FBS). These cells were treated with either virus (SV-40 or Abelson murine leukaemia virus) or chemicals (20-methylcholanthrene; *N*-methyl-*N*-nitro-*N*-nitrosoguanidine; 11,12-dihydro-3-methylcholanthrene-11,12-epoxide; or 5,6-dihydrobenz(*a*)anthracene-5,6-epoxide). 24 h later these cells were plated in 0.3% agarose containing DME plus 25% FBS at 10^5, 10^4 and 10^3 cells per 60-mm plate. The plates were incubated at 37 °C until macroscopic colonies appeared, but no longer than 8–12 weeks. Colonies were picked from the agar and grown in DME plus 10% FBS. 5 or 10×10^6 cells were injected subcutaneously into normal mice and mice which had been thymectomised as adults, lethally irradiated (750 rads) and restored with 10^7 syngeneic fetal liver cells (AT×FL).

0028–0836/78/0276—0510$01 00

Table 2 Distribution of transformed clones characterised by inoculation into normal and AT×FL mice

Transforming agent	Classification of transformed clones			Efficiency of rejection*
	0	I	C	
Viral	14% (2/14)	64% (9/14)	21% (3/14)	75% (9/12)
Chemical	10% (2/21)	19% (4/21)	71% (15/21)	21% (4/19)

The distribution of chemically transformed clones into the 0, I or C categories differs significantly ($P \leq 0.005$)[7] from the distribution of the virally transformed clones.

* Efficiency of rejection = no. of I clones/no. of I+C clones.

Cloned, continuous lines of normal fibroblast cells (N cells) were derived from BALB/c, BALB.B and C57BL/6 embryo cultures. These cells do not form colonies in agarose or grow as tumours even in immunodeficient mice (thymectomy, lethal irradiation and fetal liver restoration of adults; AT×FL). N cells were transformed with either viral or chemical carcinogens (Table 1) and colony formation in agarose was used to select for transformed variants.

As shown in Table 2, 35 independently derived transformed clones were tested for their tumorigenicity in syngeneic normal and immunodeficient mice. Of the 35 cell lines, 14 were derived following viral transformation and 21 were obtained after chemical carcinogenesis. Overall, 31 of 35 clones isolated from agarose formed tumours in AT×FL mice (that is, I+C lines), indicating a high correlation (89%) between *in vitro* growth in agarose and *in vivo* tumorigenicity. The 10–14% of transformed clones which were classified as 0 may represent a class of cells which are either inherently nontumorigenic or which are susceptible to surveillance mechanisms remaining in AT×FL mice. The collection of 0 lines is now being tested for tumorigenicity in mice which have been rendered deficient in other possible surveillance mechanisms.

From the data shown in Table 2, we can calculate that the proportion of tumorigenic transformed cell lines falling into the I-cell category was 9/12 (75%) for the virally transformed lines and 4/19 (21%) for the chemically transformed lines. Expressed in terms of the efficiency of surveillance, 75% of the viral and 21% of the chemically transformed cell lines were susceptible to a surveillance mechanism which is impaired in the AT×FL mouse. Although the AT×FL mouse is severely depleted of T-cell activity, and therefore, immunodeficient[4–6], these animals also have lower levels of natural killer (NK) cell activity. It is tempting to speculate that these deficiencies allow the growth of I lines.

We have not confirmed that all C lines are derived from I-type intermediates as predicted in the N → I → C sequence required by surveillance models. However, it is clear that clones which have undergone the mutation N → I require another mutation, I → C, to grow as a tumour in normal mice. We have several examples where this has occurred.

There are three potential sources of error in categorising I lines. First, the 0 lines could, in fact, be I lines if the AT×FL mouse had residual tumour resistance. Second, if N lines had acquired rejection antigens before transformation, these antigens could result in overestimation of the frequency of I lines; however, the high frequency of C lines makes this unlikely. Third, the transformed clones were tested at 10^7 cells per animal for classification of tumour potential. If surveillance against tumours is of any physiological importance, the system must be capable of eliminating tumour cells when they are in relatively low numbers (certainly less than the test dose of 10^7). At the test dose, efficiency of rejection could have only been underestimated.

To our knowledge, this is the only experiment in which the frequency of appearance of the postulated N → I step has been evaluated by the isolation of transformed clones in the absence of an immune system (that is, *in vitro*) and by testing them simultaneously in immunodeficient (AT×FL) and normal mice. The existence of I cells shows that a host protective mechanism is operative. Although the difference between viral and chemical carcinogenesis seems large, the above sources of error would lead to an underestimation of the efficiency of this host protective mechanism. The resolution of these limitations may only decrease the difference. Consequently, we conclude that immune protective mechanisms have a significant but not absolute role in tumorigenesis.

Influence of cyclic AMP on intracellular *p*H regulation and chloride fluxes in barnacle muscle fibres

THE *p*H sensitivity of numerous intracellular processes requires the close regulation of internal *p*H (pH_i). As the pH_i of many cells is maintained at a higher value than it would have if H^+ were at equilibrium across the cell membrane, it follows that the acidifying effects of cellular metabolism and of passive H^+ influx and HCO_3^- efflux must be balanced by active acid extrusion. It is now generally accepted that this extrusion is stimulated by decreases in pH_i, and that, in several cells, it is accomplished by exchanging external HCO_3^- for internal Cl^- (refs 1–4). Recently, a role for cyclic 3′,5′-adenosine monophosphate (cyclic AMP) in pH_i regulation was suggested by the observation that dibutyryl cyclic AMP attenuates the CO_2-induced fall of pH_i in mammalian cardiac muscle[5]. We now report experiments on the effects of cyclic AMP on acid extrusion and on accompanying Cl^- fluxes in the barnacle muscle fibre, a preparation known to contain cyclic AMP (ref. 6). Our data show that internally applied cyclic AMP enhances the response of the pH_i-regulating system to acid loads.

The experiments were carried out on superfused single muscle fibres of the giant barnacle (*Balanus nubilus*). Intracellular *p*H and concentrations of low molecular weight solutes were controlled by insertion of a porous dialysis capillary through the fibre, and perfusion with fluid[7]. In one series of experiments, pH_i was monitored by placing *p*H-sensitive and reference microelectrodes into the fibre alongside the dialysis tube. In another series, either Cl^- influx or efflux was measured with ^{36}Cl.

The influence of cyclic AMP on the rate of acid extrusion was examined as shown in Fig. 1*A*. The fibre was loaded with acid by dialysing with a cyclic AMP-free solution at *p*H 6.0 (Fig. 1*A*, segment *ab*); to reduce acid extrusion rate while acid loading, external *p*H (pH_o) was simultaneously lowered from 7.8 to 6.8 (ref. 8). When pH_i had fallen to 7.02 (Fig. 1*A*, point *b*), dialysis was halted so that acid no longer entered the cell by this route, and pH_o was returned to 7.8. In the absence of cyclic AMP, pH_i recovered at a low rate (Fig. 1*A*, segment *bc*). However, when the fibre was dialysed with an acid solution containing cyclic AMP (Fig. 1*A*, *cd*), pH_i recovered nearly four times faster (Fig. 1*A*, *de*). This recovery was blocked (Fig. 1*A*, *fg*) by SITS (4-acetamido-4′-isothiocyanostilbene-2,2′-disulphonic acid), a potent inhibitor of acid extrusion[1,4,9]. Figure 1*B* shows the effect of cyclic AMP on the dependence of acid extrusion rate on pH_i. Although cyclic AMP had little effect at the normal pH_i of 7.3, it greatly increased acid extrusion rate at low pH_i. In these experiments, a high (20 μM) dialysate level of cyclic AMP was used to maintain adequate cytoplasmic levels after dialysis was halted. Even so, the stimulatory effects of the nucleotide faded within 10–20 min unless 3-isobutyl-1-methylxanthine, an inhibitor of cyclic AMP hydrolysis, was added. However, even 1 μM cyclic AMP was able to increase acid extrusion rate when dialysis was continuous, as shown in Fig. 1*C*. Here, dialysis with fluid at *p*H 6.6 caused pH_i to fall (Fig. 1*C*, *ab*) until the entrance of acid by dialysis was balanced by acid extrusion (Fig. 1*C*, *b*). When 1 μM cyclic AMP was now added to the dialysate, pH_i rose by 0.1 (Fig. 1*C*, *bc*), reflecting stimulation of the acid extrusion rate. Exposure to the diuretic furosemide (0.6 mM), an inhibitor of anion transport[10], caused a decline in pH_i (Fig. 1*C*, *cd*), indicating inhibition of acid extrusion.

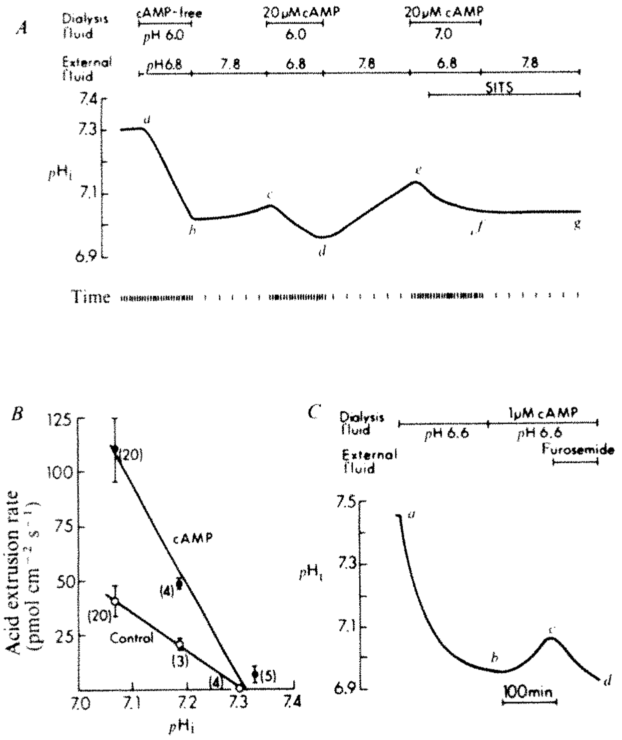

Fig. 1 *A*, Effect of cyclic AMP (cAMP) on acid extrusion. The pH_i was lowered by dialysing, first with cyclic AMP-free (segment *ab*) and then cyclic AMP-containing (*cd*, *ef*) fluid (50 mM HEPES buffer). On halting dialysis, the subsequent recovery of pH_i, which reflects acid extrusion, was slow in the absence of cyclic AMP (*bc*), but much faster in its presence (*de*). SITS (0.5 mM) blocked recovery, even with cyclic AMP (*fg*). Membrane potential (V_m) was −49 mV at the onset of the experiment and −48 mV at the end. The speed of the strip-chart recorder was increased fivefold during the periods of pH_i recovery; each hash mark represents 2.5 min. *B*, Effect of cyclic AMP on the acid extrusion rate at various values of pH_i. Data were derived frpm experiments similar to that above. Values of the acid extrusion rate were calculated from observed d*pH*/d*t* (during pH_i recovery) and measured intracellular buffering power, assuming that the fibre is a cylinder. Vertical bars indicate one standard error; number of experiments given in parentheses. Lines through points represent least-square fits. *C*, Effect of cyclic AMP on pH_i in a continuously dialysed fibre (pH_o = 7.8). During dialysis, pH_i is determined by the balance between introduction of acid by dialysate (*p*H 6.6, 50 mM PIPES buffer) and acid extrusion by the pH_i-regulating system of the cell. Addition of 1 μM cyclic AMP to the dialysate causes a 0.1 increase in steady-state pH_i (compare *b* and *c*), reflecting a stimulation of acid extrusion, which is blocked by the addition of 0.6 mM furosemide (Hoechst) to the external fluid (*cd*). V_m = −48 mV. Unless otherwise indicated, artificial sea water contained (in mM): 418 NaCl, 10 KCl, 11 $CaCl_2$, 32 $MgCl_2$ and 30 HEPES, and was gassed with 100% O_2. Although this solution was nominally HCO_3^--free, $[HCO_3^-]_o$ in the vicinity of the muscle fibre was probably ~1 mM (W.F.B., McCormick and A.R., unpublished). Dialysis fluid contained (in mM): 30 KCl, 160 K glutamate, 20 Na glutamate, 4 $MgSO_4$, 550 mannitol, 0.5 EGTA, 0.5 phenol red and 50 mM HEPES or PIPES. Temperature was 22 °C.

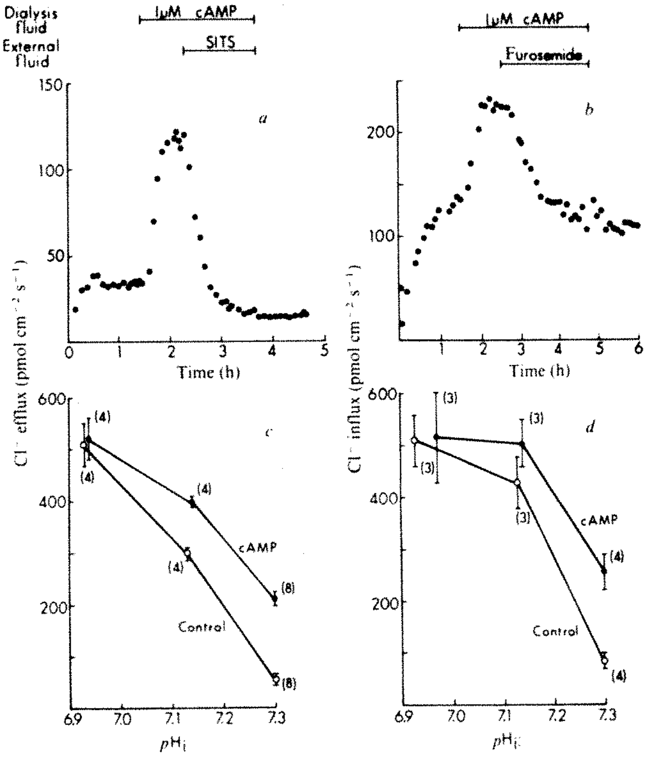

Fig. 2 *a*, Effect of cyclic AMP on Cl^- efflux. At time zero, flow of isotope-containing dialysis fluid, *p*H 7.3 (50 mM HEPES buffer) was begun. After Cl^- efflux had reached a steady state, 1 μM cyclic AMP was added to the dialysis fluid, causing an increase in Cl^- efflux. Subsequent addition of 0.5 mM SITS to the external fluid reduced Cl^- efflux to slightly below control values. V_m was −53 mV at the outset and −49 mV at the end of the experiment. *b*, Effect of cyclic AMP on Cl^- influx. After Cl^- influx had reached a steady state, addition of 1 μM cyclic AMP to the dialysis fluid caused an increase in Cl^- influx which was then reversed by the presence of 0.6 mM furosemide in the external fluid. V_m was −51 mV and −47 mV at the beginning and end of the experiment, respectively. *c*, *d*, Effect of cyclic AMP on Cl^- efflux and influx at various values of pH_i. Experiments were similar to those above. Vertical bars represent one standard error; number of experiments is given in parentheses. Lines through points drawn by hand. Actual values of pH_i were verified with *p*H microelectrodes (see Fig. 1*C*) in separate experiments; 4–5 determinations of pH_i were made for each *p*H of the dialysis fluid; s.e. = ±0.03–0.04.

Evidence that acid extrusion involves an exchange of external HCO_3^- for internal Cl^- (refs 1, 2), and the effect of cyclic AMP on acid extrusion, suggested that cyclic AMP would stimulate Cl^- efflux. Figure 2*a* and *b* shows that dialysis with 1 μM cyclic AMP stimulated not only Cl^- efflux, but also its influx. These effects could be blocked by either SITS or furosemide. Lowering pH_i stimulated efflux and influx (as it did acid extrusion rate),

Table 1 Dependence of Cl^- influx and rate of acid extrusion on $[HCO_3^-]_o$ at different values of pH_i

pH_i	Cl^- influx (pmol cm^{-2} s^{-1})		Acid extrusion rate (pmol cm^{-2} s^{-1})	
	$[HCO_3^-]_o$ = 0	$[HCO_3^-]_o$ = 6 mM	$[HCO_3^-]_o$ = 0	$[HCO_3^-]_o$ = 6 mM
7.30	51±2 (3)	48±1 (3)	0	12±8 (6)
7.13	455±44 (3)	310±23 (3)	32±8 (4)	171±32 (6)
6.93	512±46 (3)	351±44 (3)	101±18 (4)	436±110 (3)

External solutions (pH_0 = 7.8) contained either nominally 0 mM HCO_3^- (gassed with 100% O_2) or 6 mM HCO_3^- (gassed with 0.4% CO_2, balance O_2); all solutions contained 30 mM HEPES. In acid extrusion experiments, fibres were acid loaded using the NH_4Cl prepulse technique[8]. The values are means ± s.e.; numbers of experiments in parentheses.

and these responses were further enhanced by cyclic AMP (Fig. 2*c*, *d*). Cyclic GMP did not significantly alter Cl^- efflux or influx, or the acid extrusion rate.

At pH_i 7.3, cyclic AMP stimulated both unidirectional Cl^- fluxes (Fig. 2*c*, *d*), whereas it had little effect on acid extrusion (Fig. 1*B*), that is, net HCO_3^- influx. As these increases in Cl^- efflux and influx are of similar size (~160 pmol cm^{-2} s^{-1}), it is likely that, at pH_i 7.3, cyclic AMP enhances a Cl–Cl exchange. The existence of a Cl–Cl exchange at pH_i 7.3 is supported by the requirement of Cl^- influx for internal Cl^- (J.M.R. and M.S.B., unpublished), and by our observation that, with or without cyclic AMP, Cl^- efflux and influx were inhibited to a similar extent by either SITS or furosemide. Our data indicate that reducing pH_i below 7.3 enhances an existing Cl–Cl exchange (Fig. 2*c*, *d*) and, in addition, initiates a HCO_3–Cl exchange, that is, acid extrusion (Fig. 1*B*). Both these exchanges were stimulated by cyclic AMP. The common sensitivity, at low pH_i, of the Cl–Cl and HCO_3–Cl exchanges to cyclic AMP, SITS and furosemide suggests that both exchanges are mediated by the same carrier. If this is the case, then HCO_3^- and Cl^- might compete for entry. This expectation is confirmed in Table 1. At pH_i 7.3, when the acid extrusion rate was zero and the exchange mechanism was in the Cl–Cl mode, increasing $[HCO_3^-]_o$ had little effect on either acid extrusion rate or Cl^- influx. However, at lower values of pH_i, raising $[HCO_3^-]_o$ not only increased the acid extrusion rate, but also decreased Cl^- influx. We suggest that pH_i regulation in barnacle muscle is accomplished by an anion exchange mechanism whose rate is enhanced by cyclic AMP and by decreases in pH_i. At pH_i 7.3, this exchange operates at a low rate in the Cl–Cl mode. At lower pH_i, the rate of exchange increases, and simultaneously the mode of exchange shifts from Cl–Cl to HCO_3–Cl. Cyclic AMP increases the rate of anion exchange in either mode, thereby promoting the fluxes of both HCO_3^- and Cl^-.

Our observations concerning the effects of cyclic AMP on pH_i regulation may have implications for any cell subjected to acid loads. Mammalian cells are of particular interest because their high metabolic rate and presumed large HCO_3^- efflux represent a sustained acid load, comparable with that in the acid-dialysed barnacle muscle fibre of Fig. 1*C*. Thus, hormones which increase cyclic AMP levels might raise pH_i, and thereby affect a variety of processes, with the pH_i changes serving as a third messenger.

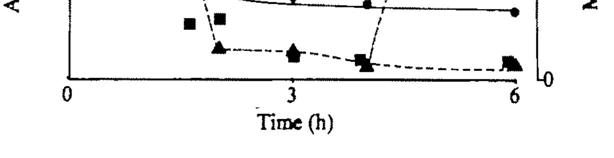
Influence of ATP and calcium on the cortical reaction in sea urchin eggs

THE prevention of polyspermy in the sea urchin egg is a two-stage process: a rapid reduction in the chances of refertilisation—the 'fast block'[1,2], which seems to be electrical in nature[3]—and a slower block that coincides with elevation of a morphological barrier, the fertilisation membrane. The fast block has many features in common with the action potential of excitable tissues, while elevation of the fertilisation membrane seems to involve a classical exocytotic reaction similar to that found at nerve terminals. Lying immediately beneath the plasma membrane of unfertilised eggs is an array of vesicles called cortical granules each about 1 μm in diameter. Shortly after fertilisation the contents of these granules are expelled, the granule membrane becoming incorporated into the plasma membrane of the egg. The trigger for initiating the cortical reaction seems to be a rise in intracellular ionised calcium. Thus granule release can also be promoted by the ionophore A23187 (ref. 4) and measurements in aequorin-loaded fish and sea urchin eggs[5,6] show that exocytosis brought about by both sperm

Fig. 1 Influence of cyanide on the cortical reaction and level of ATP in eggs of *Echinus esculentus* at 16 °C. ●, ○ ATP content of eggs treated at zero time with 5 mM cyanide in artificial seawater containing (mM) NaCl, 465; $MgCl_2$, 55; $CaCl_2$, 11; KCl, 10; $NaHCO_3$, 2.5 pH 7.8. ATP was assayed fluorimetrically[8]. Fertilisation membrane elevation in response to sperm (▲, △) and the ionophore A23187 (20 μg ml^{-1}) (■, □) is also shown. After 4 h cyanide was removed from an aliquot of poisoned eggs by thorough washing (○, △, □).



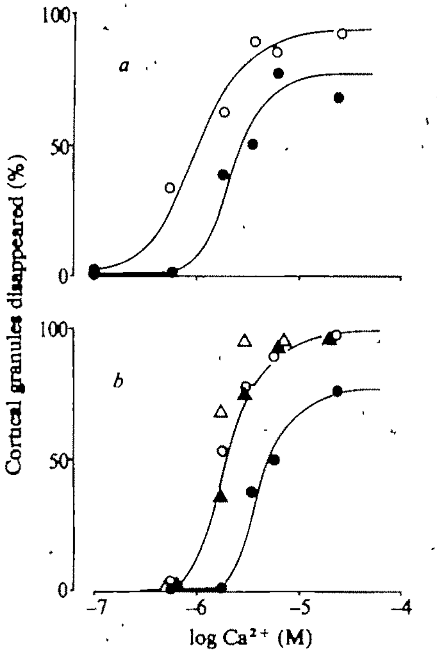


Fig. 2 Dependence of the cortical reaction in broken eggs of *Echinus esculentus* on ionised calcium at 16 °C. *a*, Eggs subjected to a high voltage discharge (1 kV cm^{-1}, $\tau = 50$ μs)[10] in a medium containing (mM): potassium glutamate, 250, glycine, 500, NaCl, 10; $MgCl_2$, 10; HEPES 10, *p*H 6.7. The ionised calcium concentration was controlled with 10 mM EGTA, the abscissa representing values calculated from the stability constants[11]. Thirty seconds after shocking, the eggs were fixed with 4% formaldehyde[2] and the number of cortical granules scored by high-power phase contrast microscopy. ○, Control eggs; ●, eggs treated for 4 h with 5 mM cyanide. *b*, eggs attached to glass or plastic with poly-L-lysine (1 mg ml^{-1}) and broken in the artificial ooplasm described in (*a*). The portion of egg cortex left on the support could be scored at 30 s for the number of cortical granules reacted. ○, Control eggs; ●, cyanide-poisoned eggs. Some eggs were broken in an artificial ooplasm containing 10 mM ATP: △, Control eggs; ▲, cyanide-poisoned eggs. Each point represents a separate experiment on cortices prepared from the same batch of eggs. The reproducibility of individual observations was better than ±10%.

and ionophore is associated with a rise in intracellular ionised calcium. The mechanism of exocytosis in any system is unknown and the cortical granule reaction in sea urchin eggs seems to provide an excellent experimental preparation for its investigation. Here we examine the influence of metabolic poisons and calcium on the cortical reaction. In the presence of ATP exocytosis is activated by micromolar concentrations of calcium; but in the nominal absence of ATP the exocytotic process slowly becomes refractory to calcium.

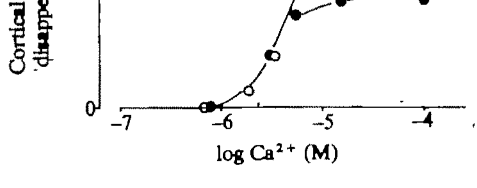
Eggs of *Echinus esculentus* were used and the methodology was as described previously[2]. Figure 1 shows results obtained with intact eggs. The metabolic poison cyanide reversibly blocks cortical granule release and fertilisation membrane elevation in response to both sperm and ionophore. These effects do not result from an action of cyanide *per se* on the activating agent because control eggs elevate normal membranes when exposed to sperm or ionophore in cyanide. Essentially similar results have been obtained with dinitrophenol (DNP) (0.2 mM, *p*H 7.0)[7]. Also, the onset of inhibition of cortical granule release closely parallels a fall in energy-rich phosphate compounds in the egg.

These observations on poisoned eggs can be explained in a number of ways—for example, poisoning may deplete the cell of something essential for activation, or increase the level of an inhibitor. To investigate these possibilities we examined the cortical reaction under controlled conditions using two partially broken egg preparations. In the first, rapid access to the interior of the cell was obtained by exposing suspensions of eggs to a high-voltage discharge[9,10]. Eggs were suspended in a medium similar to ooplasm. If Ca^{2+} is present in the medium at the time the shock is delivered, unpoisoned eggs subsequently undergo cortical granule release and raise a fertilisation membrane; but this response is not seen in EGTA. This technique is a modern version applicable to populations of cells of the 'pricking' technique used by many early workers to activate eggs. Figure 2 shows that the buffered Ca^{2+} concentration required to effect the release of half the cortical granules in unpoisoned eggs is close to 1 μM. This value is more than an order of magnitude lower than the only other reported measurement[6]. Also shown are the results of applying the high-voltage technique to fully-poisoned eggs. Rather surprisingly both cortical granule release and fertilisaton membrane elevation can be fully activated; but the concentration of Ca^{2+} required to effect the release of half the granules, 3 μM, is somewhat higher than in unpoisoned eggs.

Another broken cell preparation has been described by Vacquier[12]. Eggs are attached to a surface by protamine sulphate and subjected to a shearing force. The eggs break leaving small portions of egg cortex attached to the surface. These portions of cortex respond to Ca^{2+}; but are reported to undergo granule–granule fusion. We have found that if the technique is modified by attaching jelly-free eggs either directly to plastic or to a surface coated with poly-L-lysine[13] and the eggs broken in the medium described above, the resulting portions of egg cortex are activated in the same range of Ca^{2+} concentrations as eggs broken by shocking and the appearance of the reacted cortices is entirely consistent with exocytosis, that is, granule–plasma membrane fusion. Isolated cortices prepared from cyanide-poisoned eggs resemble 'shocked' eggs in that they need a higher Ca^{2+} concentration to activate cortical granule discharge. Addition of ATP (10 mM) to these cortices without a change in *p*H restores a Ca^{2+}-sensitivity close to that of unpoisoned eggs. Figure 2 also shows that inclusion of this concentration of ATP in the medium used to prepare cortices from unpoisoned eggs gives the highest apparent affinity of the cortical response for calcium which is very similar to that found in 'shocked' eggs.

The difference in apparent affinity between eggs subjected to a high-voltage discharge (Fig. 2*a*) and eggs broken (Fig. 2*b*) in Ca^{2+}–EGTA solutions containing no ATP emphasises the dependence of the Ca^{2+}-affinity of the cortical reaction on the levels of nucleotide. The high-voltage technique allows rapid access of the Ca^{2+} buffers into the egg, while maintaining sufficient integrity to retain some ATP and ATP-regenerating systems. Breaking the egg removes the cortex from the remainder of the egg and one would expect the local ATP concentration to be much lower as a consequence. Despite the lower Ca^{2+}-affinity in eggs broken in the absence of ATP, the cortical reaction is comparable to that of unpoisoned 'shocked' eggs in

Fig. 3 Dependence of cortical granule exocytosis on ATP at 14 °C. Portions of cortex stuck to glass coverslips with poly-L-lysine and isolated in a nominally Ca^{2+}-free medium containing 1 mM EGTA and 5 mM ATP were superfused with ATP-free medium for 10 min (○) or 30 min (●) before exposure to calcium. The ordinate is the proportion of cortical granules that had disappeared 30 s after the solution had been changed to one containing calcium.



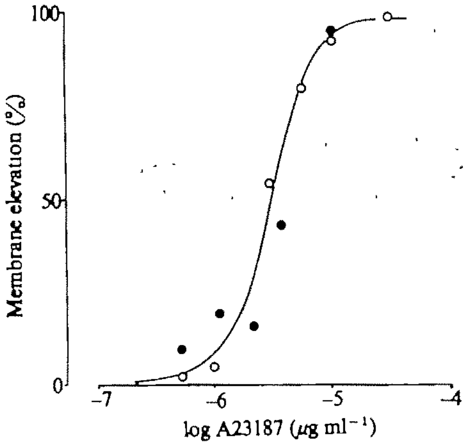


Fig. 4 Concentration–response curve for the ionophore A 23187 in ASW (○), and in Ca^{2+}-free ASW containing 5 mM EGTA (●) at 16 °C. Membrane elevation was scored 3 min after addition of ionophore.

that it proceeds to completion. This contrasts with the cortical reaction of cyanide-poisoned eggs where, in addition to a shift in Ca^{2+}-affinity, some other change seems to have taken place because relatively high (100 μM) levels of Ca^{2+} are unable to effect the release of a proportion (about 15%) of the cortical granules. This effect can be mimicked in isolated cortices by superfusing for various times with nominally ATP-free solutions containing a buffered ionised calcium concentration of less than 10^{-7} M. Subsequent readmission of Ca^{2+} after exposure to ATP-free media for 10 and 30 min triggers appreciable exocytosis (Fig. 3). It is, however, noticeable that although the apparent affinity of exocytosis for Ca^{2+} remains constant, the fraction of granules released falls progressively and the unreleased granules are refractory to very high (0.5 mM) concentrations of calcium. Control cortices exposed for 30 min to Ca^{2+}-free media containing ATP subsequently respond normally to calcium. These results imply that a supply of free ATP is not necessary for exocytosis in this preparation; but the progressively increasing number of cortical granules that fail to respond to Ca^{2+} after prolonged exposure to ATP-free media suggests that tightly-bound ATP, or something derived from it, is necessary either to energise exocytosis or to confer Ca^{2+}-sensitivity on it. After prolonged exposure of isolated cortices to ATP-free media, readmission of ATP restores the high affinity of the exocytotic reaction for Ca^{2+} but fails to restore Ca^{2+}-sensitivity to the refractory granules.

Although there is a slow onset of refractoriness in the cortical response of poisoned eggs, cortices isolated from eggs in which the cortical reaction to sperm and ionophore is completely blocked still react when challenged with quite low concentrations of calcium. This is a rather surprising observation because ionophore, in particular, might be expected to promote Ca^{2+} entry across the plasma membrane until the threshold for exocytosis is reached. That this may not be so is suggested by the data in Fig. 4 which show that there is virtually no difference in the ability of ionophore to activate unpoisoned eggs in normal and Ca^{2+}-free seawater containing EGTA and measurements of ^{45}Ca^{2+} influx show very little stimulation by ionophore. As measurements with aequorin show that ionophore increases intracellular ionised calcium[5], the source of this Ca^{2+} must be intracellular. In seeking an explanation for these results it should not be forgotten that poisoned eggs may contain a potent inhibitor of the cortical reaction, but another attractive possibility is that the cortical reaction in intact eggs involves the release of Ca^{2+} from an internal store. The data here might be explained if this store only remains filled in the presence of ATP. In the absence of this store, ionophore would not be able to generate a sufficient rise in ionised calcium in the vicinity of the cortical granules to initiate exocytosis. This suggestion finds some support in the finding that isolated cortices bind ^{45}Ca^{2+}. This binding is ATP-dependent, is much larger in cortices with intact cortical granules than in cortices that have undergone the cortical reaction, and is much reduced in the presence of the calcium ionophore A 23187.

There is another difference in the response of egg cortices prepared from unpoisoned and poisoned eggs. The response to low concentrations of Ca^{2+} in cortices prepared from unpoisoned eggs often starts at one or a few points—usually near the edge of the torn piece of cortex—and spreads in a wave or waves across the preparation. This is never seen in cortices prepared from poisoned eggs where the cortical granules respond in an apparently random fashion. This propagation reaction seen in unpoisoned cortices may also be related to the existence of a labile calcium store. Thus a rise in ionised calcium at one point may promote release of calcium from the store in a way analogous to calcium-dependent release of calcium in the sarcoplasmic reticulum[14]. Treatment of isolated cortices with ionophore in the presence of EGTA should deplete any membrane-bound stores of calcium and permit examination of cortical granule release in the absence of the presumed store. The cortical reaction of cortices prepared from unpoisoned eggs and treated in this way closely resembles that of cortices prepared from poisoned eggs except that addition of ATP fails to induce the high calcium sensitivity characteristic of unpoisoned eggs. These findings with ionophore-treated cortices support the concept of a store but raise the possibility that the rapid shift in affinity for calcium induced by ATP may be a property of the store and not of the exocytosis reaction itself and suggest that the existence of a store of releasable calcium may be a complicating factor in studies of calcium-dependent exocytosis in this preparation.

Novel cytochrome *b* system in phagocytic vacuoles of human granulocytes

NEUTROPHIL granulocytes are the most numerous leukocytes and have a primary microbicidal role. They are the first cells to accumulate at sites of inflammation where they engulf, kill and digest microbes. The phagocytic process is accompanied by a burst of oxygen consumption which is important for the killing of certain bacteria, as the ability to kill bacteria is impaired in anaerobic conditions[1]; in chronic granulomatous disease (CGD) this enhancement of oxygen consumption is distinctively lacking[2]. The burst of oxygen metabolism is not inhibited by cyanide

0028-0836/78/0276-0515$01.00

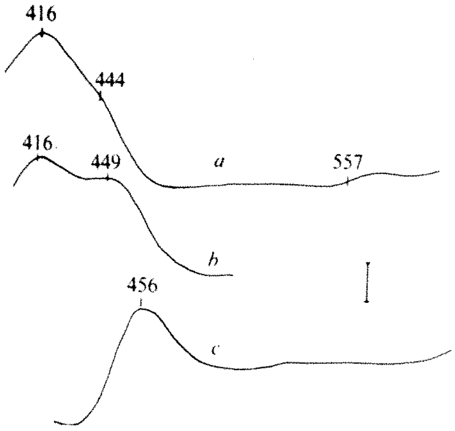

Fig. 1 Difference spectra of human neutrophils incubated with latex particles (*a*), latex particles in the presence of (2 mM) KCN (*b*) or phorbol myristate acetate (*c*). Absorbance scale = 0.028 of full scale for *a* and *b* and 0·011 for *c*. Spectra were determined in the few minutes after mixing 10^8 purified neutrophils[5] in 3 ml of Hanks BSS with 2.5×10^9 latex particles preopsonised with human IgG (ref. 12) or with 7.5 μg of phorbol myristate[13] in 10 μl DMSO.

or azide[3], distinguishing it from mitochondrial respiration by these cells which contain few mitochondria and derive most of their energy from glycolysis. The subcellular localisation and mechanism of this oxidase system have been the subject of considerable investigation and controversy. We describe here a cytochrome *b* system which becomes incorporated into the phagocytic vacuoles of human neutrophils. It is distinct from the cytochrome systems of the endoplasmic reticulum and mitochondria, and abnormalities in patients with CGD implicate it as an essential component of the microbicidal oxidase system.

Human neutrophils were purified by dextran sedimentation of erythrocytes, centrifugation through a gradient of Ficoll–sodium metrizoate and hypotonic lysis of residual erythrocytes. The effect of stimuli that initiate the metabolic burst on the visible light spectrum was examined in a split-beam spectrophotometer[4] after the addition to a suspension of purified neutrophils of latex particles opsonised with IgG or phorbol myristate acetate. This resulted in marked spectrophotometric changes which differed for the two stimuli. The latex particles produced a broad peak at about 416 nm with a shoulder at 442 nm and a minor peak at about 560 nm (Fig. 1). The 416-nm peak was reduced by the addition of KCN (2 mM) revealing the shoulder at 442 nm as a distinct peak at 449 nm. Phorbol myristate produced a peak at 456 nm with a secondary smaller peak at $\sim$430 nm.

The possibility that these spectroscopic changes could be related to phagocytic vacuoles was then examined as this is the site where the oxidase system unites with the engulfed microbe[5]. A diaphorase enzyme system in neutrophils has been located in the plasma membrane, which invaginates to form the walls of the phagocytic vacuole and has been shown to be abnormal in CGD[6]. Phagocytic vacuoles (Fig. 2) were isolated by flotation on sucrose gradients followed by differential centrifugation. The preparation contained latex particles, most of which were enclosed in bilamellar membranes. Granule contents could be clearly seen to have been released into some of the phagosomes. Concanavalin A binds to the surface of neutrophils[7] and a radiolabelled derivative was used as a plasma membrane marker at concentrations well below those that result in metabolic stimulation of the cell[7]. Ten per cent of the radioactive lectin became bound to the cells and 1·44% of the total activity in the homogenate was recovered with the phagosome preparation. This was found to be free of measurable contamination by endoplasmic reticulum as it contained less than 0·004% of the marker enzyme NADPH cytochrome *c* reductase[5] present in the homogenate, and lacked spectrophotometric evidence of cytochrome P450 (ref. 8). Complete lack of spectroscopic evidence of cytochrome oxidase indicated little mitochrondrial contamination[8].

Dithionite difference spectra of these vacuoles gave distinct peaks at 429 and 560 nm at room temperature, characteristic of a cytochrome *b* (ref. 8). These peaks were more clearly defined at slightly shorter wavelengths when examined at 77 K (Fig. 3).

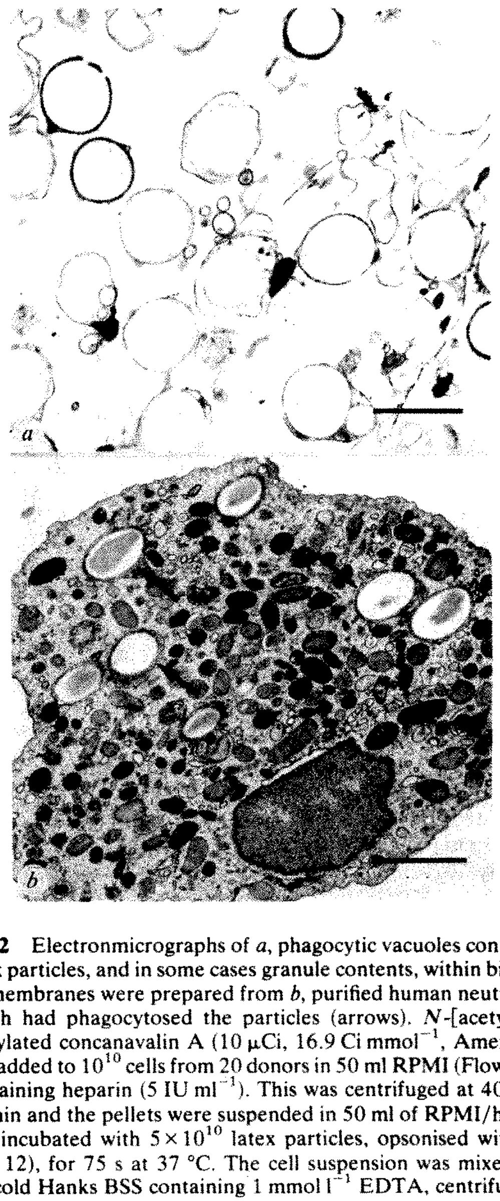

Fig. 2 Electronmicrographs of *a*, phagocytic vacuoles containing latex particles, and in some cases granule contents, within bilamellar membranes were prepared from *b*, purified human neutrophils which had phagocytosed the particles (arrows). *N*-[acetyl-^{3}H]-acetylated concanavalin A (10 μCi, 16.9 Ci mmol^{-1}, Amersham) was added to 10^{10} cells from 20 donors in 50 ml RPMI (Flow Labs) containing heparin (5 IU ml^{-1}). This was centrifuged at 400*g* for 10 min and the pellets were suspended in 50 ml of RPMI/heparin and incubated with 5×10^{10} latex particles, opsonised with IgG (ref. 12), for 75 s at 37 °C. The cell suspension was mixed with ice-cold Hanks BSS containing 1 mmol l^{-1} EDTA, centrifuged at 400*g* for 10 min, and the pellets were homogenised in 15 ml of 0.34 mol l^{-1} sucrose in a Douce homogeniser with 100 strokes of a B pestle. The homogenate was mixed with 30 ml of 50% sucrose and 15 ml of the mixture was placed in the bottom of a 60 ml Beckman centrifuge tube and overlaid with 30 ml of 23% and then 10 ml of 11.2% sucrose and centrifuged at 100,000*g* for 10 h at 4°C in a Beckman L2-65B centrifuge. The material at the interface between the 11.2% and 23% sucrose was aspirated, the sucrose concentration adjusted to 0.34 mol l^{-1} with H_2O containing 1 mM EDTA and 5 IU ml^{-1} heparin, and centrifuged at 27,000*g* for 15 min in a Sorvall SS-3 centrifuge. The pellets were resuspended in 0.34 mol l^{-1} sucrose which, like all the other sucrose solutions, contained 1 mmol^{-1} EDTA and 5 IU ml^{-1} heparin. Scale bars, 1 μm.

A carbon monoxide difference spectrum produced a small peak at 420 nm which could indicate binding of CO by the cytochrome *b*. Such a CO-bonding pigment may function as an oxidase (cytochrome o) of a type which has not been previously described in mammalian cells[8]. Dithionite difference spectra on

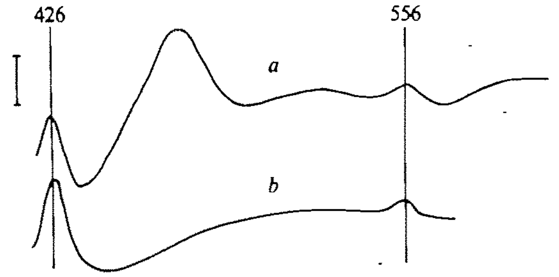

Fig. 3 Dithionite difference spectra at 77 K of a whole neutrophil homogenate (*a*) and a purified preparation of phagocytic vacuoles (*b*) (see legend to Fig. 2 for experimental details). Absorbance scale = 0.0056 and 0.0028 of full scale for *a* and *b* respectively.

the whole homogenate gave a similar pattern with, in addition, a peak at 475 nm and a minor broad peak between 510 and 540 nm. Similar difference spectra were observed in three separate homogenates each containing pooled cells from 20 normal subjects, and in 15 homogenates of cells from individuals. The 475-nm peak was identified as that of myeloperoxidase using purified human material[9] for which the dithionite difference spectra gave a classical peak at 475 nm which was shifted slightly to 462 nm by the addition of CO (Fig. 4). There were no obvious peaks at lower wavelengths. There was no spectroscopic evidence of myeloperoxidase in the phagocytic vacuole preparation (Fig. 3) which was calculated to contain ~2.4% of the cytochrome *b* in the whole homogenate by comparing the integrated areas under the 560-nm peaks.

These studies indicate the presence of a relatively pure cytochrome *b* in the phagocytic vacuoles which is distinct from both the P450 system in the endoplasmic reticulum and the mitochondrial cytochrome system. This cytochrome seems to be a likely component of the microbicidal oxidase system and its spectrum was thus examined in neutrophil homogenates from patients with CGD. This condition is characterised by defective activity of this oxidase system[3] and impaired killing of certain bacteria, leading to recurrent pyogenic infections which are often fatal. The characteristic spectrum of cytochrome *b* was missing or grossly abnormal in cell homogenates in all six of the patients that we have studied[10]. Half the normal level of this cytochrome was found in the two, clinically unaffected, maternal obligate heterozygote carriers[10] of this sex-linked disease[11], indicating that the spectral changes observed in the patients were not simply a consequence of ill health.

Fig. 4 Dithionite and CO difference spectra of an homogenate of neutrophils from a pool of 20 normal donors and of purified human myeloperoxidase. Neutrophils were purified and homogenised in 0.34 mol l^{-1} sucrose as described in Fig. 2, and 4 mg of protein was added to each cuvette. Absorbance scale = 0 0056 of full scale.

24, 25-Dihydroxyvitamin D is a metabolite of vitamin D essential for bone formation

THE question whether vitamin D acts directly at sites of bone formation or indirectly at sites of calcium and phosphate absorption has long been a source of argument, with no general conclusion reached. Treatment of rachitic chicks with 1-hydroxyvitamin D_3, the synthetic analogue of 1,25-dihydroxyvitamin D_3, does not prevent most of the changes seen in bone affected by rickets, in spite of normal plasma levels of calcium and inorganic phosphate (unpublished). Similar findings have been reported for man[1], suggesting that vitamin D affects bone formation directly and that the effect is mediated by a metabolite(s) other than 1,25-dihydroxyvitamin D_3. In normocalcaemic animals, the predominant dihydroxylated metabolite of vitamin D in the blood is 24, 25-dihydroxyvitamin D and, like 1,25-dihydroxyvitamin D, it is synthesised in the kidney[2,3]; but nothing is known of its function. Improved calcium retention has been reported in anephric patients treated with 24,25-dihydroxyvitamin D_3 (ref. 4), which has been observed to accumulate preferentially in fetal bones of rat[5] and in callus tissue formed after experimental fracture (unpublished). We now

Table 1 Body weight and plasma concentration of calcium and inorganic phosphate of chicks treated with vitamin D derivatives

Treatment	Body weight (g)	Plasma Ca (mg per 100 ml)	Plasma Pi (mg per 100 ml)
Vitamin D_3	264.2±5.3	10.9±0 40	6.8±0 22
24,25-Dihydroxyvitamin D_3	266.7±9.2	9 4±0.45	6.3±0 17

Table 2 Comparison of tibial epiphyses, metaphyses and diaphyses in the different groups

24,25-Dihydroxyvitamin D_3	1-Hydroxyvitamin D_3 + 24,25-dihydroxyvitamin D_3	None ($-D_3$)	Vitamin D_3	Treatment
3.3±0.3	3.4±0.3	5.0±0.4	3.5±0.2	Width of cartilage in epiphyses (mm)
25±4	26±4	35±8	28±6	Width of metaphyseal bone trabeculae (μm)
9±2	5±1	16±3	6±1	No. of osteoclasts per mm in the metaphysis
+	+	++	±	Hypertrophied osteocytes in the diaphysis
±	±	+++	±	Connective and preosteogenic tissue between trabeculae in metaphysis
+++	++	+	++	Haemopoietic bone marrow in metaphysis

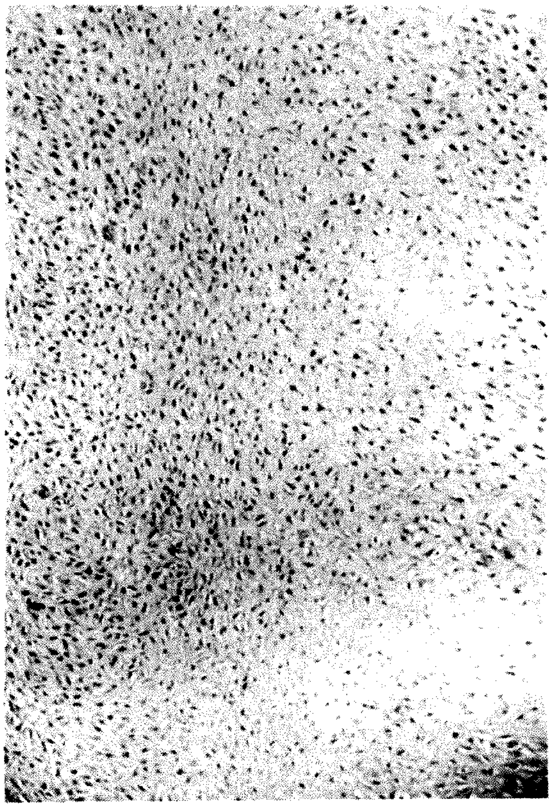
Measurements were made by projecting the haematoxylin and eosin stained para-sagittal longitudinal sections of tibiae on a microscope screen. The width of the epiphyses was measured ×40 and that of metaphyseal trabecule ×400. Metaphyseal osteoclasts were counted for areas 0.5×0.5 mm (×400) and calculated per mm^2 as described before[8]. The figures are mean values±s.e.m. of 5–10 measurements from each chick, six chicks in each group.

report that when rachitic chicks are exposed to various therapeutic treatments with metabolites of vitamin D, the presence of 24,25-dihydroxyvitamin D is essential for the healing process.

One-day-old male chicks (*Gallus domesticus*) were depleted of vitamin D by feeding them a vitamin-D-deficient diet[6] for 4 weeks. They were then divided into four groups and injected subcutaneously daily with, respectively, vitamin D_3; 24,25-dihydroxyvitamin D_3; 24,25-dihydroxyvitamin D_3 and 1-hydroxyvitamin D_3, or nothing but propylene glycol. After 11 d the chicks were weighed and killed, and plasma was prepared for the estimation of calcium and inorganic phosphate as before[7](Table 1). Proximal tibiae were removed, fixed in formalin, decalcified in formic acid and embedded in paraffin. Longitudinal 6–7-μm sections were stained with haematoxylin and eosin or with toluidine blue and examined by light microscopy. The length of the cartilaginous epiphyses, the width of the metaphyseal trabeculae and the number of metaphyseal osteoclasts were compared between groups. Other important morphological findings were graded from ± to +++ (Table 2).

As Table 1 shows, the vitamin-D-deficient chicks, compared with the vitamin-D_3-treated chicks, showed hypocalcaemia ($P<0.01$) and hypophosphataemia ($P<0.01$) associated with growth retardation ($P<0.05$). 24,25 Dihydroxyvitamin-D_3-treated birds grew as well as those treated with vitamin-D_3, but were unable to maintain normal plasma levels of calcium ($P<0.05$). Only birds treated with both 24,25-dihydroxyvitamin D_3 and 1-hydroxyvitamin D_3 maintained normal plasma levels of both calcium and inorganic phosphate, and their growth was apparently better than that of vitamin-D_3-treated birds ($P<0.05$).

Fig. 1 Tibial epiphysis from a vitamin-D-depleted chick. Note typical rickets; there is a wide zone of abnormally orientated chondrocytes between the proliferating zone and the zone of provisional calcification. (Haematoxylin and eosin×120.)



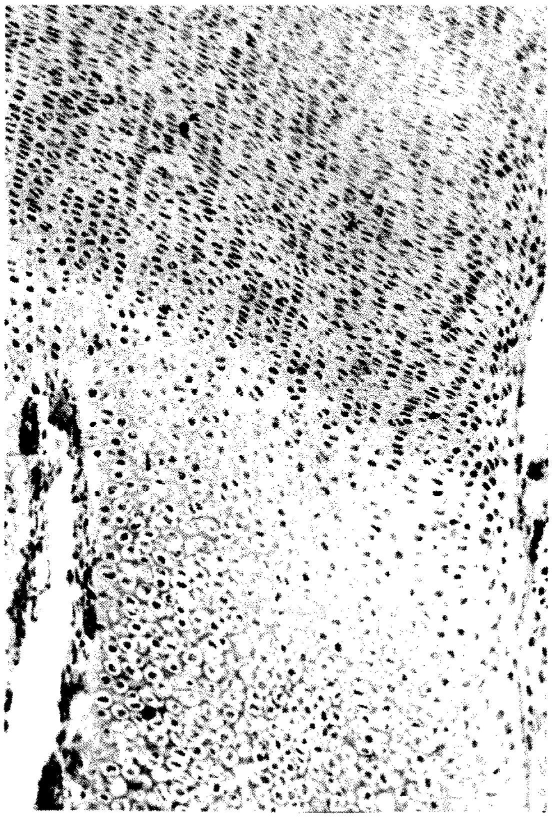


Fig. 2 Tibial epiphysis from a chick treated with 24,25-dihydroxyvitamin D_3 and 1-hydroxyvitamin D_3. Note normal arrangement of the proliferating, maturing and hypertrophic zones. (Haematoxylin and eosin×120.)

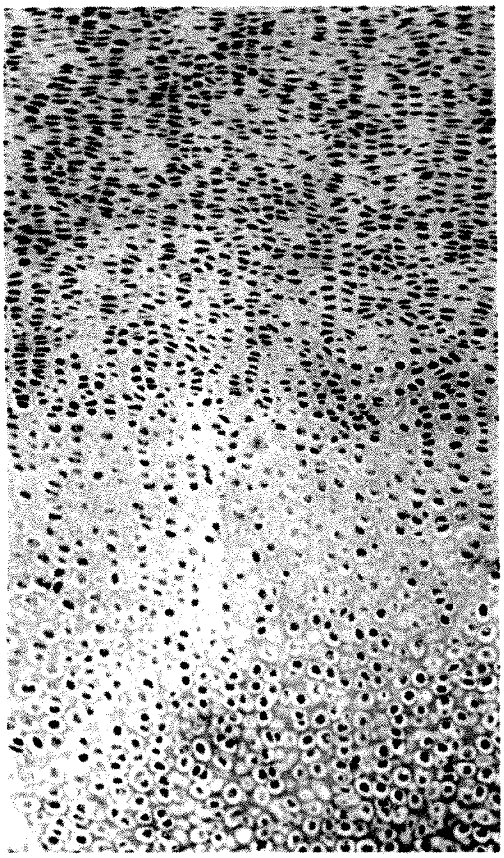
The tibial epiphyses in all birds were still cartilaginous. In the controls (vitamin-D_3-treated birds) the different zones of the epiphyses, which were 3.5±0.2 mm long (Table 2) were well defined. There was a straight demarcation line between the proliferating, maturing and hypertrophic zones. Metaphyseal trabeculae were parallel to the long axis of the tibiae. There were only a few osteoclasts (Table 2).

In the vitamin-D-deficient chicks the tibial epiphyses were longer—5.0±0.4 mm (Table 2). The zone of maturation was wide and disorganised, and the demarcation line between the zones of maturation and of hypertrophy was poorly defined (Fig. 1). In the metaphysis these were cartilaginous bars surrounded by osteoid, and numerous osteoclasts were found around the metaphyseal trabeculae (Table 2). The spaces between metaphyseal trabeculae were filled with a large amount of connective and preosteogenic tissue. In the diaphysis these were many hypertrophied osteocytes in wide lacunae.

Treatment with 1-hydroxyvitamin D_3 together with 24,25-dihydroxyvitamin D_3 completely cured the rickets, and the bones were indistinguishable from the control (Fig. 2, Table 2). Treatment with 24,25-dihydroxyvitamin D_3 also prevented rachitic bone lesions. Epiphyses were of the same length and morphology as in vitamin-D_3-treated chicks (Table 2, Fig. 3). In the metaphysis, however, there were fewer trabeculae compared to controls, but the diaphysis appeared normal in width. Abundant haemopoietic tissue was found between the metaphyseal trabeculae, and the number of metaphyseal osteoclasts was slightly greater (Table 2). Osteocytic hypertrophy was also seen in some diaphyseal trabeculae (Fig. 4). These findings, not characteristic of rickets, seemed to be a reflection of the lower plasma calcium levels.

Our study shows that in young growing chicks a combined treatment of the two renal dihydroxylated metabolites of vitamin D can prevent the bone changes seen in rickets, and that the bones formed in such birds are indistinguishable from those formed in birds treated with vitamin D_3. 24,25-Dihydroxyvitamin D_3 alone seems to be sufficient to prevent rachitic bone lesions, at least those affecting cartilage, but probably because of low levels of plasma calcium in our chicks, we saw some changes in the treated bones (fewer metaphyseal trabeculae than normal, together with osteocytic hypertrophy). Based on these findings and the observation that treatment with 1-hydroxyvitamin D_3 as the only source of vitamin D in chicks cannot prevent rachitic changes in bones in spite of normal levels of plasma calcium and inorganic phosphate (unpublished), we propose a function for 1,25-dihydroxyvitamin D and for 24,25-dihydroxyvitamin D_3; we suggest that 1,25-dihydroxyvitamin D_3 increases the calcium and phosphate levels of the extracellular fluid to a supersaturated state in which conditions, in the presence of 24,25-dihydroxyvitamin D_3 which probably acts directly on bone, mineralisation of bone matrix will occur. The possibility that the beneficial effect of 24,25-dihydroxyvitamin D_3 in the presence of 1-hydroxyvitamin D_3, is due to the formation of 1,24,25-trihydroxyvitamin D_3 was ruled out, as it was found that in similar conditions, using tritiated 24,25-hydroxyvitamin D_3, 1,24,25-trihydroxyvitamin D_3 could not be detected in intestine kidney or bone. The exact role that 24,25-dihydroxyvitamin D_3 plays in this process remains to be established.

Fig. 3 Tibial epiphysis from a chick treated with 24,25-dihydroxyvitamin D_3. Note normal arrangement of proliferating, maturing and hypertrophic zones. (Haematoxylin and eosin × 120.)



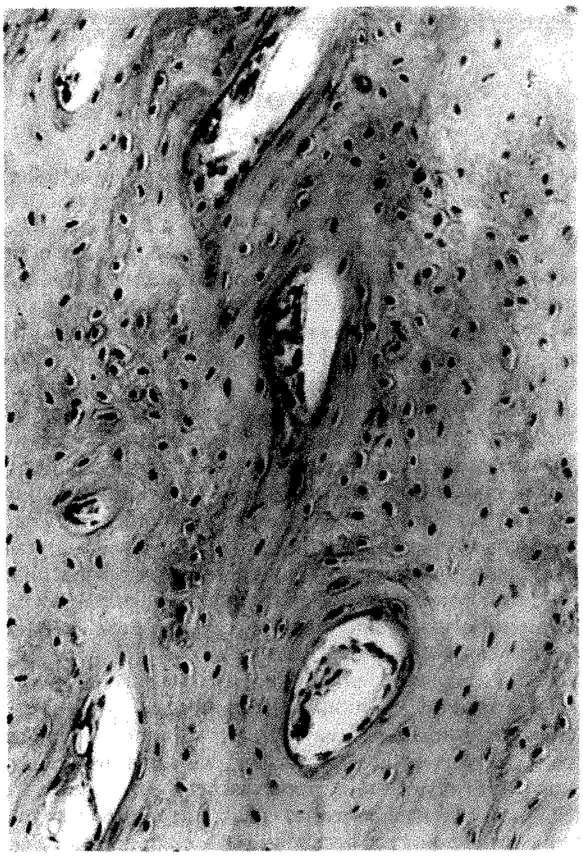


Fig. 4 Tibial diaphyseal trabecula to show slight osteocytic hypertrophy. This chick was treated with 24,25-dihydroxyvitamin D_3. (Haematoxylin and eosin × 250.)

We thank Professor Y. Mazur for 1-hydroxyvitamin D_3, and Drs U. Gloor and F. Weber, Hoffmann La Roche, for 24R,25-dihydroxyvitamin D_3. We thank M. Wolf for technical assistance. This work was supported in part by a grant to S.E. from the Chief Scientist Office, Israel Ministry of Health.

Ectopic dendritic growth in mature pyramidal neurones in human ganglioside storage disease

PYRAMIDAL CELLS are highly differentiated cortical neurones whose morphophysiological properties derive largely from dendritic systems that provide most of the postsynaptic sites for excitatory and inhibitory synaptic inputs[1]. As pyramidal cell function is closely linked to dendritic geometry[2,3] factors influencing dendritic growth determine to a large extent connectivity patterns in cortical neuronal organisations[4-6]. Although various experimental manipulations hinder attainment of normal dendritic geometry[7] no factors or conditions are known to induce dendritic growth and differentiation in intact, mature cortical neurones. I present here morphological evidence that in human ganglioside storage disease pyramidal neurones, having completed an initial period of normal dendritic growth, undergo a second phase of dendritic growth and differentiation at aberrant sites. I have referred to this in another context as ectopic dendrogenesis[8].

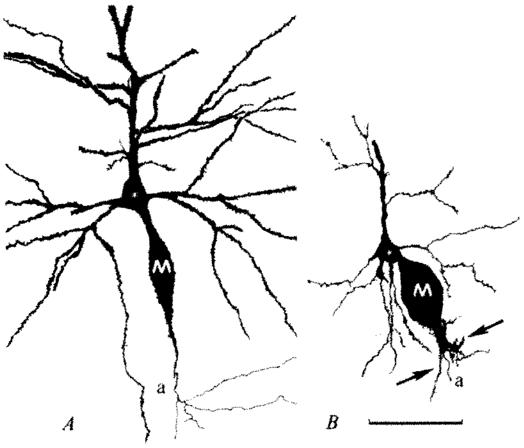

Fig. 1 Changes in abnormal growth characteristics of cortical pyramidal neurones in human ganglioside storage disease, G_{M2}-gangliosidosis (AB variant). Camera lucida drawings of Golgi preparations. *A*, Early stage; onset of seizures and developmental retardation. Neurone as seen in brain biopsy tissue. Reproduced by permission[9]. Dendrites truncated for purposes of illustration. Scale bar 75 μm. *B*, Terminal stage neurobehavioural deterioration, 30 months after observations in (*A*), postmortem tissue. Compare relative size of cell bodies (asterisks) and meganeurites (M) at the two stages. Atrophy of the normal dendritic system and robust growth of aberrant dendrites from the meganeurite (at arrows) occur late in the gangliosidosis. a, Axon. (*A*) is reproduced from ref. 9.

Observations were made initially on cortical pyramidal neurones from a 14-month-old child who presented with seizures and mild neurobehavioural retardation[9]. The diagnosis of G_{M2}-gangliosidosis, AB variant, was established by biochemical analysis of brain biopsy tissue[10]. Golgi studies at the time of the diagnostic biopsy revealed two features of pyramidal neurone morphology. These features are apparent in Fig. 1*A*; Fig. 1*B* shows postmortem findings. The neurone in Fig. 1*A* has well developed and normal appearing dendritic systems as judged by other developmental data on neurones of immature human cerebral cortex[11]. The most significant finding reported originally was the presence of large, fusiform spine-bearing structures, meganeurites (M in Fig. 1*A*) interposed between the cell body and initial portion of the axon. Meganeurites have

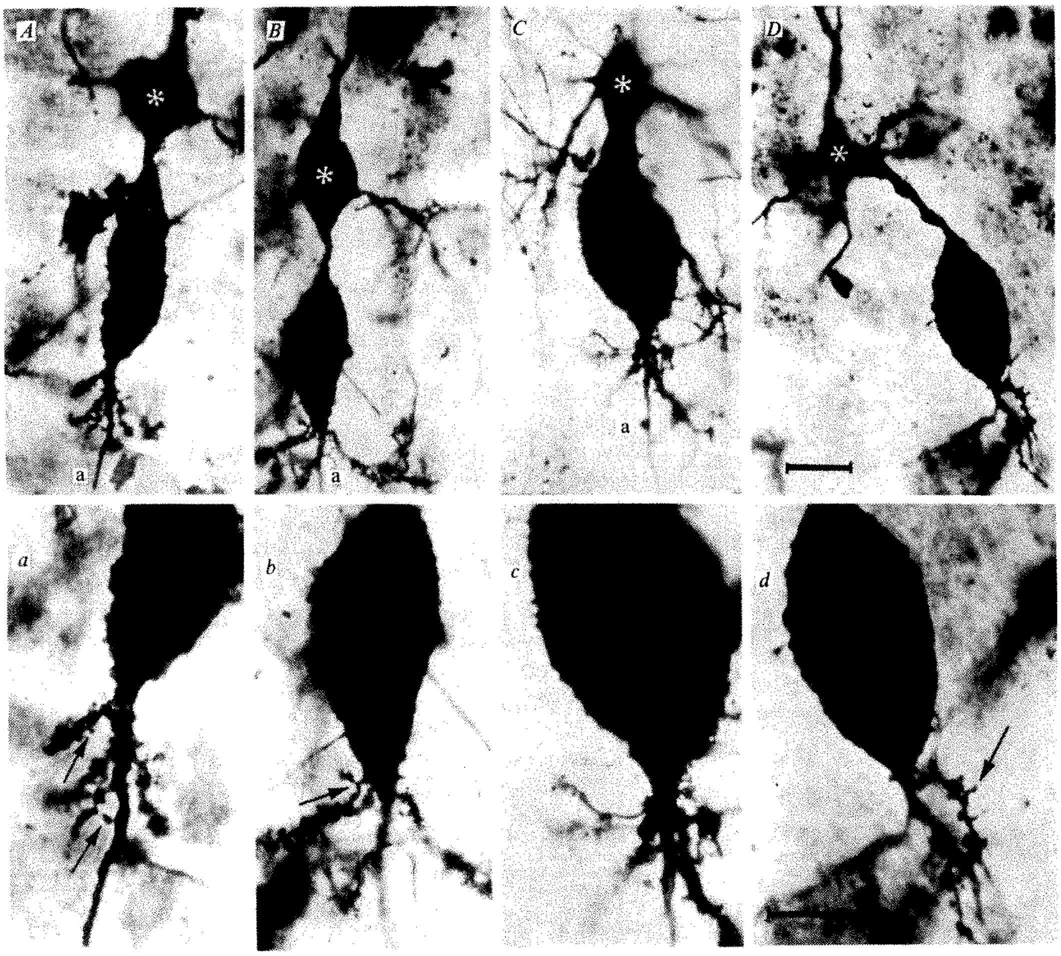

Fig. 2 *A–D*, Examples of medium sized pyramidal neurones at the terminal stage of G_{M2}-gangliosidosis (AB variant) in a 44-month-old child. Golgi preparations of postmortem brain tissue. Cell bodies (asterisks) give rise to variable processes that become massive fusiform or oval structures, meganeurites. Most meganeurites are covered with spines, shown more clearly at higher magnification (*a–d*). Dendrites with dendritic spines (at arrows in *a*, *b* and *d*) arise from the meganeurites. a, Axon. Scale bars, 20 μm.

0028–0836/78/0276—0520$01.00

since been found in several human ganglioside storage disorders[9] and in feline G_{M1}-gangliosidosis[12].

Between initial diagnosis and death, 30 months later, the child's clinical condition deteriorated in a manner similar to that seen in classical Tay-Sachs disease. Examination of Golgi preparations of postmortem brain tissue (Fig. 1*B*) showed striking changes in pyramidal cells from the first observations 30 months earlier (Fig. 1*A*). Extraordinary growth of meganeurites and atrophy of perisomatic dendritic systems are evident as described in classical Tay-Sachs disease[9]. A significant finding is the outgrowth from the meganeurite of robust dendrites bristling with dendritic spines (Fig. 1*B*, at arrows). Further examples of small and medium pyramidal neurones with prominent dendrites arising from meganeurites are shown in Fig. 2. Several meganeurite-related dendrites in Fig. 2(*a–d*) exhibit a variety of spine shapes characteristic of normal dendritic systems of mature pyramidal neurones[13].

Golgi impregnations of cortical pyramidal neurones of postmortem tissue establish that the aberrant structures designated meganeurites give rise to large spine-covered processes that are identical in every respect to spiny dendrites. Since at an early stage in the course of the ganglioside storage disease studied here meganeurites are prominent but devoid of neurites or dendrites, it follows that growth of meganeurite related dendrites occurred after the period of initial normal dendritic development. The finding that meganeurites serve as 'pseudosomas' for the new dendritic systems confirms previous indications that meganeurites continue to exhibit embryonic growth characteristics that are not expressed by the rest of the ganglioside-laden neurone[9,12,14]. The mechanism by which abnormal ganglioside metabolism signals the genetic machinery of the neurone to synthesise spine-rich dendritic-like membrane for incorporation into meganeurites and related dendrites is unknown. The unprecedented findings here of aberrant dendritic growth induction in otherwise mature human cortical pyramidal neurones suggests that the pursuit of factors associated with abnormal ganglioside metabolism will shed light on the developmental mechanisms of neurone shape regulation and dendritic membrane distribution.

I thank Drs I. Rapin, L. Schneck and K. Suzuki for their cooperation, M. Buschke and S. Brown for technical assistance, and the NIH for support.

α- And β-adrenoreceptor blockers have opposite effects on energy metabolism of the central auditory system

THE autoradiographic ^{14}C-deoxyglucose assay has made it possible to measure the local rates of glucose utilisation (LCGU) simultaneously in all the macroscopic components of the central nervous system[1]. Because of the close relationship between local cerebral functional and metabolic activities, the method has proved useful in mapping the distribution of alterations in cerebral functional activity in experimental physiological states[2], and to identify components of cerebral dopaminergic systems in studies with the dopamine agonists, apomorphine[3] and amphetamine[4]. Noradrenergic systems, including both α- and β-adrenergic receptors, have been identified in brain and implicated in various behavioural and affective states in man and animals[5,6]. Drugs with α- or β-adrenergic blocking actions exhibit effects on mood and behaviour[5,6]. Propranolol, a β-adrenergic blocking agent, has, in fact, been used as a therapeutic agent in the control of psychotic symptoms[7,8]. In an attempt to localise the regions of the brain in which functional and/or metabolic activities are altered by adrenergic blockade, we have used the ^{14}C-deoxyglucose method to study the effects of the β-adrenergic blocker, DL-propranolol, and the α-adrenergic blocker, phentolamine. The results demonstrate strikingly opposite effects of these drugs in the auditory system of the rat.

Normal male Sprague-Dawley rats (350–400 g) were catheterised through the femoral artery and vein under halothane anaesthesia. A loose-fitting abdominal-pelvic plaster cast was applied to the animal for restraint, and the animal was allowed to recover from the effects of anaesthesia for at least 2 h. The drugs were then administered by continuous intravenous infusion. Controls were infused with normal saline at 0.04 ml per min; drug-treated animals received equivalent amounts of saline containing either DL-propranolol-HCl or phentolamine mesylate. Propranolol concentration in the saline infusion medium was adjusted to provide a rate of infusion of 0.25, 0.5 or 1.0 mg of drug per kg body weight per min; the concentration of phentolamine was adjusted to 0.25, 0.5 or 0.85 mg per kg per min. The infusions were maintained for 40 min before administration of ^{14}C-deoxyglucose and continued during the subsequent 45 min required for measurement of local cerebral glucose utilisation. The period of measurement of cerebral glucose utilisation was initiated by administration of an intravenous pulse of 125 μCi 2-deoxy-D-[1-^{14}C]glucose (50–55 mCi mmol^{-1}) per kg body weight. Timed arterial blood samples were then drawn at predetermined intervals during the next 45 min (ref. 1). The blood samples were immediately centrifuged, and the plasma was separated and assayed for ^{14}C-deoxyglucose and glucose concentrations as previously described[1]. Approximately 45 min after the pulse the animal was decapitated, and the brain was removed, frozen in Freon XII at −60 to −70 °C for sectioning and autoradiography[1]. Local tissue concentrations of ^{14}C were determined by densitometric analysis of the autoradiograms[1]. Local cerebral glucose utilisation was calculated from the time courses of the plasma ^{14}C-deoxyglucose and glucose concentrations and the local tissue concentrations of ^{14}C by means of the operational equation of the ^{14}C-deoxyglucose technique[1].

Administration of propranolol was associated with changes in several systemic physiological variables. Pulse rate declined; body temperature tended to fall by as much as 2 °C; and arterial P_{CO_2} and P_{O_2} tended to rise. During the administration of the propranolol all the animals showed a gradual decrease in alertness and responsiveness to tactile and auditory stimulation. Propranolol also produced dose-dependent decreases in local cerebral glucose utilisation. With increasing dosage more and more cerebral structures exhibited statistically significant

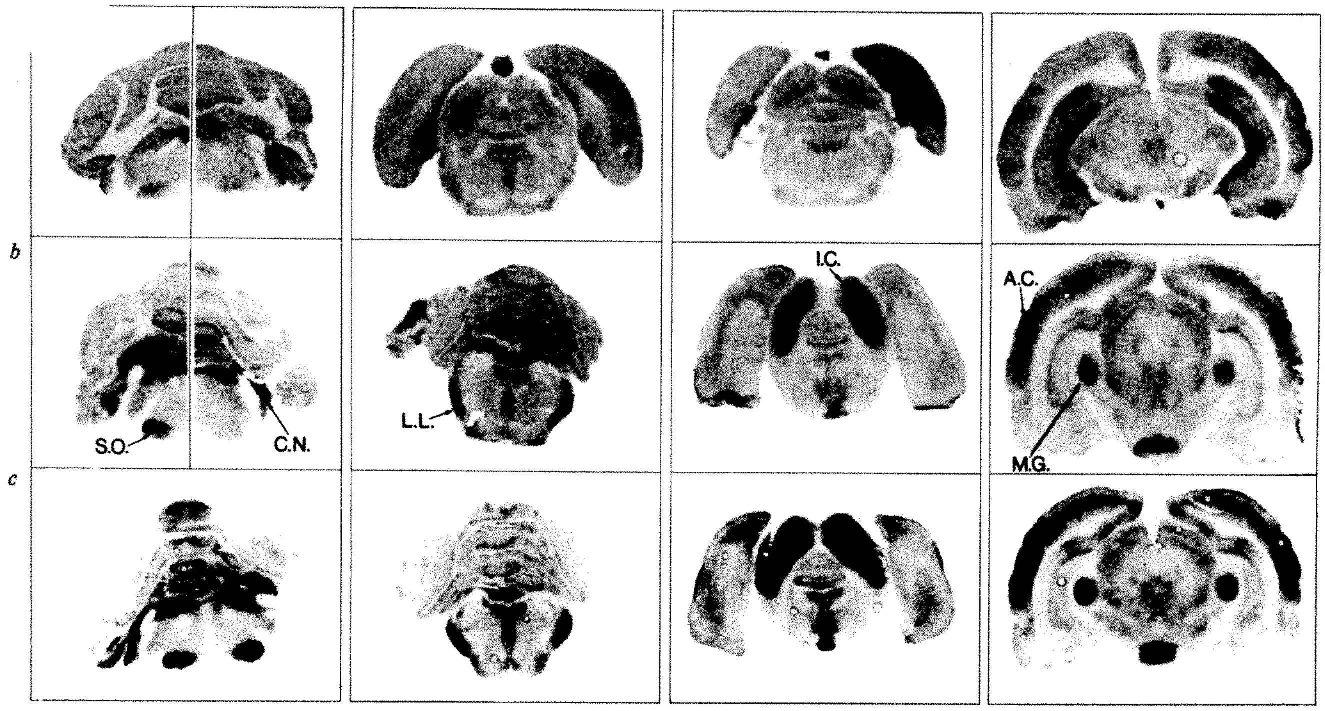

Fig. 1 Autoradiographs of brain sections from three rats illustrating effects of propranolol and phentolamine on glucose utilisation of the auditory system. The sections were at levels that include all components of the auditory system. *a*, Sections from rat given DL-propranolol-HCl 1 mg per kg per min. *b*, Sections from control rat given normal saline. *c*, Sections from rat administered phentolamine mesylate 0.85 mg per kg per min. reductions in glucose utilisation and to a greater degree. At the highest dosage (1 mg per kg per min) glucose utilisation was significantly depressed in all but 2 of the 26 structures examined (Table 1). Although the magnitude of the effects was substantial in many structures, the greatest depressions were in all the components of the auditory system, (cochlear nucleus, superior olive, nuclei of lateral lemniscus, inferior colliculus, medial geniculate body, and auditory cortex, Table 1). Normally, these structures have relatively high rates of glucose utilisation in the brain and, therefore, clearly stand out in the autoradiographs as areas of high optical density (Fig. 1*b*). Propranolol reduced the rates of metabolism of the auditory structures more than those of other structures which caused their representation in the autoradiographs to fade into the background of the other structures (Fig. 1*a*).

The α-adrenergic blocker phentolamine also produced systemic physiological effects. Body temperature tended to fall by as much as 3 °C, and blood pressure and pulse rate fell significantly with all doses used. Most of the animals exhibited progressive decreases in alertness and remained quiet with the eyes closed, but they responded to tactile and auditory stimuli. The penetrability of phentolamine through the blood–brain barrier has been reported to be limited[9], but, nevertheless, the drug at the concentrations used did exert effects on the glucose utilisation of several structures of the brain. Metabolic rate tended to be reduced in most of the structures examined, but these effects were of lesser magnitude than those seen with propranolol. The most striking effects, however, were also in the components of the auditory system, but in contrast to the effects of propranolol, glucose utilisation in these structures was stimulated by phentolamine (Table 1). The effects on the auditory system were sufficiently pronounced that they could readily be visualised in the autoradiograms by the markedly increased densities in the regions corresponding to these structures (Fig. 1*c*).

The results of these studies demonstrate that the α- and β-adrenergic blocking agents, phentolamine and propranolol, respectively, have striking and opposite effects on glucose utilisation in the auditory system. These effects on energy metabolism seem to reflect alterations in functional activity. Furlow *et al.*[10] found that doses of propranolol and phentolamine like those used in the present studies produce corresponding effects on auditory evoked responses in the rat; propranolol depresses and phentolamine enhances the amplitude of all components of the evoked auditory responses.

The stimulation of glucose utilisation by phentolamine seems to be dependent on the presence of auditory input. In rats deafened bilaterally by rupture of the tympanic membranes and occlusion of the external auditory canals with wax, phentolamine failed to increase glucose utilisation in the auditory structures significantly above the low levels seen in deafened animals. These results indicate that the effect of phentolamine is manifested only during auditory input and suggest that its effects in the auditory system may be the result of blockade of an α-adrenergic negative feedback pathway in the central auditory system. α-Adrenergic mechanisms have previously been implicated in the auditory system, and noradrenaline-containing nerve terminals have been localised in most of the structural components of the auditory system[11–16].

DL-Propranolol is not only a β-adrenergic blocking agent, but it also has membrane-stabilising properties. Experiments with sotalol, a more specific β-adrenergic blocking agent lacking membrane-stabilising properties[17], indicate that it does not affect LCGU of the auditory system like DL-propranolol, but it also failed to produce the same behavioural effects, possibly because of its limited ability to cross the blood–brain barrier[17,18]. L-Alprenolol, another specific β-adrenergic blocker, has effects similar to those seen with propranolol, but this drug also has the membrane-stabilising property. Preliminary studies with the separated isomers of propranolol indicate that they have almost equal effects on the glucose utilisation of the auditory system, despite the fact that L-propranolol is twice as potent a β-adrenergic blocking agent as the D-isomer in the central nervous system[19]. Both, however, are approximately equally potent in membrane stabilisation[20], and these results suggest that the membrane-stabilising properties might be responsible for the effects in the auditory system.

Propranolol has recently been proposed as a therapeutic agent for treatment of psychoses[7,8] and is particularly effective in suppressing the auditory hallucinations in schizophrenia[7,21]. Atsmon *et al.*[22] have reported a case study in which the administration of an α-adrenergic blocking agent reversed the beneficial effects of propranolol in a psychotic patient. The effects of propranolol on the auditory system observed in the present studies might be related to its effects in the control of auditory hallucinations.

High-affinity enkephalin-degrading peptidase in brain is increased after morphine

CONSIDERABLE evidence now exists to suggest that the endogenous opioid pentapeptides Met-enkephalin (Tyr-Gly-Gly-Phe-Met) and Leu-enkephalin (Tyr-Gly-Gly-Phe-Leu) function as neurotransmitters in the central nervous system. A correlate of this hypothesis is that a specific inactivation mechanism must operate in the vicinity of opiate receptors to turn off rapidly the enkephalin signal. Indeed recent studies have shown that the pentapeptides are subject to extremely rapid inactivation in various tissues, occurring primarily by cleavage of the Tyr–Gly amide bond[1–5]. This feature accounts for the short-lasting biological activity of these peptides, contrasting with the potent activity of synthetic analogues such as (D-Ala^2)-Met-enkephalinamide in which this bond is protected[6]. However, many tissues including brain contain a spectrum of peptidases with low specificities and affinities[7] and no evidence has been yet provided for the involvement of a specific

0028-0836/78/0276—0523$01.00

enzyme in the regulation of enkephalinergic transmission. We now report the presence of a high-affinity peptidase in a particulate fraction of mouse striatum splitting the Leu-enkephalin molecule with release of a tripeptide fragment (Tyr-Gly-Gly) and exhibiting definite substrate specificity. The marked and selective increase in the activity of this peptidase in the striatum of mice chronically treated with morphine suggests that it might be associated with enkephalinergic transmission.

Enkephalin-hydrolysing activity exhibits a considerable heterogeneity in rat brain subfractions[8]. Starting from the hypothesis that a specific peptidase involved in the control of enkephalin concentration in the synaptic cleft should be membrane-bound and should exhibit a high affinity for the pentapeptides, we have compared the saturation kinetics of Leu-enkephalin-hydrolysing enzymes in a soluble and a particulate fraction from mouse striatum, a region containing a high concentration of enkephalins and opiate receptors. As shown in Fig. 1 the shape of the curves representing the fraction of ^{3}H-Leu-enkephalin hydrolysed as a function of total substrate concentration is monophasic in the soluble fraction but clearly biphasic in the particulate fraction. In the particulate, at least two classes of enkephalin-hydrolysing activities are present; one seems to correspond to that found in the soluble fraction ($IC_{50} \sim$ 30 µM in both cases), whereas the other, representing 20–25% of the total hydrolysing activity at low enkephalin concentrations, is restricted to the particulate fraction. This component, represented in Lineweaver–Burk plots (Fig. 1*b*) exhibits a high affinity ($K_m = 90$ nM) as compared to most peptidases for which the K_m is in the range 10–100 µM (ref. 9).

Table 1 Inhibitory potencies of various compounds on the hydrolysis of ^{3}H-Leu-enkephalin by particulate and soluble fractions of mouse striatum

	IC_{50} (nM) for ^{3}H-Leu-enkephalin hydrolysis by Particulate fraction		Soluble fraction

Particulate and soluble fractions from mouse striata were prepared as described in Fig. 1. Incubations (20°C, 15 min) in the presence of 20 nM ^{3}H-Leu-enkephalin and increasing concentrations (6–8) of the various compounds. ^{3}H-Leu-enkephalin hydrolysis evaluated by column chromatography on Porapak Q beads (see Fig. 1). IC_{50} values were determined by iterative analysis of the concentration-inhibition curves, analogous to that reported in Fig. 1, by a computer program based on the least squares (variance-covariance matrix)[13]. This analysis provided an accurate determination of IC_{50} for the inhibition of the two peptidasic activities in the particulate fraction in the case of a clear biphasic curve, that is, when the IC_{50} differed by more than 50-fold. This was not the case for several compounds: (D-Phe^4)Met-enkephalin, (D-Ala^3) Met-enkephalin, bradykinin and substance P, for which a clear plateau was not present and therefore the IC_{50} on the high-affinity peptidase could not be estimated with accuracy.

* Maximal inhibition ~70%.

† Maximal inhibition ~90%.

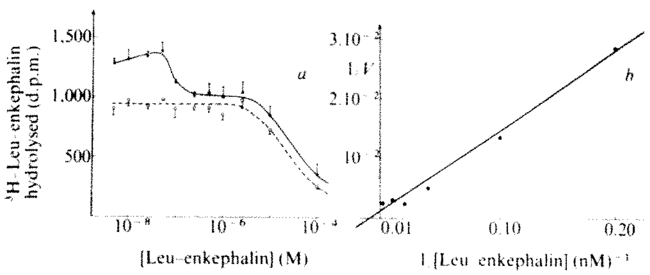

Fig. 1 ^{3}H-Leu-enkephalin hydrolysed by particulate and soluble fractions from mouse striatum incubated in the presence of increasing concentrations of non-radioactive Leu-enkephalin. Striata of three male Swiss mice (18–20 g) were homogenised into 10 ml of 0.05 M Tris-HCl buffer *p*H 7.4 (3 × 5 s at 1,500 r.p.m. in a glass–Teflon Potter homogeniser, clearance 0.1–0.15 mm). A pellet was obtained after two successive centrifugations at 4°C (1,000 *g* × 1 min and 200,000*g* × 1 min) and the supernatant of the second centrifugation was kept as 'soluble fraction'. The pellet was resuspended using a Dounce homogeniser (clearance 20–55 µm) into 10 ml of cold buffer and centrifuged (200,000*g* × 1 min). The resulting pellet, after a wash without resuspension with 15 ml of buffer (which was then discarded), was resuspended into 5 ml of buffer: this suspension was used as 'particulate fraction'. After a 15-min preincubation at 20°C, incubations (15 min, 20°C) of the particulate or soluble fractions were started by addition of 100 µl of buffer containing ^{3}H-Leu-enkephalin (1 nM final concentration; the Radiochemical Centre, 41Ci mmol^{-1}, previously purified by chromatography on Porapak beads microcolumns) and stopped by the addition of 50 µl 0.1 M HCl followed by heat deproteinisation (95°C, 15 min). ^{3}H-metabolites were separated from intact ^{3}H-Leu-enkephalin by chromatography[5] on 80 mg Porapak Q (100-120 mesh, Waters Assoc.) contained in Pasteur pipettes. The metabolites were eluted from column with 2 × 1 ml distilled water directly collected into scintillation vials; Leu-enkephalin was retained on the column. *a*, Effects of increasing concentrations of non-radioactive Leu-enkephalin on the formation of hydrolysis ^{3}H-products by the particulate fraction (●) or the soluble fraction (○). *b*, Lineweaver–Burk plot of the high-affinity Leu-enkephalin hydrolysing activity (corresponding to substrate concentration below 5 µM, that is, up to the plateau) of the particulate fraction (same data as in *a*). The rate of hydrolysis (fmol per mg protein per min) was evaluated, taking into account the specific activities of the substrate. $K_m = 90$ nM, $V_{max} = 850$ fmol per mg protein per min. Means ±s.e.m. of three determinations.

In six independent experiments the presence of this high-affinity component was confirmed and the analysis of the data by a computer program (see Table 1 legend) led to mean K_m values (±s.e.m.) of 41 ± 10 nM and of 55,000 ± 17,000 nM for the high- and low-affinity peptidase activities, respectively. Both peptidase activities in the particulate fraction vary linearly as a function of protein concentration or time.

The high-affinity of a class of peptidase activity found in the particulate fraction suggested that it might exhibit substrate specificity. This was indirectly investigated by determining the inhibitory potency of a variety of compounds towards the different classes of peptidase activities (Table 1). The specificity of the high-affinity peptidase activity is demonstrated by the enormous range in inhibitory potency of the various compounds tested (IC_{50} between 10 and >100,000 nM). Although the low-affinity peptidase activities in both particulate and soluble fractions also exhibit some specificity, the range in IC_{50} variation is much less pronounced. The main conclusions which can be drawn from the data of Table 1 can be summarised as follows:

(1) Stereochemical requirements are more stringent in the case of the high-affinity peptidase as evidenced for the pair of (Ala^3)-Met-enkephalin stereoisomers.

(2) The integrity of the enkephalin molecule is important for the inhibitory potency as shown by the dramatic loss of activity towards all classes of peptidases in the fragments Tyr, Tyr-Gly, Tyr-Gly-Gly and Tyr-Gly-Gly-Phe.

(3) The C-terminal moiety of the enkephalin molecule seems to be more important for inhibition of the high-affinity peptidase

Table 2 Identification by thin-layer chromatography of the radioactive compounds present after incubation of ^{3}H-Leu-enkephalin with a particulate fraction of mouse striatum

	+Gly-Gly-Phe-Met (10 μM)	303 ± 43	118 ± 30***	16,503 ± 518	575 ± 65	265 ± 83*
(2)	Control	838 ± 110	530 ± 33	16,305 ± 478	998 ± 45	955 ± 65
	+Gly-Gly-Phe-Met (10 μM)	743 ± 15	100 ± 10***	17,545 ± 555	895 ± 15	293 ± 18***
(3)	Control				570 ± 50	660 ± 53
	+Gly-Gly-Phe-Met (10 μM)				555 ± 88	215 ± 18***

Incubation of samples (30 μg proteins per 200 μl) of the particulate fraction (15 min, 20°C) in the presence of 250 nM of purified ^{3}H-Leu-enkephalin and 1 μM *p*-chloromercuriphenylsulphonic acid (except in conditions (a)) and in the presence or absence of either Leu-enkephalin or Gly-Gly-Phe-Met. A 10 μl aliquot of the deproteinised supernatant or of the Porapak column eluate was applied on a TLC plate (plastic sheets Silicagel 60, Merck, thickness 0.2 mm). Solvent systems and R_f values of the reference compounds were: (1) $CHCl_3:CH_3OH:AcOH:H_2O$ (45:30:6:9); Tyr = 0.61, Tyr-Gly-Gly = 0.47, Leu-enkephalin = 0.88 (2) $BuOH:AcOH:H_2O$ (4:1:1); Tyr = 0.47, Tyr-Gly-Gly = 0.31, Leu-enkephalin = 0.58 (3) isopropanol : AcOEt : 5% AcOH (2:2:1); Tyr = 0.70, Tyr-Gly-Gly = 0.41, Leu-enkephalin = 0.80. Markers visualised with a ninhydrin spray and radioactive peaks at their R_f isolated by cutting the plates and counted by liquid scintillation (40% efficiency). Means ±s.e.m. of 3–6 determinations * $P < 0.025$. ** $P < 0.01$. *** $P < 0.001$. No other radioactive peak could be detected when the entire plate was counted by fractions of 0.5 cm. In particular no significant radioactivity was detected at the R_fs of Tyr-Gly-Gly-Phe (0.80 in system (1) and 0.45 in system (2)).

Table 3 Effect of chronic morphine treatment on ^{3}H-enkephalin-hydrolysing activity of particulate and soluble fractions of mouse striatum

	^{3}H-enkephalin-hydrolysing activity (d.p.m. per mg protein per min) Particulate fraction High affinity peptidase	Low affinity peptidase	Total peptidase	Soluble fraction
Controls	7,858 ± 977	33,344 ± 2,309	41,203 ± 2,620	120,990 ± 20,468
Morphine	12,521 ± 932** (+59%)	33,255 ± 1,998^{NS}	45,776 ± 2,042* (+12%)	125,297 ± 9,590^{NS}

Groups of mice were implanted under light ether anaesthesia with a morphine pellet (75 mg of base, s.c.) which was removed 3 days later, 16 h before death. Controls were sham-operated in a parallel manner. ^{3}H-enkephalin-hydrolysing activity measured after incubations of fractions prepared as described in Fig. 1 (15 min at 20°C) with 20 nM ^{3}H-Leu-enkephalin. The low-affinity hydrolysing activity of the particulate fraction represents the activity measured in the presence of 5 μM Leu-enkephalin whereas the high-affinity activity was estimated as the difference between total (in the absence of 5 μM Leu-enkephalin) and low-affinity activities. Degraded ^{3}H-Leu-enkephalin was measured by Porapak column chromatography. Means ±s.e.m. of 12–16 experiments on pooled striatal fractions from two mice. * $P < 0.05$. ** $P < 0.0005$. NS, not significant.

than the N-terminal moiety as shown by the much greater potency of the tetrapeptides Gly-Gly-Phe-Met or Gly-Gly-Phe-Leu when compared to the tetrapeptide Tyr-Gly-Gly-Phe; this conclusion does not hold true for the two classes of low-affinity peptidases.

(4) Among classical peptidase inhibitors, only bacitracin has significant potency towards the high-affinity peptidase, whereas *p*-chloromercuriphenylsulphonic acid, a potent inhibitor of the low-affinity peptidases, is practically inactive on the high-affinity enzyme; this indicates that the latter does not belong to the group of thiol-peptidases. The heterogeneity of enkephalin-hydrolysing activity as shown by response to thiol-blocking agents has been already suggested[8].

(5) Structural requirements for recognition of the opiate receptors and the high-affinity peptidase are unrelated as demonstrated by the lack of potency of α- and β-endorphin as well as opiates.

From these data it seems that three compounds are useful to differentiate the high- and low-affinity peptidase activities in the particulate fraction: Leu-enkephalin, Gly-Gly-Phe-Met and *p*-chloromercuriphenylsulphonic acid. Therefore, these compounds were used as tools in the identification of the ^{3}H-fragments released under the action of each class of peptidases in the particulate fraction.

Thin-layer chromatography of extracts (obtained after incubation of ^{3}H-Leu-enkephalin with the particulate fraction) yields three radioactive peaks with R_f values closely corresponding to ^{3}H-Leu-enkephalin, ^{3}H-Tyr and ^{3}H-Tyr-Gly-Gly (Table 2). In contrast, only ^{3}H-Leu-enkephalin and ^{3}H-Tyr were found after incubation of the soluble fraction. Whereas the presence of ^{3}H-Tyr is in agreement with a number of reports[1–5], ^{3}H-Tyr-Gly-Gly was an unexpected component. The presence of ^{3}H-Tyr-Gly-Gly was confirmed first by unidimensional TLC in three different solvent systems (Table 2), second by bi-dimensional co-chromatography in solvent systems (2) and (3), and third by high-performance liquid co-chromatography on a 205 U Waters apparatus (reversed phase on standard micro-bondapak C 18; solvent CH_3CN : 10 mM NH_4Ac buffer, 3.125 : 96.875; 1 ml min^{-1}; retention times Tyr = 290 s, Tyr-Gly-Gly = 350 s, Leu-enkephalin > 1 h).

The fact that Tyr-Gly-Gly was not previously identified by others as a breakdown product of enkephalin can easily be explained by its low level relative to total metabolites (~25% in our washed particulate fraction but only 2–3% in the whole homogenate as used by most workers). Nevertheless, the occurrence of a minor unidentified peak with R_f corresponding to Tyr-Gly-Gly has been reported in brain extracts[2], and formation of this tripeptide by cultured human endothelial cells has been reported[10].

That ^{3}H-Tyr-Gly-Gly is specifically produced by the high-affinity peptidase is clearly demonstrated by first the marked decrease observed after incubations in the presence of 5 μM Leu-enkephalin or 10 μM Gly-Gly-Phe-Met contrasting with the unchanged ^{3}H-Tyr peak in the same conditions; and second the lack of effect of *p*-chloromercuriphenylsulphonic acid on ^{3}H-Tyr-Gly-Gly formation, contrasting with the strong reduction in the ^{3}H-Tyr peak (solvent system (1)). These results indicate that the high-affinity peptidase is probably a C-terminal dipeptidase splitting the Gly–Phe bond of enkephalin, a conclusion consistent with the high inhibitory potency of the C-terminal tetrapeptide as compared to the N-terminal tetrapeptide (Table 1). As we have not yet characterised the formation of Phe-Leu or Phe-Met (because they are not labelled) we cannot exclude the possibility that ^{3}H-Tyr-Gly-Gly formation results from the sequential action of carboxypeptidases. However, this is unlikely because ^{3}H-Tyr-Gly-Gly-Phe formation was never observed in our experiments.

In mice chronically treated with morphine we observe a dramatic increase in the activity of the high-affinity peptidase in the particulate fraction (Table 3). A similar effect is also observed in rats implanted with a morphine pellet (data not shown). This effect seems to be selective because the low-affinity peptidase activity in either the particulate or the soluble fractions is unchanged. The increase in activity reflects an elevated V_{max} without significant change in K_m value (data not shown), suggesting that it corresponds to an increased number of enzyme molecules. The effect of morphine might result from a feedback mechanism operating at the target cells bearing the opiate receptors: conceivably these cells, to compensate the overstimulation of opiate receptors, could develop a state of hyposensitivity to released enkephalins, through an increased rate of inactivation of these peptides. In this respect, changes in acetylcholinesterase activity in brain have been already reported to mediate the modified responsiveness of target cells to the transmitter, developing in response to sustained changes in cholinergic transmission[11]. Although not direct proof, the effect of morphine strongly suggests that the high-affinity peptidase is involved in the control of enkephalinergic transmission. This hypothesis is consistent with the heterogeneous distribution of this 'enkephalinase' in mouse brain regions (striatum > hypothalamus > cortex > brainstem ⩾ hippocampus > cerebellum, with a five-fold variation between striatum and cerebellum) which is highly correlated ($r = 0.94$) with that of opiate receptors (manuscript in preparation). If true, this would imply that a new class of therapeutic agents (enkephalinase inhibitors) exhibiting opiate-like activity could be developed. In addition the increased peptidase activity after chronic morphine treatment could be involved, with other mechanisms[12], in the development of dependence on opiates.

The ACTH 'family tree' of the rhesus monkey changes with development

THE pituitary hormone adrenocorticotrophin (ACTH) belongs to a 'family' of peptides derived from a common 'stem hormone' (Fig. 1). Depending on the way in which the stem hormone is cleaved, the various peptides are expressed and it is possible that qualitative changes in the expression of the peptide 'family tree' may be responsible for the alteration in fetal adrenal function which precedes birth[1]. We now report evidence for such changes in the rhesus monkey, which has a fetal adrenal comparable with that of man.

After delivery the fetal zone of the human adrenal cortex involutes, while the definitive zone or adult cortex, consisting of a thin layer of cells covering the large fetal zone, hypertrophies. This change may be triggered by a switch in the production of trophic hormones in the fetus, from peptides resembling α-melanocyte stimulating hormone (α-MSH) and corticotrophin-like intermediate lobe peptide (CLIP) to ACTH[2,3]. The idea is supported by a report[4] that α-MSH stimulated the fetal adrenal gland of the rabbit when synacthen (α-1–24 ACTH) was relatively ineffective, whereas synacthen was potent in the newborn and α-MSH was ineffective. Others have shown that although ACTH stimulated the definitive zone *in vitro* its effect on the fetal zone was inconsistent[5]. The metamorphosis of the adrenal at birth is but one aspect of the change in adrenal function. In the sheep, for example, in which there is no specific fetal zone, there are nevertheless important changes in steroid output, notably a prepartum rise of cortisol which prepares the fetus for delivery and initiates parturition[6]. As with the human, there are differences in the composition of pituitary hormones between fetus and adult[1]. Unlike the human, however, it is the large molecular weight forms of ACTH which predominate in the fetal sheep. There are three such forms, two of which contain sequences common to β-lipotrophic hormone (β-LPH), γ-LPH,

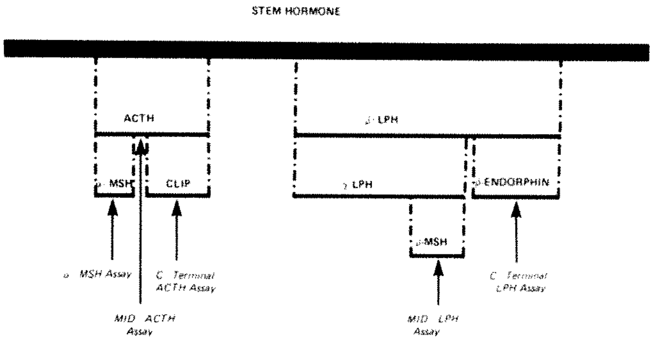

Fig. 1 The stem hormone family tree gives rise to two major branches—ACTH and β-LPH. ACTH is a 39-amino acid peptide whose first 13 amino acids are identical in sequence with α-MSH and whose 18–39 sequence is identical to CLIP. β-LPH is a 91-amino acid peptide whose first 58 amino acids are identical in sequence with γ-LPH and whose 61–91 sequence is identical to β-endorphin. The sequence 41–58 is identical to the 18-amino acid peptide β-MSH. The five radioimmunoassays are directed against different antigenic sites of this family tree.

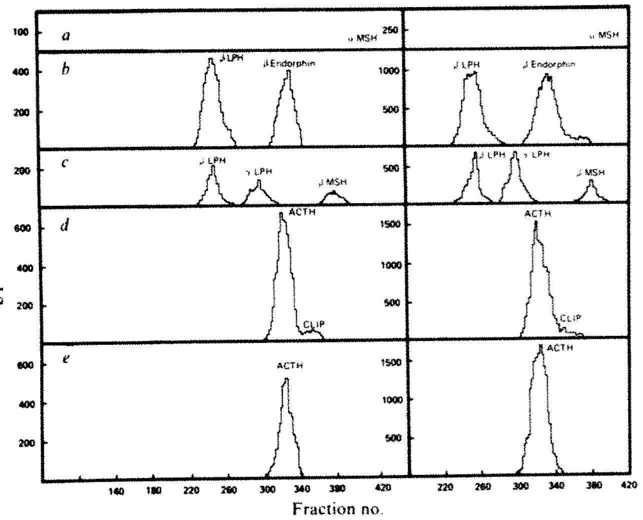

Fig. 2 Pituitary extracts from two adult monkeys (left, infant 77 days postpartum; right, mature adult) individually fractionated on Sephadex G100 superfine: alternate fractions were assayed in five systems of radioimmunoassay. *a*, α-MSH activity; *b*, C-terminal LPH; *c*, mid-LPH; *d*, C-terminal ACTH; *e*, mid-ACTH.

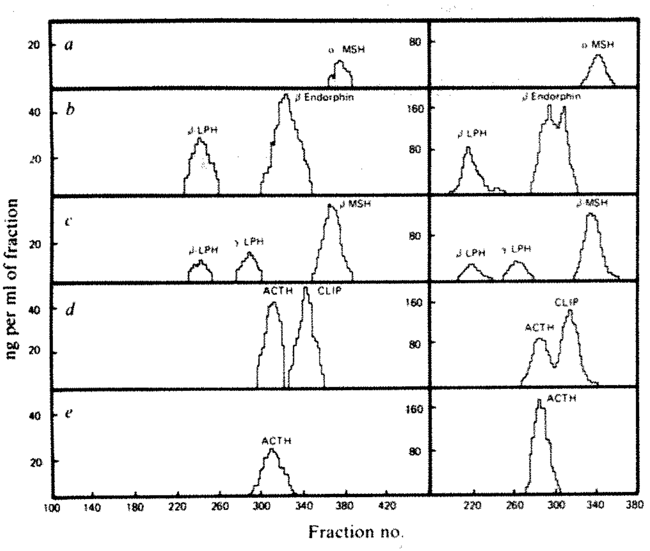
β-MSH, β-endorphin and possibly other biologically active peptides as well as ACTH, α-MSH and CLIP. These precursors are the 'stem hormones'.

We have used the pituitary of the rhesus monkey for further investigations because, in common with man, its adrenal gland has a fetal zone which involutes at birth. Dated pregnant monkeys were anaesthetised with 20 mg phencyclidine hydrochloride (Sennylan, Bioceutics). Fetuses were delivered by hysterotomy, their pituitaries freshly dissected, snap frozen in liquid nitrogen and stored at −70 °C. Pituitaries from newborn, infant, and mature adult monkeys were freshly dissected and stored at −70 °C. Pituitaries were extracted in 0.02M HCl with 10^{-3} M diisopropylphosphofluoridate, loaded on to a column (1.6 × 100 cm) of Sephadex G100 superfine and eluted in 1M acetic acid at 1.6 ml h^{-1}. Fractions were collected every 15 min and alternate fractions assayed in five systems of radioimmunoassay (Fig. 1) directed against different branches of the stem hormone family tree. The α-MSH assay measured only α-MSH and was probably directed against the acetylated or amidated end groups of the molecule. The mid-ACTH assay measured ACTH and did not cross-react with α-MSH, CLIP or the LPH family. The C-terminal ACTH assay cross-reacted with CLIP as well as ACTH. The mid-LPH assay cross-reacted with β-MSH, γ-LPH and β-LPH. The C-terminal LPH assay cross-reacted with β-endorphin and β-LPH.

Fig. 3. Pituitary extracts from two fetal monkeys (left, 145 days gestation; right, 164 days gestation) individually fractionated on G100 superfine: alternate fractions were assayed in five systems of radioimmunoassay. (*a*–*e* as Fig. 2.)



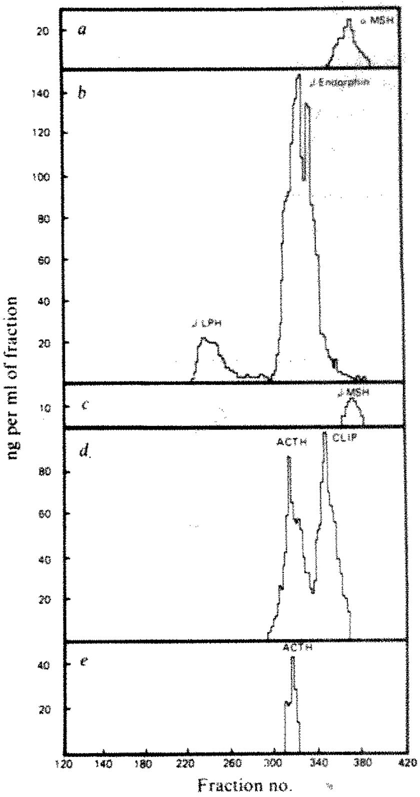


Fig. 4 Pituitary extract from a neonate (12 h postpartum) fractionated on Sephadex G100 superfine: alternate fractions were assayed in five systems of radioimmunoassay. (*a*–*e* as Fig. 2.)

The patterns of peptides seen in the pituitary of an infant and a mature adult were similar (Fig. 2). The major peak in both pituitaries was ACTH with relatively insignificant amounts of α-MSH and CLIP. Further peaks of activity were associated with β-LPH, γ-LPH, β-endorphin and β-MSH. In fetal pituitaries taken at 145 days gestation and 164 days gestation, β-MSH was increased relative to β- and γ-LPH and β-endorphin increased relative to β-LPH (Fig. 3). There was a significant peak of α-MSH and a peak of CLIP which equalled that of ACTH. A pituitary from a neonate killed 12 h after delivery also showed substantial peaks of α-MSH and CLIP compared to ACTH (Fig. 4). However, the major peak was that of β-endorphin which dominated the peaks of β-LPH, γ-LPH and β-MSH.

The fetal and adult pituitaries did not contain substantial amounts of 'big ACTH' or stem hormone. However, small quantities were identified. An extract from a mature adult pituitary showed dominant peaks of ACTH, β-LPH, γ-LPH, β-MSH and β-endorphin, plus three peaks of large molecular weight material 'A', 'B' and 'C' (Fig. 5). Small quantities of peak A were detected by the mid-ACTH assay, peak B cross-reacted in the LPH assays and the ACTH assays, peak C only cross-reacted in the ACTH assays. The position of these three peaks corresponded to material found in abundance in the fetal sheep pituitary, where A and B were characterised as stem hormones and C as big ACTH[1].

These results reveal significant alterations of the family tree at different stages of development of the monkey. As with the human, α-MSH and CLIP predominate in fetal life and all but disappear in the adult. Unlike the human, the pituitary of the rhesus monkey contains β-MSH with relatively greater amounts in the fetus than the adult. The levels of β-endorphin also appear more prominent in fetal life and it may consist of more than one molecular form. The overall picture is that the small molecular weight peptides α-MSH, CLIP, β-MSH and β-endorphin are characteristic of the fetal pituitary of the rhesus monkey, whereas in the adult pituitary the larger peptides ACTH, γ-LPH and β-LPH are the predominant forms.

Previously we have reported the occurrence of small amounts of a common precursor for ACTH and LPH in the human pituitary[7,8] and such a molecule has been identified in a mouse pituitary tumour cell line[9,10]. The stem hormones are found in abundance in the pituitary of the sheep and the fact that they can now be identified, even in small quantities, in the monkey substantiates the hypothesis that there is a family tree of biologically active peptides which derive from a common stem. The change in fetal adrenal function and morphology which precedes parturition must, therefore, be measured against the qualitative changes of the 'trophic family' as a whole.

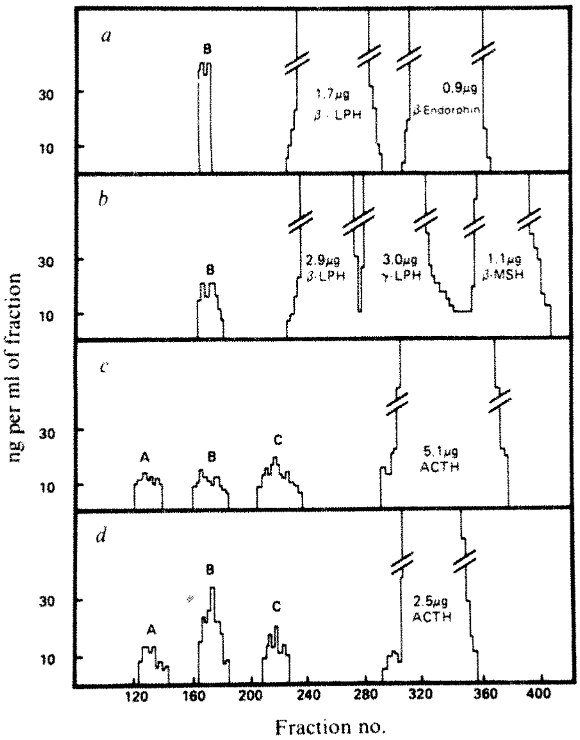

Fig. 5 Pituitary extract from a mature adult monkey fractionated on Sephadex G100 superfine. Alternate fractions were assayed in four systems of radioimmunoassay. In addition to the major peaks of ACTH, β-LPH, γ-LPH, β-endorphin and β-MSH there were three small peaks of large molecular weight material A, B and C. *a*, C-terminal LPH assay; *b*, mid-LPH; *c*, C-terminal ACTH; *d*, mid-ACTH.

There has been considerable speculation about β-endorphin since the dramatic finding that, like enkephalin[11], it can bind to morphine receptors[12–17]. The name suggests that it is endogenous morphine, but there has been little to illuminate its functional role within the mammalian neuroendocrine system. Moreover, the administration of β-endorphin has not always proved successful as an analgesic, except when given directly into the brain ventricles[18,19]. It is an unexpected finding that there is a striking increase of β-endorphin in the pituitary of the newborn monkey (Fig. 4) and this may prove of great physiological importance. Although the moment of birth has been considered a time of intense psychological trauma for the fetus[20,21], it is clearly a moment of extreme physical stress and it is possible that the fetus needs to be rendered insensitive to the assault of parturition. High levels of β-endorphin at delivery may thus serve to protect the baby against a necessary but otherwise intolerable event.

Differences in fluidity between bilayer halves of tumour cell plasma membranes

SURFACE membranes of both normal and transformed cells appear to have an asymmetric distribution of phospholipids across the bilayer[1–6]. The potential role of this distribution in platelet aggregation and in pathological conditions such as sickle cell anaemia and cell transformation has been investigated[7–9]. However, neither the structural nor functional significance of this asymmetrical distribution is understood at present. As the lipid composition of the two sides of the plasma membrane bilayer is different it seems possible that the 'fluidity' or other physicochemical properties are also different. It has been shown that the neutral zwitterionic lipids (phosphatidylcholine and sphingomyelin) are located primarily in the outer monolayer while the anionic zwitterionic lipids (phosphatidylethanolamine,

0028–0836/78/0276—0528$01.00

phosphatidylserine and phosphatidylinositol) are located primarily in the inner or cytoplasmic monolayer. In model systems the former lipids are usually more fluid while the latter lipids are more rigid[10]. Thus, a fluidity gradient could exist across the bilayer of biological membranes. Such a gradient and alterations of it may have important consequences in vectorial processes such as small molecule transport, receptor mobility, hormone receptor interactions and the activity of membrane-bound enzymes. However, as mammalian cells can compensate or homeoviscously adapt and because biological membranes are complex mixtures of cholesterol and phospholipids with different fatty acyl chain length or unsaturation, direct experimental measurement is necessary to determine if such vertical asymmetry of 'fluidity' exists across the plasma membrane bilayer of mammalian cells[11–16]. I report here use of a fluorescent probe molecule, β-parinaric acid, used in conjunction with the amino labelling reagent 2,4,6-trinitrobenzenesulphonic acid (TBNS) to investigate this asymmetry. The data obtained are consistent with the conclusion that the inner monolayer of the plasma membrane is less fluid than the outer monolayer.

LM cells (ATCC-CCL 1.2), a strain of transformed murine fibroblasts, were grown in suspension in a chemically defined medium and plasma membranes isolated as described previously[11]. The cells or isolated plasma membranes were labelled with TBNS under penetrating or nonpenetrating conditions as previously stated[5]. The computer-centred spectrofluorimeter of Holland *et al.*[12,13] was used for all fluorescence measurements[14–17].

As β-parinaric acid distributes rapidly across both sides of the plasma membrane, one method to determine the physical properties of the inside monolayer of the plasma membrane would be to quench fluorescence of the probe in one monolayer and measure the fluorescence properties of the probe in the unquenched monolayer. The amino labelling reagent TBNS can be used as such a chemical quencher of β-parinarate fluorescence on one side of the bilayer membrane. Free TBNS has an absorption maximum in aqueous solution at 340 nm. However, after reacting with free amino groups a new absorption band near 420 nm appears[18,19]. This absorption band overlaps with the lower wavelength side of the fluorescence emission spectrum of β-parinaric acid in plasma membranes and in blood lipoproteins and is therefore an ideal quenching agent if the quenching of β-parinarate fluorescence is nontrivial[14–19]. This quenching is nontrivial because the shape of the fluorescence emission curve of β-parinarate in the plasma membrane is unaltered by trinitrophenyl amino groups and the fluorescence of β-parinarate in organic solvents is quenched completely by trinitrophenylglycine, indicating high quenching efficiency of β-parinarate fluorescence by the trinitrophenyl group. If both sides of the plasma membrane were labelled by TBNS then fluorescence of β-parinarate should be quenched almost completely. When both sides of the isolated plasma membrane of LM cells are labelled with TBNS, absorption-corrected fluorescence, relative fluorescence efficiency and corrected fluorescence emission are quenched 91–95% (Fig. 1). Thus, most of the β-parinarate is accessible to quenching by energy transfer. If only the outer monolayer is labelled with TNBS, then these parameters are quenched only 44–46%. These results indicate that the trinitrophenylated amino groups of the outer monolayer cannot quench the fluorescence of β-parinarate in the inner monolayer. The data are also consistent with an approximately equal distribution of β-parinarate across both sides of the bilayer and indicate that the properties of the inner monolayer can be investigated independently of the outer monolayer.

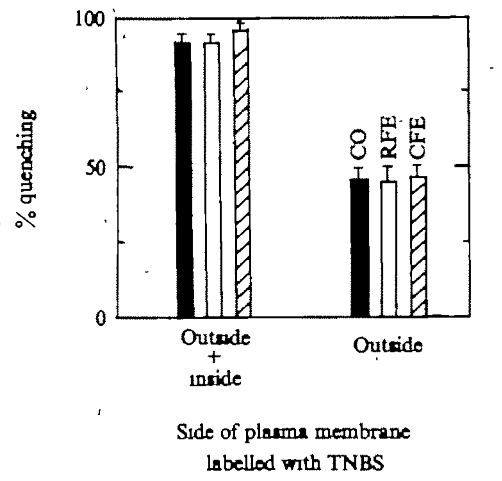

Fig. 1 Fluorescence quenching of β-parinaric acid in isolated LM cell plasma membranes by TNBS. β-parinarate quenching of outside+inside monolayers of the plasma membrane was determined as follows: plasma membranes were isolated as stated previously[11] and reacted under penetrating conditions with TNBS to trinitrophenyl-label all free amino-phospholipids in both monolayers of the plasma membrane as described elsewhere[5]. β-parinarate was incorporated into the plasma membranes at a β-parinarate/lipid molar ratio of 1:100 and absorption corrected fluorescence (CO), relative fluorescence efficiency (RFE), (CFE) and corrected fluorescence emission were determined at 313 nm, 313 nm and 415 nm respectively as described earlier[14–17]. The per cent quenching of β-parinarate was determined by comparison of the values for these fluorescence parameters with values for β-parinarate in equivalent samples that had not been reacted with TNBS. The degree of fluorescence quenching in the outside monolayer was determined by prelabelling the intact LM cells under nonpenetrating conditions with TNBS followed by membrane isolation and incorporation of β-parinarate into the membranes as above[5,14–17]. Values indicate the mean ± s.e.m. ($n = 3$) and differences in each parameter are significantly different at $P < 0.01$ by Student's *t* test. Outside and inside refer to the side of the plasma membrane labelled with TNBS

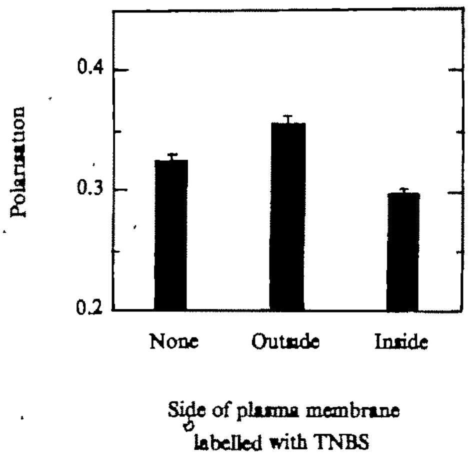

Fig. 2 Asymmetry of fluorescence polarisation between outer and inner monolayers of isolated LM cell plasma membranes. All methods were as described in the legend to Fig. 1 for [outside + inside monolayers] and [inside monolayer]. Polarisation values for the [outer monolayer] were calculated as described in the text. Polarisation was measured as described elsewhere. None, outside and inside refer to the side of the plasma membrane labelled with TNBS. Thus, polarisation values represent the side opposite to the side labelled with TNBS. Each value represents the mean ± s.e.m. ($n = 3$); all values are different at $P < 0.01$ by Student's *t* test.

The asymmetry of 'fluidity' across the plasma membrane bilayer is best demonstrated by the polarisation measurements shown in Fig. 2. Fluorescence polarisation is directly proportional to microviscosity. The polarisation of β-parinarate in plasma membranes that were not reacted with TNBS was 0.325 ± 0.005 while that in plasma membranes labelled on the outside with TNBS was 0.355 ± 0.006. The polarisation of β-parinarate in the outer monolayer can be estimated to be 0.290, using the formula $P_{\text{inside+outside}} = xP_{\text{inside}} + (1-x)P_{\text{outside}}$ (where x

is the mole fraction of β-parinarate), assuming x to be 0.5. This seems to be a reasonable assumption in view of the results shown in Fig. 1. Thus, the minimum difference in polarisation between the inner and outer monolayer would be 0.030 (if almost all of the probes were located in the outer monolayer).

The data presented here indicate that the inner monolayer of plasma membranes from a tumorigenic cell grown in tissue culture may be more rigid (lower fluidity) than the outer monolayer. The function of such a fluidity gradient across the membrane bilayer is not known. However, it is known that both in normal and transformed cells the lipid composition of the membranes can be modified by medium constituents (see ref. 11 for review). Thus, alterations in or regulation of membrane fluidity gradients may be important in membrane pathologies. In support of this, several types of fluidity asymmetries have been suggested by electron spin resonance data. Red blood cell membranes appear to have a more rigid outer monolayer than inner monolayer, a finding opposite to that presented here[20]. In contrast, sarcoplasmic reticulum membranes do not have an asymmetry of physical properties in the hydrocarbon region of the bilayer but an asymmetry similar to that presented here exists for the phospholipid polar head groups across the bilayer[21]. These results may point out basic differences in asymmetry of physical properties of membranes in mammalian cells.

This research was supported in part by National Cancer Institute grant (USPH CA 24339). I thank Dr J. F. Holland of Michigan State University for allowing me to use his computer-centred spectrofluorimeter.

A direct method for determination of membrane electron density profiles on an absolute scale

THE principal aim in X-ray diffraction studies of biological membranes and lipid bilayers is to determine the electron density profile across the membrane and to interpret this in terms of the distribution of the component molecules. The derivation of such electron density profiles requires a knowled of both the amplitudes of the X-ray reflections and their co responding phase angles. Although the relative amplitudes c be easily determined from a diffraction pattern, the phases of t reflections cannot be directly observed. The determination these phases has proved to be one of the most difficult ar contentious aspects of the membrane diffraction field[1–9]. I addition, because of the difficulty in measuring absolu intensities[10,11], the profiles are, almost invariably, calculated c a relative electron density scale. The lack of an absolute scale h often greatly hindered the interpretation of membrane profile particularly with regard to the distribution of the prote molecules[9,12–16]. We describe here a novel method of direct determining both the phases of the X-ray reflections and a absolute electron density scale, and how the method has bee successfully tested on lecithin/cholesterol bilayers.

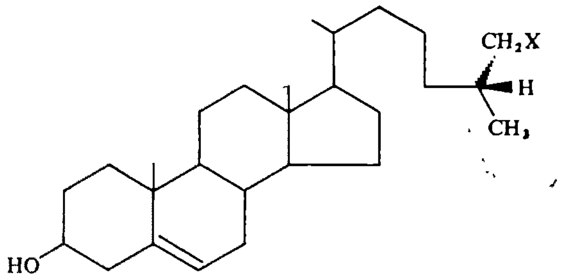

Fig. 1 The cholesterol analogue used to introduce a halogen atom into the bilayer. X is either bromine or iodine. The molecule is identical to cholesterol except for the exchange of a hydrogen atom on C-26 by the halogen. The (25*R*)-26-bromocholesterol, melting point 134–136 °C, NMR δ 3.32 (d, $J = 6$ c.p.s., $-CH_2Br$), was made by treating (25*R*)-26-hydroxycholesterol (prepared from kryptogenin) with *N*-bromosuccinamide and triphenylphosphine in tetrahydrofurane. Similarly, treatment of (25*R*)-26-hydroxycholesterol with *N*-iodosuccinamide and triphenylphosphine in tetrahydrofurane gave the (25*R*)-26-iodocholesterol, melting point 118–120 °C, NMR δ 3.2 (d, $J = 6$ c.p.s., $-CH_2I$).

The basis of the method is the isomorphous exchange cholesterol in the membrane with a cholesterol analogue whi is halogenated at C-26 (see Fig. 1). The introduction of th molecule into the membrane places an electron-dense ato close to the bilayer centre. Figure 2 shows schematically how t introduction of such a heavy atom affects the diffraction patte for the simple case of a unit cell containing a single centr symmetric lipid bilayer. Provided that the heavy atoms lie clo enough to the bilayer centre, they will make only a positi contribution to the Fourier transform of the unit cell. When t halogen atoms are added, all reflections which have positi signs will increase in intensity, and the intensity of all those wi negative signs will decrease. The phases of weak reflection which may pass through zero on addition of the halogen atom can be checked by an experiment in which only half the origin number of heavy atoms are introduced.[17] Thus, all the phas can be directly inferred simply from the changes in intensity th occur when the halogen atoms are added to the bilayer.

If the observed electron density profiles for the control ar heavy atom unit cells are on the same relative scale, then multiplicative scale factor K will relate this scale to the absolu electron density scale. The value of K is easily obtained from t observed difference electron density profile, as the area und this profile is simply related to the total number of halog electrons in the heavy atom unit cell. If the area under t difference profile, the mass density of the bilayer and t lamellar spacing are measured, and the contents of the unit c are known, then K can be evaluated. However, the profile c still be translated with respect to the absolute scale. Its positi on the scale can be fixed by knowing the absolute electr density of any point on the prof as the water layer) or the mean electron density. An abs ale for the bilayer is thus established.

This method of determini phases of the X-ray reflections and an absolute elec sity scale for the bilayer was tested on a lipid multilayer composed of dimyristoyl lecithin and 40% (molar) terol. High-resolution diffraction patterns were record multilayers in which all, or a fraction of, the cholesterol es had been replaced by either 26-bromocholesterol or cholesterol (see Fig. 1). All the diffraction patterns wer atively the same. They showed 12–13 orders of a lamel ng of about 50 Å and a broad, equatorially orientated b 5 Å which showed the hydrocarbon region to be in a flui When the cholesterol in the bilayers was replaced by hal cholesterol, the principal difference observed in the d pattern was a change in the relative intensities of the peaks.

The introduction of either the or iodine analogues did not affect the higher orders, ged the intensities of the first seven orders; these w signs according to whether their intensity had i (positive sign) or decreased (negative sign). The ph nments were verified by repeating the experiments with n which only half the cholesterol molecules had been e with the cholesterol analogues. The signs for all the o he control data have been independently determined by an extensive series of swelling experiments (N.P.F. and Lieb, unpublished) and are consistent with those determined here.

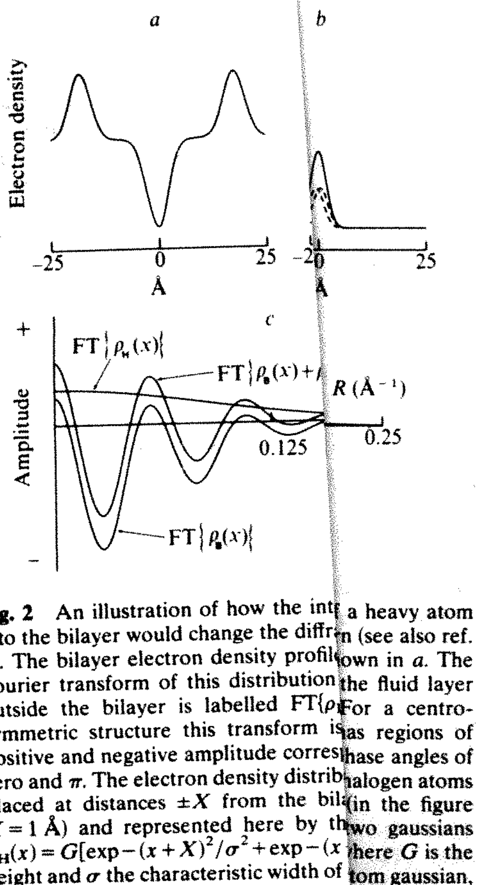

Fig. 2 An illustration of how the int a heavy atom into the bilayer would change the diffr n (see also ref. 8). The bilayer electron density profil own in *a*. The Fourier transform of this distribution the fluid layer outside the bilayer is labelled FT{ρ For a centrosymmetric structure this transform is as regions of positive and negative amplitude corres hase angles of zero and π. The electron density distrib halogen atoms placed at distances ±*X* from the bil (in the figure $X = 1$ Å) and represented here by th two gaussians $\rho_H(x) = G[\exp -(x+X)^2/\sigma^2 + \exp -(x$ here *G* is the height and σ the characteristic width of tom gaussian, is shown in *b*. The Fourier transform of ed FT{$\rho_H(x)$} in *c* and is of the form

$$FT\{\rho_H(x)\} = F(R) = 2G\sqrt{\pi}\sigma \exp -2\pi RX)$$

where *R* is the reciprocal space coordin e addition of the halogen atoms to the bilayer results i on to the unit cell Fourier transform which is a gaussia off slowly if the halogen atoms are well localised) m cosine term with a wavelength of $1/X$. The halogen at efore make a positive contribution to the unit cell tra a reciprocal space coordinate $R = 1/(4X)$, at whic cosine first changes sign and the transform becomes e figure this occurs at $R = 0.25$

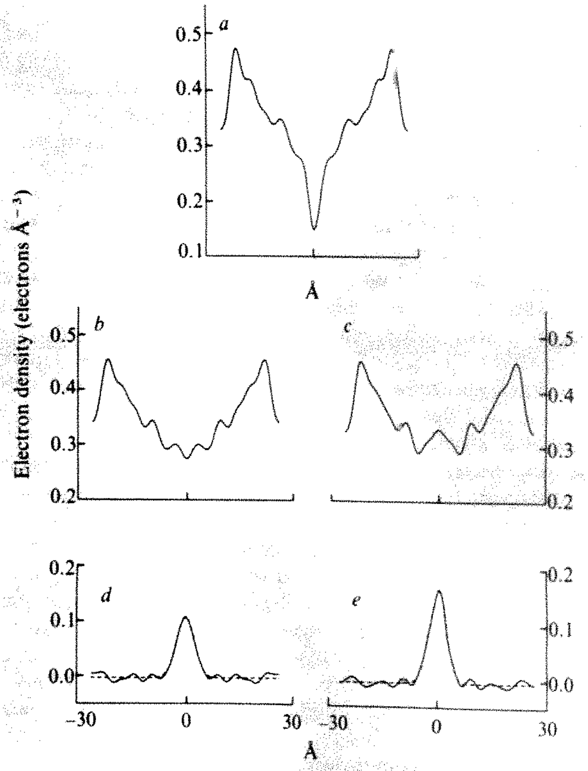

Fig. 3 Absolute electron density profiles of bilayers composed of dimyristoyl lecithin and 40% (molar) of *a*, cholesterol; *b*, 26-bromocholesterol; *c*, 26-iodocholesterol. The difference electron density profiles are shown in *d* and *e*. The profile of the bilayers containing 26-bromocholesterol is for a lamellar spacing of 52.12 Å and that of the bilayers containing 26-iodocholesterol is for a spacing of 53.20 Å. Profiles for bilayers containing normal cholesterol were calculated at both of these spacings using the swelling series data of N.P.F. and Lieb (ref. 18 and unpublished data). The determination of the absolute electron density scale is described in the text. The water contents of the multilayers were measured gravimetrically and the mass densities determined using an Anton–Parr precision density meter (we found $d_{\text{normal}} = 1.035\ \text{g cm}^{-3}$, $d_{\text{bromo}} = 1.074\ \text{g cm}^{-3}$ and $d_{\text{iodo}} = 1.090\ \text{g cm}^{-3}$). The cross-sectional areas of the unit cells (one lecithin plus 2/3 of a cholesterol) were calculated to be $A_{\text{normal}} = 67.31\ \text{Å}^2$, $A_{\text{bromo}} = 68.25\ \text{Å}^2$ and $A_{\text{iodo}} = 69.22\ \text{Å}^2$. The mean electron densities for the bilayers were 0.345, 0.355 and 0.357 electrons Å^{-3}, respectively, for the control, the bilayers containing 26-bromocholesterol and the bilayers containing 26-iodocholesterol. The assignment of phases for the first seven orders is described in the text; the phases for the higher orders were determined from swelling series and this work will be described elsewhere (N.P.F. and Lieb, in preparation). The samples were prepared on curved glass substrates from solutions of the lipids in 10:1 (v/v) chloroform/methanol as described previously[22]. The essential details of the experimental method and the correction of the diffracted intensities have been described previously[6].

The electron density profiles for lecithin/cholesterol bilayers containing normal cholesterol, 26-bromocholesterol and 26-iodocholesterol are shown in Fig. 3*a–c*. Ignoring for the moment how the absolute electron density scales in Fig. 3 were determined, consider first the general features of the profiles. The control electron density distribution of Fig. 3*a* shows a familiar bilayer profile with peaks at about ±22 Å from the bilayer centre, due to the phosphate groups of the lecithin molecules, and a well defined trough of low electron density in the centre of the bilayer where the terminal methyl groups are localised. The most striking change in the electron density profile that occurs when normal cholesterol is exchanged with either of the halogenated analogues is the large increase in electron density in the centre of the hydrocarbon region (see Fig. 3*b*,*c*). This large change is accompanied by a small, but significant, smoothing of the fine detail in the profiles, interpreted as a small increase in disorder in the bilayer due to the introduction of the halogen atoms. Note that, apart from this slight overall increase in disorder, the effects of the halogen atoms are confined to a narrow region near the bilayer centre; the appearance of the head-group region and the distance across the bilayer between the phosphate groups remain unchanged.

Small increases in cross-sectional area were observed when the halogen atoms were added. This is consistent with the increased disorder observed in the one-dimensional electron density profiles. The scale factor between the control and heavy atom profiles was refined by minimising the difference in the profiles over the head-group region. The observed increase in disorder was accounted for in the refinement by applying a imple gaussian temperature factor[19] to the control profile. Both his temperature factor and the scale factor were allowed to vary as to minimise the difference.

The difference electron density profiles are shown in Fig. 3*d* d *e*. The electron density added to the bilayer by the introction of the halogen atoms can be clearly seen to be confined region near the bilayer centre, the ripple in the background ng within experimental error. The dashed line with each rve is the predicted electron density profile for a gaussian tribution of the appropriate halogen atoms placed at mean sitions $\pm X$ from the bilayer centre. For both bromine and line, excellent agreement is obtained between the observed d predicted profiles when X is 0.8 Å and 0.2 Å, respectively, th a Debye–Waller temperature factor of 420 Å^2.

In order to put the profiles of Fig. 3 on an absolute electron ensity scale, the multiplicative factor K was first evaluated. It was found that the scale factor for the two halogens agreed to within 4%, thus giving a measure of the overall precision of the absolute scale determination. The mean of the two values was used for the scale shown in Fig. 3. Having determined the multiplicative scale factor the profiles could be fixed on the scale by using the calculated values for the mean electron densities of the bilayers. Where comparison can be made (for example, for the lecithin head-group region) the electron density scale derived here agrees well with values deduced from partial specific volume data and crystallography[20,21]. The absolute scale imposes important constraints on molecular models of these bilayers. We hope that this new method of determining phases and an absolute electron density scale will be extended and applied to both natural membranes and to protein-containing model systems.

We thank Professor M. H. F. Wilkins for support and encouragement, Professor D. M. Blow, and Drs S. D. Dover, W. R. Lieb and A. J. Wonacott for discussions and helpful comments on the manuscript, and in particular Mr R. F. Danielli, whose early contribution provided a stimulus to the project. N.P.F. was the recipient of an MRC training fellowship. The work at the Worcester Foundation for Experimental Biology was supported by NIH grant HD 08194 and by institutional funds.

Role of DNA poase γ in adenovirus Dplication

THE linear DNA of th adenoviruses type 2 and type 5 (Ad2, Ad5) replicat ucleus of permissive cells by a mechanism different f of chromosomal DNA or papovavirus DNA. Papov plicate bidirectionally, with both parental strands be ated almost synchronously, whereas adenovirus DNA n occurs unidirectionally by a strand displacement m No new DNA polymerase has been observed in Ad cells[2]. To determine which cellular DNA polymera uired for adenovirus DNA replication we used the analogue 2′,3′-dideoxythymidine triphosphate (dd h inhibits DNA polymerase β, and in particular DN rase γ but not DNA polymerase α (refs 3, 4). Add TTP to isolated nuclei which synthesise adenovirus D results in a strong inhibition. In similar conditions ce or SV40 DNA synthesis is not affected. In view of e of DNA polymerase α and γ, but not β, in adenovi tion complexes[5,6] our results indicate that only DNA e γ is required for adenovirus DNA chain growth.

KB cells were infec Ad5 or Ad2 and 16 h after infection, when viral D ation is maximal, nuclei were isolated. The nuclei we d at 32 °C in the presence of the ingredients neces *vitro* DNA synthesis[7] and various concentrations ^{3}H-dGTP was used as the radioactive label and P and dTTP were present at 50 µM. After 30 min t was stopped, viral DNA was selectively extracted -dGMP incorporation was measured after precipi chloroacetic acid. The results (Fig. 1) show that ade A synthesis is very sensitive to ddTTP, with 50% i a ratio (ddTTP)/(dTTP) = 1.4×10^{-2}. Cellular D is is not inhibited up to a ratio (ddTTP)/(dTTP) = 20 dATP is used as nucleotide analogue, instead of ilar results are obtained (data not shown).

We have also stu ect of ddTTP in nuclei from primary monkey cell These cells are permissive for SV40 but are semi-p adenovirus infection, caused by a block in some without affecting viral DNA synthesis[8,9]. Hence, provide the possibility to study the effect of ddTTP ent viral systems in one type of host cell. Figure 1 s so in AGMK cells Ad5 DNA synthesis is very sens TP while SV40 DNA synthesis is only inhibited whe resent in at least 20-fold excess compared to dTTP. s the results of Edenberg *et al.*[3] for SV40 DNA syn lear lysates.

0028–0836/78/0276—0532$01.00

The inhibition of adenovirus DNA synthesis *in vitro* is independent of the time of incubation and can be suppressed by an excess of dTTP. At 500 μM dTTP, 1 μM ddTTP inhibited only 4% while at 50 μM dTTP 60% inhibition was observed, with the same concentration of ddTTP. Evidence for the competitive character of ddTTP inhibition was obtained by varying the nucleoside triphosphate concentration (S) in the presence of different ddTTP concentrations. Straight parallel lines were observed when S was plotted against S/V (not shown), giving an apparent K_m of 1.1 μM for dNTP and a K_i of 0.08 μM for ddTTP.

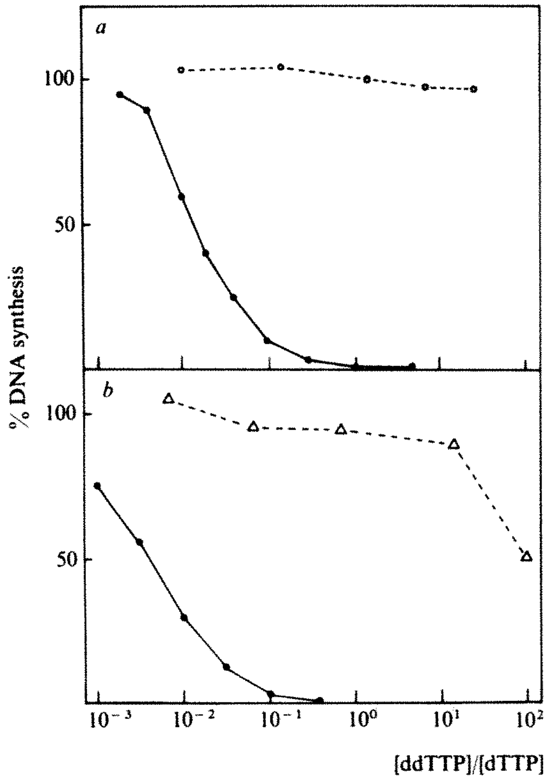

Fig. 1 Inhibition of adenovirus DNA synthesis in isolated nuclei by ddTTP. KB cells (*a*) or AGMK cells (*b*) were infected with Ad5 (○) or SV40 (△). At 16 h (Ad5) or 40 h after infection (SV40) the cells were collected and nuclei were prepared[7]. The nuclei were incubated in a final volume of 0.1 ml (2×10^7 nuclei per ml) in a reaction mixture for DNA synthesis, containing ddTTP (PL Biochemicals) as indicated. Final concentrations were 40 mM *N*-2-hydroxyethylpiperazine *N*′-2-ethane sulphonate (*p*H 7.8), 55 mM NaCl, 45 mM KCl, 5 mM $MgCl_2$, 0.4 mM $CaCl_2$, 1 mM dithiothreitol, 1 mM phosphoenol pyruvate, 2 mM ethylene-glycol tetra-acetate, 2 mM ATP, 0.05 mM each UTP, CTP, GTP, dATP, dCTP, dTTP, and 1 U ml^{-1} pyruvate kinase. ^{3}H-dGTP was present at 5 μM and 2 Ci $mmol^{-1}$. After 30 min at 32 °C the reaction was stopped by addition of 1 ml of 0.01 M Tris-HCl (*p*H 7.5), 0.01 M EDTA and cooling. To uninfected or Ad5-infected nuclei 1 ml 10% TCA containing 0.01 M sodium pyrophosphate was added. After 15 min TCA-precipitable material was collected on Whatman GF-C filters, washed with 50 ml 0.5% TCA–1 mM sodium pyrophosphate and with 96% ethanol, dried and counted in a liquid scintillation counter. From part of the nuclei, before addition of TCA, Ad5 DNA was selectively extracted[7] and the viral nature of the newly synthesised DNA was established by CsCl gradient centrifugation. SV40 DNA synthesis was determined by extraction of the DNA[17] followed by TCA precipitation. Part of the SV40 DNA was analysed by sucrose gradient velocity sedimentation in the presence of ^{32}P-labelled marker DNA. The DNA sedimented at 22–28 S with a pattern characteristic for SV40 DNA synthesised *in vitro*[18]. 100% = 20,530 c.p.m. per 10^6 nuclei (Ad5), 2,530 c.p.m. per 10^6 nuclei (uninfected) and 7,241 c.p.m. per 10^6 nuclei (SV40). ○, Uninfected KB cells.

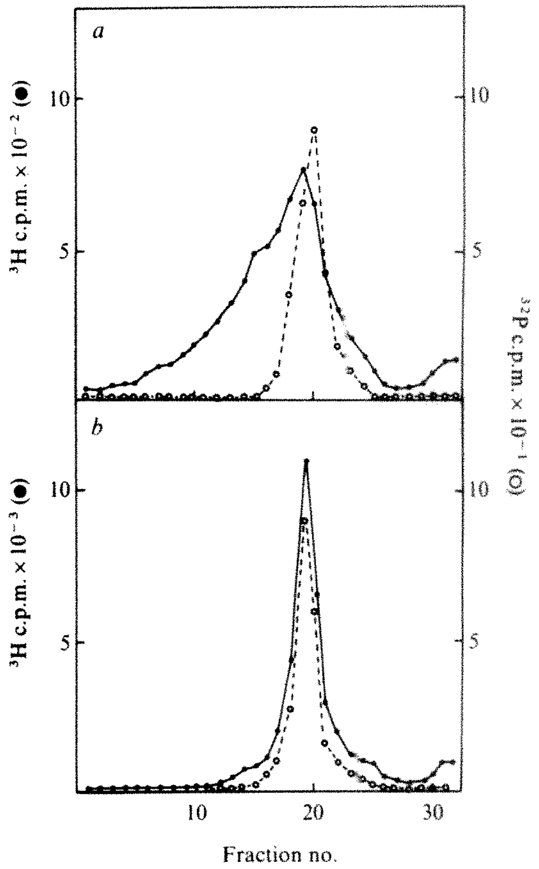

Fig. 2 Neutral sucrose gradient sedimentation of adenovirus DNA synthesised in isolated nuclei in the presence (*a*) or absence (*b*) of ddTTP. KB cells were infected with Ad5 and 16 h after infection nuclei were isolated. The nuclei were incubated as described in Fig. 1 in the presence of 2 μM ddTTP ((ddTTP)/(dTTP) $= 4\times10^{-2}$) which gives 80% inhibition compared to the control, without ddTTP. Viral DNA was extracted[7] and dialysed against 0.01 M Tris-HCl *p*H 8.0–0.01 M EDTA-1M NaCl. Samples obtained from 2×10^6 nuclei were mixed with ^{32}P-labelled Ad5 DNA and layered on a 5–27% isokinetic sucrose gradient in 0.01 M Tris-HCl *p*H 8.0–0.01 mEDTA–1 M NaCl–0.1% Sarkosyl. Centrifugation was performed for 16 h at 24,000 r.p.m. at 4 °C in a SW 41 rotor. Sedimentation is from right to left. When tested in a CsCl equilibrium centrifugation run all ^{3}H-labelled DNA had the expected density of Ad5 DNA, 1.761 g cm^{-3}.

To study the mechanism of inhibition, Ad5 DNA synthesised in the presence of 2 μM ddTTP, which gives 80% inhibition, was analysed by neutral sucrose gradient centrifugation (Fig. 2). 67% of the newly synthesised DNA sedimented between 31S and 68S, which is the sedimentation range of replicative intermediates, while in the control, without ddTTP, only 7% replicating DNA was found. In alkaline conditions, the viral DNA made in the presence of ddTTP appeared as molecules smaller than genome length (data not shown). These results can be explained by assuming that ddTMP is incorporated into growing DNA chains and acts as a chain-terminator, a mechanism that is proposed for the action of ddTTP on DNA polymerase I of *Escherichia coli*[10] and for the effect of ddTTP on ΦX174 DNA replication in permeabilised *E. coli*[11].

DNA polymerases α, β and γ from CV1 cells or HeLa cells can be distinguished by their different sensitivity to ddTTP[3,4]. We have confirmed these results with purified KB-DNA polymerases (Fig. 3). DNA polymerase α is most resistant with 50% inhibition at (ddTTP)/(dTTP) = 30. DNA polymerase β is partially resistant (50% inhibition at (ddTTP)/(dTTP) = 1) while DNA polymerase γ is most sensitive. When assayed with activated DNA in the presence of 5 mM Mg^{2+}, 50% inhibition was found at $(ddTTP)/(dTTP) = 6 \times 10^{-2}$ while in the presence of poly (rA)·oligo(dT) as template-primer and 0.5 mM Mn^{2+}, the preferred test conditions for DNA polymerase γ, the enzyme was inhibited even more markedly by the nucleoside analogue. A similar result was obtained with ddATP as inhibitor in the presence of activated DNA.

In view of the large difference in sensitivity between DNA polymerases α and γ and the specific inhibition of adenovirus DNA synthesis by ddTTP and ddATP, our results can be best explained by assuming that DNA polymerase γ is required for chain elongation of adenovirus replicative intermediates. The concentrations of ddTTP giving 50% inhibition of both adenovirus DNA synthesis and DNA polymerase γ activity are of the same order of magnitude and ddTTP behaves as a competitive inhibitor in both situations. Caution is required, however, when extending results obtained with purified enzymes to the more complicated situation that exists in the replication fork. A function of DNA polymerase β in viral DNA chain growth is less likely since only α and γ enzymes are found in replication complexes capable of elongation[5,6] and since adenovirus DNA synthesis is sensitive to low concentrations of *N*-ethylmaleimide, which do not inhibit DNA polymerase β activity.

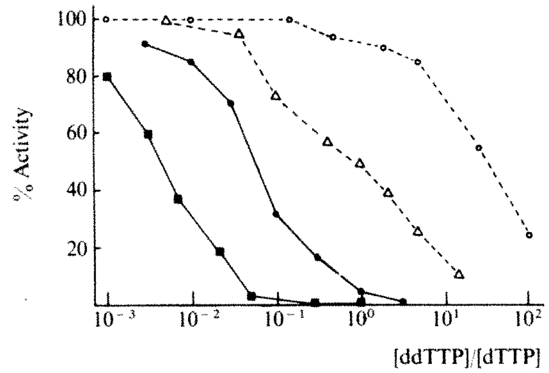

Fig. 3 Effect of ddTTP on DNA polymerase α, β and γ. DNA polymerases α and β from KB cells were purified by DEAE cellulose and DNA cellulose chromatography[2]. DNA polymerase α was characterised by sedimentation (8.8S) and its sensitivity to *N*-ethylmaleimide (95% inhibition by 1 mM NEM). DNA polymerase β sedimented at 3.4S and was completely resistant to 5 mM NEM. DNA polymerase γ was isolated according to Knopf *et al.*[19] and purified by DEAE-cellulose, phosphocellulose, hydroxylapatite and DNA cellulose chromatography. The enzyme preferred poly (rA)·oligo(dT) as template-primer to activated DNA, was 85% inhibited by 5 mM NEM and was essentially free of contaminating DNA polymerase α of β, as indicated by the absence of remaining enzyme activity at a (ddTTP) to (dTTP) ratio >1. The DNA polymerases were tested[19] with 5 mM NEM present in the β-polymerase incubation mixture. ○, DNA polymerase α; △, DNA polymerase β; ■, DNA polymerase γ with poly $(rA)-dT_{12-18}$ as primer-template; ●, DNA polymerase γ with activated DNA as primer-template.

The function of DNA polymerase γ in the cell is unknown. Recently, several laboratories[12–14] have described the identical properties of nuclear DNA polymerase γ and mitochondrial DNA polymerase. Interestingly, both mitochondrial DNA[15] and adenovirus DNA replicate unidirectionally according to a strand-displacement mechanism, in contrast to nuclear DNA synthesis or papovavirus DNA replication. Another significant difference is the absence of histones in intracellular adenovirus DNA[16]. The above differences, together with our results, indicate the presence of at least two enzymatically distinguishable replication mechanisms in the mammalian cell.

We thank Drs H. S. Jansz and J. S. Sussenbach for discussions, Dr K. Geider for ddTTP, Dr J. ter Schegget for SV40, and Dr A. de Jong for DNA polymerase α. This work was supported by the Netherlands Foundation for Chemical Research and the Netherlands Organization for the Advancement of Pure Research.

Errata

In the article 'Nucleotide sequence of bacteriophage G4 DNA' by G. N. Godson, B. G. Barrell, R. Staden and J. C. Fiddes, *Nature* **276,** 236–247, the two sentences starting on line 2 of page 242 should read: 'The amino acid differences between the proteins of the two phages is shown in Table 1. Gene *D* is the most highly conserved protein between the two phages, with only 17.8% of the amino acids changed, but this may be partly due to the presence of the overlapping *E* gene within the gene *D* coding region (see below).'

In the letter 'Are receptor-activated ciliary motor responses mediated through voltage or current?' by J. de Peyer and H. Machemer, *Nature* **276,** page 285, the last sentence in paragraph 1 should read: 'This is the first report of intracellularly recorded receptor currents in ciliates.'

In the letter 'Site of $1,25(OH)_2$-vitamin D_3 synthesis in the kidney' by M. G. Brunette *et al.*, *Nature* **276,** page 287, line 16 in paragraph 3 should read: 'were less readily digested by collagenase, and could *not* be dissected'

In the letter 'An ultraviolet subdwarf companion to HD17576' by J. Darius and P. A. Whitelock, *Nature* **275,** page 428, Fig. 2 was printed without the diamond symbol representing the position of HD17576. The figure is shown correctly below.

Large circles on the Earth's surface

AT the 3rd International Conference on Basement Tectonics in Durango on 15–19 May 1978, slides of the large circles in Arizona described by Saul[1] were shown. Several viewers pointed out that the largest circle in Fig. 1 of this paper had also been seen on satellite (Landsat) images, contrary to Saul's experience, and that such images are advantageously used in conjuction with the photographs of raised relief maps.

1 Saul, J M *Nature* 271, 345–349 (1978).

SAUL REPLIES—Several investigators have noted that some of the strongest circles are visible on satellite photographs and that some are also discernible on geological and tectonic maps. Satellite photographs of areas that have partial snow cover seem particularly useful. At present the original photomaps made by James Lindsay seem to be the most informative. Lindsay had noted the largest circle in Fig. 1 ref. 1 several years ago as well as strong linear features, some of which have apparently not been noted on more conventional types of coverage. The appearance of these linear features is strongly dependent on the direction of lighting. Several people pointed out circular features in the Canadian Shield, South Africa, East Africa, South Australia and the Himalayan region but these were found on a great variety of maps, photographs and plots, and their identity with those produced by photographing raised relief maps was surmised rather than demonstrated. One of the most interesting was the circular pattern noted by G. A. Kellaway for tin lodes in Cornwall. S. Parker Gay, Jr has identified large circles using the techniques he has developed for viewing geophysical data and topographic information in stereoscopic pairs[2].

Lifetime of an elliptical ring around Uranus

LUCKE[1] suggests that Uranus' ε ring is composed of particles in elliptical orbits, with slightly different eccentricities and nearly perfect alignment of orbital axes. This model can fit observational data[2–4] obtained in 1977 during the occultation of the star SAO158687. We point out that the model probably works only if the ring is a short-lived configuration, because perturbations due to Uranus' oblateness quickly change the shape of the ring.

If we consider the precession period P of apsidal lines in a ring lying in the planetary equatorial plane, we have

$$P \simeq \frac{4\pi a^{7/2}(1-e^2)^2}{3J_2R^2(GM)^{1/2}} \simeq 98\text{ d} \qquad (1)$$

where M, R, J_2 are the mass, radius and form factor of Uranus respectively (this latter is not well known; we use a typical value of 0.01 (ref. 5)); a and e are the semimajor axis and eccentricity of the satellite particle. If two particles in the ε ring have semimajor axes and eccentricities differing by Δa and Δe, the precession periods differ by a quantity

$$\Delta P = \left(\frac{7\Delta a}{2a} - 4\frac{e\Delta e}{(1-e^2)}\right)P \qquad (2)$$

and a randomisation of axis direction is likely to occur in a time

$$T \simeq P^2/\Delta P = P\Big/\left(\frac{7\Delta a}{2a} - 4\frac{e\Delta e}{1-e^2}\right) \qquad (3)$$

It is unlikely that all pairs of particles have orbits with a and e differing by just the quantity needed to make the denominator of equation (3) very small. Therefore, an upper limit on T may be obtained by assuming $\Delta a \simeq 0$, $e \simeq 0.008$ and $\Delta e = 0.0005$ (the latter values are chosen to account for the width variation of the ring[1]). We get in this case $T \simeq 6.3\times10^4\,P \simeq 16{,}900$ yr. A more reliable value of T may be obtained if we consider that interparticle collisions are not likely to allow $\Delta a \simeq 0$; for $\Delta a/a \simeq 10^{-3}$ (which corresponds to the width of the ring), we get $T \simeq 300\,P \simeq 80$ yr.

A similar phenomenon occurs if the ring lies out of the equatorial plane. In this case, the precession of the line of nodes yields, in a time of the order of T, a symmetrical band (with respect to the equatorial plane) that subsequently flattens out as a result of inelastic collisions among particles[6].

We conclude that the ε ring, if composed of particles in elliptical (or inclined) orbits around Uranus, may be only a transient phenomenon, and that the ring perhaps evolves in a way which may be observed.

We thank G. Colombo for useful discussions.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted Neither contribution nor reply (if one is necessary) should be longer than 300 words, and the briefest of replies, to the effect that a point is taken should be considered.

Why should the genome congeal?

A NUMBER of theoretical studies during the past decade have dealt with the problem "Why does the genome not congeal?"[1] that is, why are co-adapted gene combinations repeatedly reshuffled? As a result, specific conditions which may favour recombination have been de-

0028–0836/78/0276—0303$01.00

, such conditions are
only to restricted seg-
e. Therefore, selection
ination should be the
an the rule and hence
s conclusion "such models explain why the genome does not congeal, but not why recombination is as free as it is"[9]. This discrepancy between the observed and expected recombination frequencies may stem from an oversimplification inherent in the theoretical approach; namely, the consideration that recombination within a given chromosomal region is independent of other regions. This assumption may be unfounded in view of increasing data clearly indicating the interrelation of recombination frequencies within different chromosomal regions.

A recombination control system[10] involves controlling elements (genes determining recombination frequencies) and controlled elements (chromosomal sites recognised and acted upon by the products of specific controlling genes). The recognition sites of any recombination control system are not necessarily linked to the controlling genes, but may be distributed over the entire genome. Consequently several unlinked regions may be controlled by the same gene, as demonstrated in *Schizophyllum*[11–13] and *Neurospora*[14,15]. On the other hand, a chromosomal segment flanked by any two recombining markers, A and B, may well include recognition sites pertaining to different control systems. Thus, recombination rates between two particular markers may be influenced by several different controlling genes, a situation known to exist in *Schizophyllum*[16,17], *Tribolium*[18] and *Neurospora*[14].

If the region between A and B includes recognition sites for the controlling loci C_1, C_2 and C_3, recombination between A and B will be influenced by the particular alleles at C_1, C_2 and C_3. Selection favouring recombination between A and B may lead to an increase in the allelic frequencies of high recombination alleles at all three loci. As these loci control recombination rates in additional regions as well, any increase in high recombination alleles may elevate recombination rates in regions other than A–B. Consequently, selection favouring recombination within a particular chromosomal region may result in increased recombination rates elsewhere. Therefore, high recombination frequencies between two given markers may occur as an indirect result of selection favouring recombination in another region. Theoretically, the same indirect effect should also be apparent when recombination within a given region is disadvantageous. However, since low recombination rates are directly selected for over most of the genome, the indirect effect of selection against recombination is expected to be less obvious.

Practically all investigations of naturally occurring recombination-control genes conclude that low recombination is dominant to high (as shown in *Neurospora*[15], *Tribolium*[18], *Ustilago*[19], *Drosophila*[20] and *Schizophyllum*[21]). These experimental results concur with the theoretical model[6] predicting that individual selection for recombination would favour recessive high recombination alleles.

Dominance relationships between controlling alleles are particularly relevant to two aspects of selection affecting recombination rates. First selection against a recessive trait. Selection against recombination is essentially selection against a recessive trait[15,18–21]; a process rarely culminating in fixation. Therefore, high recombination alleles would remain in the gene pool despite vigorous and long-term selection against recombination. Second, the 'hitchhiking effect': Strobeck *et al.*[5], proposing hitchhiking as the mechanism for the propagation of high recombination genes, had to assume close linkage between the controlling gene(s) and the recombining markers. This assumption considerably weakens the efficiency of selection favouring recombination. However, if high recombination is indeed recessive, this assumption is unnecessary. In that case, an individual producing recombinant gametes must be homozygous at the controlling locus (loci) and the recombinant gamete will necessarily carry the high recombination allele(s). Consequently, selection favouring recombinants will result in the increase of high recombination allele frequency, regardless of its linkage relationship with the recombining markers.

Selection affecting recombination rates is operant on various levels. The rate of recombination between A and B may be altered by allele substitution at any of the relevant controlling loci. Alternatively, recombination frequency may be affected by changes in recognition sites lying between loci A and B. Although the nature of these recognition sites is still unknown, there is evidence that genetic control of recombination requires specific combinations of nucleotide sequences on the two homologues involved[22]. A particular sequence on one chromosome only is insufficient, thereby simulating a relationship paralleling, though not identical to, recessivity. Therefore, the situation concerning recognition sites may be similar to that of controlling genes, as far as the efficiency of selection against them is concerned.

The genetic control of recombination has evolved into a system that practically ensures the almost infinite storage of a high potential of recombination. In such a system, no population can effectively eliminate the controlling and controlled elements for high recombination. Consequently, even though selection favouring recombination is weak, transient and localised, it may well balance the persistent selection pressure against recombination.

MAYNARD SMITH REPLIES—Dr Schaap makes two points. First, as loci affecting recombination do so in more than one region, higher recombination in any one region can be increased by selection, not only on the region itself, but at many others. Hence, she suggests, the total selection for higher recombination may be stronger than one would think from simple models. This is true enough. The snag is that the same is true of selection for lower recombination. I do not understand her argument that "since low recombination rates are directly selected for over most of the genome, the indirect effect of selection against recombination is expected to be less obvious".

Her second point, that alleles for higher recombination are usually recessive, is an interesting one, because selection for higher recombination arising from 'hitchhiking' is more effective in these circumstances. This tends to confirm my conviction that hitchhiking effects are the main ones responsible for maintaining high recombination.

J. MAYNARD SMITH

An unconventional balance with an extra measure of accuracy

Mettler DeltaRange breaks through the boundaries that used to restrict the capacity/accuracy ratios of conventional weighing instruments. And Mettler PC electronic top-loading balances are equipped with this new *Mettler DeltaRange* feature.

Just press the control bar of the Mettler PC4400, for example, and you get a 400 g fine range with readings that are 10 times as accurate as those in the coarse range. And you can do it as often as you wish, at any point of the entire weighing range. That is to say, whenever and wherever a 0.01 g readability is needed. On a balance that has a capacity of no less than 4000 g!

In practice, this means that you can use a heavy container to accurately weigh in as many components as you want. Or that you can weigh one time on a lightweight paper, the next time into a heavy recipient; both times with results that are readable to the second decimal place.

To learn more about the many things your Mettler PC balance can do for you with outstanding speed and precision, send for our detailed brochure. It's an eye-opener.

INTERNATIONAL JOURNAL OF INVERTEBRATE REPRODUCTION

Editor-in-Chief:
K.G. ADIYODI. Department of Zoology, Calicut University, Kerala 673635, India
Associate Editors: K.G. DAVEY, Department of Biology, York University Faculty of Science, 4700 Keele Street, Downsview, Ontario M3JIP3, Canada.
K.C. HIGHNAM, Department of Zoology, University of Sheffield, Sheffield, U.K.

Aims and Scope

The International Journal of Invertebrate Reproduction will be devoted to the rapid publication of complete papers and short communications in the following fields of sexual, reproductive and developmental (embryonic and postembryonic) biology of the Invertebrata (excluding the Protozoa). The journal will publish only papers of high scientific quality and originality, shedding new light on fundamental principles and processes. In addition, it will provide the means for better communication between researchers by the publication of penetrating and provocative minireviews, announcements, reports of meetings, news and views, notices, and book reviews.

The quality of the journal is reflected in the following list of papers included in the first issue:

R.P. Ruegg and K.G. Davey *(Canada)* The effect of C18 juvenile hormone and Altosid on the efficiency of egg production in *Rhodnius prolixus.*

D.J. Wildish *(U.K.)* Reproductive consequences of the terrestrial habit in *Orchestria* (Crustacea: Amphipoda).

D.F. Went *(Switzerland)* Pathogenesis in the dipteran insect *Heteropeza pygmaea):* an interpretation.

Uma and T. Subramoniam *(India)* Histochemical characteristics of spermatophore layers of *Scylla serrata* (Forskal) (Decapoda: Portunidae).

M. de Jong-Brink, J.P. ter Borg, M.J.M. Bergamin-Sassen and H.H. Boer *(The Netherlands)* Histology and histochemistry of the reproductive tracts of the pulmonate snail, *Bulinus truncatus,* with observations on the effects of castration on its growth and histology.

1979 Volume I in 6 Issues

Founders of X-ray analysis

M. F. Perutz

William Henry Bragg, 1862–1942: Man and Scientist. By G. M. Caroe. (Cambridge University Press: Cambridge and London, 1978.) £8.95.

W. H. Bragg became famous for his early work on alpha rays, for founding X-ray crystallography together with his son W. L. Bragg, and as a superb expositor of science. This book by his daughter is an affectionate memoir, vividly written, and illustrated with pictures and quotations. It has some of the lightness of touch of Gwen Raverat's *Period Piece* which conjured up the lives of the Darwins. I only just knew W. H. Bragg as a benign and dignified looking old gentleman, but I worked with his son W. L. Bragg while he was Cavendish Professor of Physics at Cambridge from 1939 to 1953 and remained associated with him until his death in 1971. Mrs Caroe's sensitive portrait told me much about her father that also illuminates the son. The book will interest many people: physicists and crystallographers, historians of science, those concerned with the social role of science, with science education, with the relationships between science and government, and between science and religion.

W. H. Bragg was the son of a merchant seaman turned farmer in West Cumberland. He won an exhibition to Trinity College, Cambridge, read mathematics and finished 3rd wrangler. One day in 1885 he walked along King's Parade with J. J. Thomson, another Trinity man with whom he often played tennis. Thomson asked whether the senior wrangler had applied for the chair in mathematics and physics at Adelaide Bragg said, "No" and wondered if he himself might stand a chance. Thomson encouraged him to apply. The appointments committee consisted of J. J., of Horace Lamb, the mathematician who had just left the chair, and of the Agent-General for South Australia. The only other candidate could not be trusted with the bottle, and so they settled for the 23-year-old Bragg who abstained from drink. Happy days!

And more to come. Young Bragg had been brought up to work and no play, and had been poor, shy and lonely at Cambridge. He blossomed out in sunny Adelaide where he enjoyed the princely salary of £800 a year and did not feel his humble origins as a social handicap. He threw his energy into work for the new University and community, married the daughter of the Government Astronomer, and became much liked and respected. The Australian setting with its pioneering enthusiasm, its outings and easygoing social life is charmingly described, as when Mrs Caroe tells us that her grandmother would try to keep her grandfather at home before parties lest he invited everyone he met in the street.

It never occurred to Bragg to do any research until, aged 42, he had to address the Australian Association for the Advancement of Science. He chose the ionisation of gases. In preparing his lecture he came across a puzzling observation by Madame Curie which showed that alpha rays were not subject to an exponential absorption law, like other radiations, but penetrated a certain distance and then suddenly stopped, like bullets shot into a piece of wood. Bragg argued that they could not be colliding with other atoms but must be passing right through them, losing energy only by the ionisation they caused on the way.

Bragg procured some radium, built an ionisation chamber and soon proved his point. He sent his first paper to Rutherford at McGill for comment and waited an interminable 3 months for a reply. When Rutherford congratulated him:

> "I think you have struck the right explanation of the absorption of alpha rays and that it is merely a matter of careful experiments along the lines you are following to disentangle it completely."

Bragg replied:

> "It is very jolly to have your comments on my paper."

This was the start of a regular and very interesting correspondence, much of which is quoted. Bragg next discovered that his preparation shot out alpha particles of four different ranges, corresponding to the four different active substances that Rutherford had shown to exist, and that the particles of shortest range came from radium itself.

Bragg then turned to gamma rays, and Mrs Caroe describes how their exploration and that of the related X-rays sent him off on a wrong tack. How could cathode rays impinging upon a target produce X-rays and these same X-rays, on hitting another target, produce secondary cathode rays? If they were electromagnetic pulses, as Stokes had suggested, then why were these secondary electrons shot out mainly in the forward direction instead of parallel to the transversely vibrating field? And why were gamma rays and X-rays themselves scattered most in the forward direction instead of uniformly in all directions?

In 1907 Bragg wrote to Rutherford:

> "I have got the decisive experimental proof that gamma rays are not pulses, but corpuscular."

In a later lecture he said:

> "The Röntgen ray must move in a straight line without loss by the way, so that when it strikes the fatal atom it may have an undiminished amount of energy to give to the electron which takes its place, and the velocity of the latter may not depend on the distance the ray has travelled from the tube . . . We must replace our spreading waves by clouds of minute bundles of energy, tiny entities which move like material particles, but with the speed of light. It is a curious return in the direction of the old Newtonian corpuscular hypothesis."

He suggests that the electron, as it is driven against the anticathode, picks up a neutralising amount of positive charge, producing a neutral pair incapable of deflection by fields.

> "The neutralising positive may be torn away again from the electron in some other transit across an atom, and the Röntgen ray became once more a cathode particle."

Rutherford was enthusiastic at first, but later wrote more cautiously:

> "I quite appreciate the utility of the physical conception in your doublet, but I would at any time be prepared to consider it a bundle of concentrated energy which has all the properties of your doublet."

Some of Bragg's difficulties would have been resolved if he had studied Einstein's 1905 paper on the photoelectric effect, but in a letter to Rutherford at the end of 1911 Bragg admits that he had not heard of Einstein when he formulated his theory. In another letter he comforts himself with what must have been a garbled message:

> "Lindemann says that Planck's theory now is that the atoms can take in energy of any wavelength *at any rate*, but can only give it out in definite amounts—relativity is rather in the background in Berlin just now."

I found this account fascinating.

In 1909 Bragg's half-dozen papers on ionising radiations brought him an FRS and the physics chair at Leeds. Happy days! the reader may think again, but in fact it was the end of the happy days. While students and public at Adelaide had lapped up Bragg's vivid lectures, they fell flat among the sober Yorkshiremen. Mrs Bragg could not get used to the dirt, the smoky dark, the poverty and the rickety children of Leeds, and Bragg's neutral pair theory ran into stormy seas. Yet amidst the acrimonious controversy with Barcla his greatness shows. He does not withdraw into cynicism, but writes to Rutherford:

> "Supposing the identity of X-rays and light to be established, the supposition is this, I take it: The energy travels from point to point like a corpuscle: the disposition of the lines of travel is governed by wave theory. Seems pretty hard to explain: but that is surely, how it stands at present."

Mrs Caroe's quotations from Bragg's early papers and lectures already show his talent for expressing science in lucid, homely language free from jargon.

Meanwhile Bragg's son, William Lawrence, having graduated in mathematics at Adelaide at 18, became an undergraduate once more at Cambridge, reading mathematics and physics. He writes:

> "Dear Dad, I'm so glad you liked the notes on Jeans. I got an awful lot from a Dane who had seen me asking Jeans questions. He was awfully sound, and most interesting, his name was Böhr or something that sounds like it."

At Leeds in the summer holidays of 1912 he found his father intensely excited about the paper by von Laue, Friedrich and Knipping on the diffraction of X-rays by crystals. Back in Cambridge, he writes to his father:

> "I want to have a good go at this crystal divining . . . But don't let on for a bit till I can try the crystal Pope (the Professor of Chemistry) is getting for me."

Later:

> "I have just got a lovely series of reflections of the rays in mica plates with only a few minutes' exposure! Huge joy."

And the father writes:

> "My dear Rutherford, my boy has been getting beautiful X-ray reflections from mica sheet just as simple as the reflections of light in a mirror,"

but in Cambridge the son was teased for having disproved his father's corpuscular theory of X-rays. The discovery of Bragg's law, the interpretation of the Germans' diffraction patterns and the determination of the structure of common salt were all done by the son alone at Cambridge.

In Leeds meanwhile the father put his experience with ionisation chambers to good use in constructing an X-ray spectrometer, with which father and son solved the structure of diamond and other simple crystals. Together they founded the science of X-ray analysis; the world reacted thoughtlessly, as though the decisive advance had been made by the father, helped along by the son. The father made matters worse by referring in a literally patronising way, to his "boy's" work, when the "boy" was craving for recognition as an independent scientist. So their great discoveries, which brought them the Nobel Prize for Physics in 1915, tragically strained relationships between them for the rest of their lives. In his many lectures on the development of X-ray analysis W. L. Bragg was fond of defining the exact roles played by himself and his father, but he never hinted at those strains until a few days before his death when he wrote to me:

> "I hope that there are many things your son is tremendously good at which you can't do at all, because that is the best foundation for a father–son relationship"

—a reflection on the painful competition between himself and his father. Mrs Caroe alludes to the conflicts between them with affection and sympathy for both.

W. L. Bragg with his father, shortly before the latter's death in 1942

In 1923 Bragg father became Director of the Royal Institution where he remained until his death 19 years later. Here he founded a flourishing school of X-ray crystallography from which much of today's biological structure analysis is descended. He also found scope for his superb gifts of popularising science, especially to children, and became a protagonist of the role that science ought to play in education, government and industry. He wanted children to learn more science, but opposed a purely scientific education that turns out backroom boys.

> "'If research workers' education were made more general, they would move into the Councils of industry to which specialists in science are as yet rarely admitted. The scientific expert must himself take down the barricade that makes the alley blind."

To this end he admonished scientists to make themselves understood:

> "We cannot compel men to make use of science in the right way, but the chance that good use will be made is in a curious way dependent on the ease with which it is stated."

Unlike Monod in *Chance and Necessity*, who tries to base a new ethics on scientific truth, Bragg thought science was neutral:

> "Science is merely knowledge. It has no morality at all. The achievements of scientists have value of one kind, and the spirit in which they worked has value of another kind. Faraday's reverence for truth and unselfish devotion to its acquisition have a higher value than the laws which he established."

Perhaps this is what Monod meant. Bragg regarded science as an ever receding frontier.

> "There is a hesitation which would beg us not to push forward lest we come to think less of the world. As against this, research is an act of faith in the immensity of things. There is no end to the search: it is a poor thought that there might be." "The work of discovery will go on and no one can stop it."

Who would dare to say this today?

In his last year at school Bragg went through a harrowing religious experience, reminiscent of the one described so movingly in James Joyce's *Portrait of the Artist as a Young Man.* A less level-headed person might have reacted by turning against religion, but Bragg tried to bring religion into harmony with science, because he had faith in both,

> "From religion comes a man's purpose; from science his power to achieve it. Sometimes people ask if science and religion are not opposed to one another. They are: in the sense that the thumb and fingers of my hand are opposed to one another. It is an opposition by means of which anything can be grasped."

His daughter writes of him:

> "Religious faith to him was the willingness to stake his all on the hypothesis that Christ was right and test it by a lifetime's experiment in charity."

His charity found expression in the help he gave to Jewish scientists when they were driven from Europe by the Nazis, and again when they were misguidedly interned here as potential spies during the Second World War. In general, Bragg spoke only of the benefits that science would bring, but once he wrote:

> "If it falls into the hands of evil persons working for evil ends we, as scientists, can do nothing about it."

I am surprised that he should have taken that easy line, perhaps because he was spared the heart-searching in the aftermath of Hiroshima.

Rutherford, another farmer's son, regarded Bragg "as a very great man", but Bragg himself remained diffident about the qualities that had raised him to the Presidency of the Royal Society. One evening, opening his study door, his daughter noticed how wearily he looked up from his papers.

> "Daddy, need you work so hard?"

she cried, and he answered simply,

> "I must dear; I'm always afraid they'll find out how little I know."

Bragg's last scientific function was a radio discussion with Bernal on living

Announcing a Major New Journal

Immunology Letters

CALL FOR PAPERS

for the rapid publication of short reports
in Immunology

Published by Elsevier/North-Holland in association with the Federation of European Immunological Societies (I.U.I.S.).

Aims and Scope
The journal will provide a vehicle for the rapid publication of short, complete and definitive reports of work in all aspects of immunology. The essential criteria for publication will be clarity, experimental soundness and novelty. Results contradictory to current accepted thinking or ideas diverging from actual dogmas will be considered for publication provided that they are based on solid experimental findings. Preference will be given to papers of immediate importance to other investigators, either by their new methodology, experimental data or new ideas. Commentaries and replies related to the published reports may also be accepted provided that they are short (maximum 700 words) and scientifically relevant to the reports mentioned, in order to provide a continuing forum for discussion.

EDITORIAL BOARD: **J.F. Bach.** *(France).* ASSISTANT MANAGING EDITOR, **G. Bordenave,** *(France).* MANAGING EDITOR, **A. Bussard** *(France).* **F. Celada** *(Italy).* **B. Cinader** *(Canada).* **A.J.S. Davies** *(England).* **V.P. Eijsvoogel** *(The Netherlands).* **F. Franek** *(Tchecoslovakia).* **J. Gergely** *(Hungary).* **J.C. Howard** *(England).* **H. Isliker** *(Switzerland).* **B.D. Jankovic** *(Yugoslavia).* **F. Karush** *(U.S.A.).* **P. Krammer** *(F.R.G.).* **J. Lisowski** *(Poland).* **P. Lydard** *(England).* **O. Makela** *(Finland).* **H. Muller-Eberhard** *(U.S.A.).* **R. Nezlin** *(U.S.S.R.).* **G.J.V. Nossal** *(Australia).* **M. Rose** *(England).* ***C. Steffen** *(Austria).* **T. Tada** *(Japan).* **J. Urbain** *(Belgium).* **H. Wagner** *(F.R.G.).* **A.L. De Weck** *(Switzerland).*

* All "letters to the Editor" should be directed to Professor C. Steffen.

AN AUDIOVISUAL

GUIDE TO SEARCHING THE BIOLOGICAL LITERATURE

Michael M. King, Ph.D.
Linda S. King, M.L.S.

Five important references are discussed:

EXCERPTA MEDICA
INDEX MEDICUS
BIOLOGICAL ABSTRACTS
(including BIO RESEARCH INDEX)
CHEMICAL ABSTRACTS
SCIENCE CITATION INDEX

The structure of each tool is skillfully examined with the aid of a common search topic. This not only enhances comprehension by emphasizing the practical aspects of literature searching but serves to highlight relative strengths as well. The program was developed for students and practicing professionals in the life sciences, biology, medicine and related fields and is suitable for both group presentation and auto-tutorial study.

Materials consist of a set of 78 visuals in 35 mm slide format, 2 audio cassettes, approximately 90 minutes in total length, and text. Price: $165.00.

Orders may be placed directly with Science Media, P.O. Box 910G, Boca Raton, FL 33432 USA. (Outside USA add $15.00 to your order for air mail postage and handling. Remittance must accompany your order. Return privileges honored)

Circle No. 08 on Reader Enquiry Card.

NICHOLAS COPERNICUS

VOLUME II ON THE REVOLUTIONS

AN ENGLISH TRANSLATION BY EDWARD ROSEN

It is nearly 500 years since Nicholas Copernicus, the father of modern physics, dedicated to His Holiness Pope Paul III, his theories on physics in De Revolutionibus Orbium Coelestium.

Now for the modern academic, unversed in mediaeval Latin, Professor Rosen has produced a new translation, together with a detailed commentary on the complete Latin text.

This is the 2nd volume in a planned 3-volume set of the complete works of Copernicus organised by the Polish Academy of Sciences. Printed and bound to a very high standard, it is a work of great scholarship and art in its own right, and a fitting companion to Volume I, the full-colour facsimile edition published in 1972.
£35.00 0 333 14530 5

M MACMILLAN PRESS

crystals. It was all about the nature of proteins and viruses. Bragg:

> "How do protein molecules get folded? Can no one make a protein?"

Bernal:

> "It looks as if all proteins are made by others inside the cells."

Bragg:

> "But if one protein must always come from another, how did the first one get there?"

Bernal's answer avoids this paradox.

> "One big step towards finding out is getting the structure of proteins and viruses It's really the problem of the origin of life."

No inkling yet about the role of nucleic acids. Bernal had been Bragg's research student, and Bragg may have had him in mind when he wrote:

> "A good research student is like a fire which needs but a match to start it."

Quotations such as this one make the book delightful reading.

I was intrigued by the similarities between father and son. They had both read mathematics, but neither was a theoretician at heart, and they solved scientific puzzles in a concrete, visual fashion. The father complained of Planck not bothering to think about the physical nature of the quantum and to the son quarks had no appeal. To them a structure solved was like an artist's vision, to be described in words of poetic imagery. They felt more at ease with children than adults and preferred to deal with things rather than people. They were no match for politicians: the father was taken for a ride by the higher civil servants when he demanded that science should have a stronger voice in the conduct of the war; the son was helpless among the Byzantine complexities of University politics. The father's faith in God and the goodness of science marks him out as a man of the last century rather than of this one; the son avoided ultimate questions and tended his garden.

What would the reader gain from this book? Much enjoyment; the realisation that success in science can be combined with devotion to human values, and that occasionally the great can also be good and true ☐

M. F. Perutz is Chairman of the Governing Board of the MRC Laboratory of Molecular Biology, Cambridge, UK

DNA inconstancy

Endopolyploidy and Polyteny in Differentiation and Evolution. By W. Nagl. Pp. 283 (Elsevier/North-Holland: Amsterdam, New York and Oxford, 1978) $54 50; Dfl.125.

As indicated by its title, this book is concerned with the relationships between two of the central issues in biology—namely, differentiation and evolution The thread that connects the two, as seen by the author, is the occurrence of DNA variation as an important aspect of both Evolution has been accompanied by remarkable shifts in the amount, and in the organisation, of basic genomal DNA in different species Moreover, in very many Orders of animals and plants, there occurs varying degrees and types of ontogenetic elaboration of the basic genome These are seen in their most obvious expression as polyteny and endopolyploidy, and more subtly, as amplification of certain selected regions of the genome such as the ribosomal cistrons.

To many biologists, such expressions of DNA inconstancy are mere curiosities which, though useful experimentally, serve to emphasise the rule of DNA constancy, with normal mitosis as the orthodox mechanism of DNA growth. Reading this book will do much to redress the balance for, far from being the exception and the concern of insects and bugs, DNA inconstancy is to be found universally In fact, after reading this book one feels that the cell nucleus has such a penchant for ontogenetic elaboration that the problem becomes not how or why this occurs, which are matters discussed at length, but how species manage at all to maintain DNA constancy for the purposes of ensuring their continuation.

In all probability it is precisely the failure of species entirely to constrain the exuberance of DNA in this respect that is one of the main driving forces of the evolutionary process In a very real sense, therefore, the study of ontogenetic DNA variation contains valuable clues to the understanding of phylogenesis and evolution. In other words, speciation and differentiation are two sides of the same coin, which is DNA variation Along the way to making this point the book commences with a concise and up-to-date account of the organisation of the eukaryotic chromosome and continues with chapters dealing with the occurrence and characterisation of endopolyploid nuclei, the mechanism of endopolyploidisation, further mechanisms of DNA variation, control of endopolyploidisation and polytenisation, functional significance of endocycles, and, finally, evolutionary aspects.

This final chapter brings together the threads runing through the previous parts of the book in a far ranging discussion concerned with the meaning of DNA variation in evolution. Commencing with a tabulation of various mechanisms of, and the terminology for, DNA variation in phylogeny and ontogeny, the author discusses the role of point mutations (adaptation and anagenesis) and of repetitive DNA (speciation and cladogenesis) in the evolutionary process In particular he emphasises the nucleotypic effects of alterations in DNA and of genomal DNA repatterning as important mechanisms. Nucleotypic effects are considered to be explicable principally in terms of the Britten–Davidson model of gene regulation and the relationship of DNA interspersion patterns to genome size is discussed as a possible nucleotypic effect of DNA mass Endopolyploidisation and differential DNA replications are considered as evolutionary strategies in light of the fact that, in general, these phenomena achieve their most extreme expression in species with relatively low DNA C values.

The final paragraphs of this chapter set out the author's views concerning the integration of DNA variations during ontogenesis and evolution summarised by what he terms the DNA optimisation model. This illustrates some possible changes in genomal size and organisation during phylogenesis and considers their possible consequences on development This is altogether a very thought-provoking section of the book which is otherwise an extensive and important review.

Altogether there are 283 pages, of which 49 pages are of references, including the Russian and older German papers amounting in all to over 1200 references of which 55 are to the work of the author and his colleagues These are extensively cited and critically discussed and cross-referenced, making this not a book to be read without effort. It is well and profusely illustrated with line diagrams and half-tones, and contains many unique and informative tabulations of data collected from the numerous sources cited. There is a useful subject index and two appendices containing a glossary of terms and further guidance to the methodological literature dealing with the detection of endopolyploidy and differential DNA replication, the preparation and analysis of chromosomes, *in situ* hybridisation, DNA characterisation, and genome organisation analysis

An indispensible book for the expert but aimed also at a wider readership, it should appeal to students of cytogenetics and molecular biology.

K. W. Jones

K W Jones is Reader in the Institute of Animal Genetics, University of Edinburgh, UK.

s and
on

and Recognition. Series A. Vol. 5. Edited by P. Cuatrecasas and M. F. Greaves. Pp. 212. (Chapman and Hall: London, 1978.) Hardback £10; paperback £6.

PREVIOUS volumes in this series have contained four or five articles, but this one contains only three, albeit rather longer, contributions. "Relationships in the structure and function of receptors for glycoprotein hormones, bacterial toxins and interferon" by L. D. Kohn is a contribution central to the theme of the series, whereas "Stereoselective recognition in biology" by P. A. Lehmann and "Fluorescence and NMR studies of membranes" by A. G. Lee can be considered to some degree as contributions to the general education of those interested in biological recognition processes.

Lehmann's chapter is a wide-ranging discussion of the ways in which the mutual recognition between macromolecules and small ligands may be influenced by stereochemical variations in the nature of the bound ligand. It draws its examples from an extraordinary diversity of receptor and enzymic recognition systems, thus placing shoulder to shoulder the pheromones of bark beetles, the proteolytic specificity of papain, conformationally hindered thyroxine derivatives and the interaction between avidin and biotin. Not unnaturally, substantial space is given to the author's own 'eudismic' method for deriving quantitative relationships between affinity and stereoselectivity in various series of homologous pairs of stereoisomers

As there have recently been a considerable number of reviews of the contributions of spectroscopic techniques to understanding of membrane structure, some of them by Lee himself, a chapter on this topic would only seem justified if it emphasised the ways in which such techniques might be helpful to students of biological recognition phenomena. Unfortunately, this is not what is offered. Instead, the chapter opens with good intentions of interpreting NMR data for the uninitiated, but it soon becomes yet another detailed discussion of the spectroscopic characteristics of hydrated lipids, especially dipalmitoylphosphatidylcholine. Proteins, and even receptors, do get briefly discussed in the final section on fluorescence studies, but it seems doubtful whether many general readers will get this far.

Finally, Kohn's contribution takes us to the heart of recent studies on the receptors for a superficially diverse 'family' of ligands (glycoprotein hormones, bacterial toxins and interferon). It is mainly through the work of Kohn and his colleagues, particularly their studies on gangliosides as receptor components and on sequence homology, that these ligands and their receptors can in any sense be regarded as a family. Because of this, the chapter is to be welcomed, but with the slight suspicion that Kohn may, at least sometimes, be adept at seeing unities where none exist. As this is very much the chapter of an enthusiast, it is filled with intriguing snippets of unexplained new information which will keep the reader's appetite whetted for the next episodes in this intriguing tale.

Overall, therefore, this is an uneven book with too much space devoted to material far from the nitty-gritty of receptors and recognition. Its proofreading may be a bit better than in earlier volumes (see review in *Nature* **274**, 192–193; 1978) but there is still no index (purchasers of volume 6, as yet unpublished, are to get the indices of volumes 1–5 as a bonus). **R. H. Michell**

R. H. Michell is Lecturer in Biochemistry at the University of Birmingham, UK.

Conformational energy surfaces

Biomolecular Information Theory: Studies in Physical and Theoretical Chemistry. By S. Fraga, K. M. S. Saxena and M. Torres. Pp. 271. (Elsevier: Amsterdam, Oxford and New York, 1978.) $48.75; Dfl.112.

READING this book was a horrible experience. I hasten to add that this was not a fault of the book itself, which has many commendable features. It was merely a manifestation of that recurrent nightmare of text-book writers, a new book with similarities to that which he is in the throws of writing. After some deliberation, it seemed that it would be fun to review a book from an unusually informed viewpoint, but the reader of this review is forewarned that the reviewer may be revealing some of the prejudices of a literary cuckold.

Inevitably, closer inspection revealed many important differences. It is primarily an essay in quantum biochemistry, with emphasis on the conformational energy surfaces of units of protein and nucleic acid molecules. The title is, perhaps, somewhat misleading, as the book does not contain much more about biomolecular information than most biochemical and biophysical textbooks, and there is very little information theory proper. Nonetheless, the first major section provides an illuminating discussion of topics peripheral to an information theory of biological molecules, including the mathematics of the prebiotic origins of self-replicating systems. There is also an entertaining account of the formation of amino acids in the prebiotic soup, and of the occurrence of amino acids in meteorites and Moon dust.

The second major section is largely a vehicle for discussing the stereochemical code of proteins and nucleic acids in terms of the conformational behaviour of low molecular weight analogues of their units In particular, N-acetyl N′-methylamide derivatives of amino acids are considered and there is an exhaustive treatment of their conformational energy surfaces as a function of the two major angles of rotation in the backbone. There is also an extensive discussion of the theory and methods (with appendices) for calculating such energy surfaces, and of techniques (such as minimisation and Monte Carlo) for treating more complex energy surfaces. Unfortunately, the authors run the risk of placing too much emphasis on one type of energy calculation, the semi-empirical quantum mechanical PCILO technique of Maigret and Pullman. Indeed, much of the book reads like an encyclopaedia of PCILO results. This gives the text a certain consistency, but the danger of emphasising one type of calculation is that the future usefulness of the book depends to some extent on the validity of that calculation. It was a little one-sided of the authors to opt for PCILO, because the energy surfaces calculated by this method are somewhat anomalous with respect to those derived by the classical studies, as well as by recent empirical crystal-derived potentials and extended basis set *ab initio* calculations. Some CNDO results are reported, although this is one of the few types of calculation which produces similar energy surfaces to PCILO. The consequence of this is that the stereochemical code as viewed by the authors well allows some conformational features not believed by many workers.

Incidentally, the energy maps are presented in the old angle convention, which might cause some confusion in the partially initiated, particularly as the old convention is not used consistently throughout the book.

More generally, the book is pleasant to read, although the jargon is not well suited to biologists. Its mood is technical rather than journalistic ("Valinomycin is a cyclodecadepsipeptide") A few sections, such as that on "Topological Characteristics of Energy Hypersurfaces", turned out to be more trivial than suggested by a first read.

'It is a book of its time not only in content and outlook but in format and style too . . . . could well become a milestone in the development of textbooks of physical chemistry.' *Chemistry in Britain.* 'An important and original work.' *Education in Chemistry.* 'The author is to be congratulated on the production of such a good text and the publishers for its presentation at a price within the reach of students.' *British Book News.* £15 paper covers £7.95

Primary Metabolism

A Mechanistic Approach

J. Staunton

The traditional line of demarcation between biochemistry and chemistry has dissolved in recent years as chemists and biochemists have joined forces in investigating the mechanisms of reactions which take place in living systems. This book introduces this area of common interest to students of both chemistry and biochemistry. £6.50 *Oxford Chemistry Series 29*

Secondary Metabolism

J. Mann

'It is encouraging to see published a book such as Dr Mann's, which is designed for the undergraduate and beginning researcher. His book is very well put together and should facilitate and encourage the preparation of undergraduate courses on modern natural products chemistry.' *Chemistry in Britain.* £9.75 *Oxford Chemistry Series 27*

Numerical Solution of Partial Differential Equations

G. D. Smith

This substantially revised second edition covers linear and non-linear parabolic equations, the analysis of errors, first- and second-order hyperbolic equations, elliptic boundary-value problems, systematic iterative methods, consistent orderings of matrices, and recent methods for large linear systems. Second edition illustrated £9 paper covers £4.95 *Oxford Applied Mathematics and Computing Science Series*

The Bowels of the Earth

John Elder

This paperback reprint has replaced the boards edition which was published in 1976. 'Original, persuasive, intensely individual . . . . the book is plainly a *tour de force,* and it may set a new model for scientific exposition . . . . The prose . . . . is direct and evocative.' *Scientific American.* Paper covers £2.95

Human Growth and Development

Wolfson College Lectures 1976

Edited by Jerome S. Bruner and Alison Garton

These papers explore some of the biological, social, and political factors involved in growing up in modern society. They indicate the strong admixture of biological and social determinants that influence behaviour during child development, and two main themes run through the book: the importance of achieving social connection, and the active nature of childhood. £4.25 paper covers £2.25

Mechanics and Motion

L. Mackinnon

This book, based on the first-year course given by the author at the University of Essex, provides a survey of those topics that are an essential background to modern physics and advanced engineering. Throughout, the emphasis is on the basic physical concepts necessary to a study of the more advanced courses that will follow. £6 paper covers £3.25 *Oxford Physics Series 17*

The Properties of Nuclei

G. A. Jones

This book describes the properties of nuclear levels, starting with stable states and progressing, via quasi-stable states (radio-active ground states and nuclear-stable excited states), to unstable (nucleon-emitting) states. The shell model, the collective models, and the optical model of the nucleus are described, and nuclear reactions are introduced in terms of the compound nucleus and direct processes. £5.95 *Oxford Physics Series 12*

Circle No. 17 on Reader Enquiry Card.

Some of the mathematical treatments also seemed complicated even to workers in this laboratory who had previously translated equivalent treatments into working computer programmes, although it must be admitted that there are many books which are much worse in this respect. The book seems rightly aimed at theoretical chemists, intending to introduce them to the biological applications and significance of their work.

In the last analysis, it is a book I would be glad to own.

Barry Robson

Barry Robson is Lecturer in Biochemistry at the University of Manchester, UK.

Electrical properties of biological cells

Impedance Measurements in Biological Cells. By O. F. Schanne and E. R. P.-Ceretti. Pp. 430. (Wiley-Interscience: New York and Chichester, UK, 1978.) £21.20.

THERE exist two major schools of thought about the measurement of the electrical properties of biological cells One owes its origin to a physicomathematical approach using the concept of impedance. Typically, this involves investigating the response of the cell to a wide range of frequencies followed by an attempt to model the response physically with an electrical equivalent circuit. The second school has typically been more interested in measuring the membrane resistance and in relating this to the physicochemical mechanisms determining the membrane permeability to ions. This has usually involved measuring the response to step changes of potential or current. Of course, the two approaches are complementary but it is nevertheless true to say that in the past the two schools have sometimes been far apart; even when they have come together on the same problem the interpretations have retained characteristic differences. I myself think that this is exemplified by the major difference between the approaches of Cole and of Hodgkin and Huxley to the analysis of the squid nerve fibre. The same properties of the cell lead Cole to represent the cell as behaving like an inductance, whereas Hodgkin and Huxley represented the inductance by a time dependent permeability change A trivial difference in one sense, as the representations are equivalent. A major difference from an heuristic viewpoint since one's choice of representation does determine what one thinks is worth doing in future experimentation.

The authors of this book are well aware of this difference of approach; indeed they refer to the need to "show that the results obtained by the two groups complement each other". The book begins with a valuable treatment of the experimental and theoretical methods employed. This is followed by sections on impedance measurements in nerves, in muscles, in epithelia and on cell suspensions. In the process, a vast amount of an even vaster literature is reviewed. My major criticism of the book is that the attempt to show that the results obtained by the two groups complement each other is not very well sustained. Many parts of the later chapters are simply reviews written largely in terms of the outlook of the original authors. My second criticism is that this review of the literature does not extend much beyond 1972 in many chapters.

Anyone who has written a book of this size and extent will readily understand the problems but, whether these are primarily those of the authors or publishers, the reader should be warned that he cannot expect the treatment of certain areas to be very up-to-date. There are many examples of this. Thus, in the section on passive properties of cardiac muscle, the important work of Mobley and Page in 1972 is included, but the equally important contribution of Hellam and Studt in 1974 is omitted. In the section on skeletal muscle, Costantin's work up to 1970 is included but not his 1973 work with Taylor, nor his valuable 1975 review. I cannot therefore imagine that many private buyers will find the book sufficiently useful to justify buying it, but as a library volume for reference purposes, it may still be worth considering.

Denis Noble is a Fellow of Balliol College, Oxford, UK.

Techniques of centrifugation

Centrifugal Separations in Molecular and Cell Biology. Edited by G. D. Birnie and D. Rickwood. Pp.327. (Butterworths: London and Boston, 1978.) £14; $28

THIS book is concerned mainly with work that is done using preparative rotors. It proceeds from the theoretical background to consider in turn rate-zonal centrifugation, separations in zonal rotors, and isopycnic centrifugation.

The main chapter on theory acknowledges the antipathy of some biologists towards mathematics by relegating some sections to an appendix. In other chapters considerable use is made of simplified equations to illustrate principles, and even those who have not followed the derivations are encouraged to avail themselves of the resultant expressions much as they might do the time shown on an electronic watch. The design of their experiments, often an art as much as a science, may thereby be improved. Those practitioners who feel, for financial or other reasons, that their machines ought to have a shorter working week and higher payload, may benefit substantially from such considerations. Theory properly applied enables extra information, such as sedimentation coefficients, to be obtained from preparative experiments, but the authors wisely include a caution about the importance and sometimes difficulty of maintaining adequate temperature control.

The chapter on isopycnic systems emphasises the advantages of fixed angle rotors. Although it mentions lipoproteins specifically, it fails to draw attention to the satisfactory separations of glycoproteins that have been achieved with this technique. Ancillary equipment receives some attention, but the survey of types of gradient-forming devices does not mention the versatile apparatus of Hegenauer *et al.* The percipient reader will notice a few blemishes, but these are rarely misleading. In chapter 2, η is used in the conventional way for viscosity, but in later chapters symbolises refractive index. Equations 6 7 and 6.8 were first derived by Ifft *et al.* in 1961, not 1970. In chapter 8 in several places the "e" is omitted from "Weiss". The most intriguing observation is "esosteric" on p189, a term that invites adoption by anyone who can muster a credible claim. Though the chapter on analytical ultracentrifugation is strictly within the scope of the title of the book, readers interested in these matters will probably seek a more specialised text. Where repetition occurs, its objective seems to be to make each chapter fairly self-contained.

This volume is well-written, is full of practical tips, and has concentrated from diverse sources a collection of tables on the characteristics of many types of biological particles, macromolecules, gradient materials, rotors and tubes. It will afford something of value to even the most experienced worker.

P. A. Charlwood

P. A. Charlwood is on the scientific staff of the MRC at the National Institute for Medical Research, London, UK.

Nutritional problems of the Third World

Development, Reform, and Malnutrition in Chile. By P. Hakim and G. Solimano. Pp. 91. (MIT Press: Cambridge, Massachusetts, and London, 1978.) $10; £7.

THERE is a real need for examples of national programmes that actually work within the economic restraints of developing countries Development should benefit people, and the best measure of an improved quality of life is the elimination of malnutrition, which results pimarily from poverty and ignorance. It is not enough to increase food production when people cannot buy it, nor to raise incomes when people do not know what to buy. The Chilean example has much to commend it, as an attempt was made to reduce malnutrition at a time of social change The Allende régime lasted three short years, but during this period it attempted fundamental changes in economic policy by bringing large sections of industry under state ownership and extending land reform. A general redistribution of income was achieved, unemployment was reduced, and the social services were made more available to the low income groups. Food consumption increased by about 10%, although largely as a result of food imports, and the distribution of free milk by the Government was trebled In other words all the elements for the successful improvement of nutritional status appeared to be present. The question is, did it happen?

The authors of this book are frankly pessimistic, although a proper evaluation was not carried out. The free milk scheme, the major topic of their book, provided distribution from schools and clinics which were not available to all the population thereby giving preference to the richer urban community: the milk reached only 70% of the eligible beneficiaries. Although it was provided to the most vulnerable age groups, it was often shared within the family and occasionally sold. Nevertheless, 40,000 tonnes of dried milk was distributed annually. A careful analysis of Chile's nutritional problems reveals, however, that they are due to a low consumption of food rather than a lack of particular nutrients and the emphasis on protein should be challenged.

It is self-evident that the primary need of starving children is food In retrospect, the authors recognise the lack of scientific rationale for the milk programme and admit that the present oppressive government, which is now distributing 25,000 tonnes but with added fat, might be better advised. The promotion of protein-rich foods derives from old-fashioned nutritonal ideas which were outmoded at the time of Allende, and that of free milk from socio-political targets which were unrealistic for the economy. All of this is examined in detail in the book.

It could be argued that the period was too short to expect any change in nutritional status, but this is not so. The growth rate of deprived children shows a marked improvement when they are well fed: a nutritional programme in Korea has led over seven years to a national increase of 3 cm in average height and 1 kg in average weight of children Also, in Ethiopia an applied nutritional programme halved the infant mortality rate in three years. Simple statistics of this kind are essential for evaluation—relatively easy to obtain, but not apparently available from Chile over the relevant period. Such data may not be as easy to interpret as the results of laboratory experiments where everything is controlled, but it is more satisfying to try to explain successes than failures.

The authors are well aware of the economic, educational and medical factors influencing nutritional status and suggest that all were improving during Allende's time but the reader, may not be entirely convinced. In particular, although they distinguish between preventative and curative medicine, they do not stress the difference between the strictly medical and public health engineering, for example, water and sanitation The latter is probably more effective than vaccination programmes albeit much more expensive. Similarly the educational programmes were largely through the mass media and possibly did not reach or convince the most socially deprived. Finally, action to redistribute wealth which satisfied the intellectuals, may not have been as effective as claimed. But certainly the position has deteriorated since 1973 and the brave efforts of Allende reported here are worthy of this objective documentation.

The book will interest those concerned with recent Chilean history, but will be most valuable to those grappling with nutritional problems of the Third World.

Chemical and enzymic catalysis

Transition States of Biochemical Processes. Edited by R. D. Gandour and R L Schowen. Pp.616. (Plenum: New York and London, 1978.)

THE theory of absolute reaction rates, commonly known as transition state theory has been perhaps the most influential principle in the development of our knowledge of reaction mechanisms in solution. This book consists of a series of chapters written by 21 authors on the theories and methods used to investigate chemical and enzymic catalysis

The book is written in four parts. In part I the assumptions in transition state theory are examined and its application to chemical kinetics and mechanisms discussed. When enzyme-catalysed reactions are considered, the fundamentalist view is adopted, namely that catalysis originates from stabilisation of the transition state through binding to the catalyst.

In part II, which is the longest section of the volume, the main techniques used to investigate transition state structure and properties are introduced. Rightly this section is dominated by the application of isotope effects. Primary, secondary and solvent isotope effects of hydrogen are discussed as well as the heavy-atom isotope effects on carbon, nitrogen, oxygen and chlorine The first chapter of this section, however, introduces the quantum mechanical procedures which have been used to investigate enzymic transition states and reaction pathways. The last two chapters review the application of magnetic resonance techniques to investigate enzyme–ligand complexes and the mapping of reaction pathways from X-ray crytallographic data

In part III, well studied reactions are discussed which are biochemically important These include acyl, methyl, and phosphoryl transfer, acetal hydrolysis, decarboxylations and relevant models of enzymic reactions In the final part, the use of inhibitors as tools to elucidate the sources of enzymic catalysis are discussed and the application of transition state information to the design of potent drugs is described.

Thus the book ranges over all the major disciplines which have contributed to the investigation of chemical and enzymic mechanisms The editors have selected an excellent array of authors and have welded their contributions together into a text which will be of value to a wide range of chemists and biochemists.

Aims and Scope

The journal will be primarily concerned with the publication of ethological and sociobiological data and theories presented as descriptive studies, experiments, literature reviews, or in papers dealing with theory development and refinement. As the primary focus of the journal is on the human species, the aim is to foster the dissemination of scientific knowledge in ethology, sociobiology and closely related fields, particularly as this knowledge applies to humans. Findings and theories largely concerned with nonhuman species will be acceptable to the journal provided the human implications are specified.

ES HOUCHES Summer School 1979

2–28 July

PHYSICAL COSMOLOGY

Physics and evolution of the universe as a whole

Cosmological models confronted with observations — J. LEQUEUX — *Observatoire de Paris - Meudon.*

The early universe. I. D. NOVIKOV, *Academy of Sciences, University of Moscow.*

Formation and evolution of galaxies and clusters of galaxies — J. E. GUNN, *California Institute of Technology.*

Masses of galaxies and clusters of galaxies — P. J. E. PEEBLES, *Princeton.*

The observational cosmological parameters — G. TAMMANN, *Université de Bâle.*

Quasistella objects; radiogalaxies and interstella matter — M. REES, *Institute of Astronomy, Cambridge* and M. LONGAIR, *Mullard Observatory, Cambridge.*

There will be an additional programme of seminars on theoretical and observational topics. The lectures will start from a basic level and will progress to the recent advances in physical cosmology. Emphasis will be put on the observational and physical grounds of cosmology.

Astrophysicists interested in observational or theoretical cosmology, as well as physicists working on related topics are welcome to apply. About 50 participants will be chosen by a committee meeting in early March 1979. Scientific organisers are J. Audouze and D. N. Schramm.

30 July–30 August

BIOPHYSICS of MEMBRANES and INTERCELLULAR COMMUNICATION

This session will review the present knowledge on the molecular organisation of the cell membrane and the mechanisms of intercellular recognition and information transfer at the extracellular level. The analysis in terms of molecular structure and physico-chemical interaction will be emphasised. Particular attention will be paid to the common molecular aspects of the various biological fields concerned. Extended and progressive series of lectures will cover:

The cell membrane — S. J. SINGER, La Jolla.
Structure and dynamics of membrane components: Proteins — M. KARPLUS, M.I.T. and R. HENDERSON, M.R.C. Cambridge. Lipids — J. SEELIG, Basel. Carbohydrates — N. SHARON, Rehovoth.
Lateral motion in membranes — H. M. McCONNELL, Stanford.
Channels and ionophores in artificial membranes — P. LAUCER, Konstanz.
Excitable membranes — C. BERGMAN, Paris and H. MEVES, Plymouth.
Synaptic transmission — P. ASCHER, Paris and J. P. CHANGEUX, Paris.
Hormonal receptors and intramembranous transduction — S. JARD, Paris and M. RODBELL, Bethesda.
Immunological recognition — M FOUGEREAU, Marseille and J. F. A. P. MILLER, Melbourne.

Other lecturers will give short courses on related topics. Scientific organisers are Marc Chabre, Grenoble, and Philippe F. Devaux, Paris.

The school is intended for young biologists involved in one of the domains treated, and willing to broaden their knowledge and to study the more fundamental aspects; they should have a good understanding of modern physical and chemical methods. The courses will also interest physicists or chemists wishing to orient towards this type of biological problems, and possessing already a basic knowledge of molecular biology and biochemistry.

Established in 1951, the school occupies a group of mountain chalets surrounded by meadows and woods, in the French Alps near Chamonix and facing Mont Blanc. The location offers mountain climbing, hiking and touring opportunities, and is favourable for intellectual work. Accommodation and meals are provided in the school for both participants and lecturers.

Since 1958, the proceedings of the Summer School of Les Houches are edited as a series of volumes (North-Holland, publisher), which cover pedagogically all branches of physics.

Two sessions will take place in 1980, one on Defects in materials, the other on Physics of laser-plasma interaction.

The Summer School of Les Houches is an institute affiliated with the Grenoble University. The 1979 sessions receive support from the Advanced Study Institutes Programme of NATO.

APPLICATIONS

Additional information and application forms may be obtained from: *Ecole d'Eté de Physique Théorique, 74310, Les Houches, France, tel. (50) 54 4133.* Posters available upon request.

DEADLINE

APPLICATIONS AND LETTERS OF RECOMMENDATION MUST HAVE REACHED THE SCHOOL BY *March, 1979.*

Circle No 13 on Reader Enquiry Card

Awards

Guido Brunner, Commissioner of the European Community responsible for energy policy, has been awarded this year's Melchett Medal of the Institute of Fuel. The award is made annually "for outstanding work, whether in research, administration, construction, or other professional activity involving the scientific preparation or use of fuel, the results of which have recently been made available for the benefit of the community".

Dr David Arthur Davies, Secretary-General, World Meteorological Organization, has been awarded the Gold Medal of Merit of the Czechoslovak Academy of Sciences, Prague.

The 1977 Kalinga Prize has been awarded by a UNESCO international jury to **Fernand Seguin** in recognition of his life's work in popularising science.

Nominations are invited for the 5th Marconi International Fellowship Award. The Fellowship aims to commission creative scientific works that will add to knowledge and understanding of how communications sciences and technologies can be applied to improvement of human life. Contact Walter Orr Roberts, 1919 Fourteenth St, No. 811, Boulder, Colorado 80302.

The Council of the Royal Society are inviting nominations for the 1979 Royal Society Esso Award for the Conservation of Energy which should be sent to R. W. J. Keay, The Royal Society, 6 Carlton House Terrace, London SW1, UK, by 6 February 1979. The award is for outstanding contributions to the advance of science or engineering or technology leading to the more efficient conversion or use of any form of energy, and consists of a gold medal and a prize of £1,000.

The World Phosphate Rock Institute has created the Imphos Award to extend the impact of the First International Congress on Phosphorus Compounds and to foster research on their non-fertiliser uses. The first award will be granted in 1979. Applications to IMPHOS; 8 rue de Penthièvre, 75008 Paris, France.

The Foulkes Foundation is a registered charity which aims to further medical research. The fellowship scheme provides financial support for recently qualified science graduates with research experience who want to study medicine and for medical graduates who want to take a science degree. In both cases the graduates must intend to do medical research after qualification. For further information contact: The Secretary, Foulkes Foundation Fellowship Scheme, The Ciba Foundation, 41 Portland Place, London W1, UK, enclosing a s.a.e. The closing date for applications is 31 March 1979. The 1978 Foulkes Foundation Fellows are **G. Belcher, C. J. Derrett, Catherine T. Elder, T. S. J. Elliott, P. R. Hearn, M. J. C. Lemon, Isabella McMillen** and **D. C. Talbot**.

Meetings

18–20 December, **Palaentological Association Annual Meeting**, Keele (Dr P. D. Lane, Dept of Geology, University of Keele, Staffs, UK).

4–5 January, **Laser–Plasma Interactions**, Bangor (T. P. Hughes, Dept of Physics, University of Essex, Colchester, Essex, UK).

23–25 January, **Inter-Agency Group on Biometeorology**, Geneva (WMO, Case Postale No. 5, CH-1211, Geneva 20, Switzerland).

29 January–2 February, **RA IV Working Group on Hydrology**, Mexico City (WMO, Case Postale, No. 5, CH-1211, Geneva, Switzerland).

29 January–24 February, **Approaches to the Molecular Genetics of Oncogenic Viruses by DNA Cloning and DNA Injection into Mice Blastocysts**, Rome (Prof Enrico Calef, Centro Acidi Nucleici del CNR, Via G Romagnosi 18/A, 00196 Rome, Italy).

12 February, **Second-order Logic and the Foundations of Mathematics**, London (The British Society for the Philosophy of Science, Mr A. Young, School of Social Sciences, University of Sussex, Falmer, Brighton, UK).

15–16 February, **Immunodeficient Animals in Cancer Research**, London (The Information Officer, MRC laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, UK).

12–23 February, **World Climate Conference**, Geneva (WMO, Case Postale No. 5, CH-1211 Geneva 20, Switzerland).

12 March, **AGM The British Society for the Philosophy of Science**, London (Mr A. Young, School of Social Sciences, University of Sussex, Falmer, Brighton, Sussex, UK).

20 March, **Mathematical Modelling of Large Scale Accidents and the Environment**, Cambridge (The Secretary, The Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex, UK).

21 March, **Models of Estuaries: Flow and Pollution**, Edinburgh (The Secretary, The Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex, UK).

3–5 April, **The Chemical Society and the RIC, Annual Chemical Congress**, Bristol (Dr John Gibson, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

9–11 April, **11th National Atomic and Molecular Physics Conference**, Liverpool (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

27–31 May, **International Prostaglandin Congress**, Washington, D.C. (Prof J. Martyn Bailey, PO Box 40591, Georgetown University Medical Center, Washington, D.C. 20016).

29 May–1 June, **Radioimmunoassay of Drugs and Hormones**, Gardone Riviera (Fondazione Giovanni Lorenzini, Via Monte Napoleone, 23 20121 Milan, Italy).

8–10 June, **Multidisciplinary Aspects of Brain Tumour Therapy**, Pavia (Fondazione Giovanni Lorenzini, Via Monte Napoleone, 23, 20121 Milan, Italy).

11–15 June, **14th International Microwave Power Symposium,** Monaco (Comite Francais d'Electrothermie, 79 rue de Miromesnil, 75008 Paris, France).

11–15 June, **3rd International Symposium on Purine Metabolism in Man,** Madrid (Unidad Metabolica, Fundacion Jimenez Diaz, Universidad Autonoma, Avida, Reyes Catolicos, 2, Madrid-3, Spain).

26–28 June, **Power from Sea Waves,** Edinburgh (The Secretary, The Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex, UK).

18–20 July, **Internal Friction and Ultrasonic Attenuation in Solids,** Manchester (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

15–19 July, **International Conference on Clinical Aspects of Cyclic Nucleotides,** Vail, Colorado (Howard Sands, National Jewish Hospital and Research Center, 3800 East Colfax Ave, Denver, Colorado 80206).

16–20 July, **Molecular Biology of Small DNA Tumour Viruses** (This replaces the Cold Spring Harbor DNA Tumour Virus Meeting) Cambridge (ICRF DNA Tumour Virus Meeting Secretary, ICRF, Lincoln's Inn Fields, London WC2, UK).

23–26 July, **Synthesis in Organic Chemistry, Cambridge** (Dr Malcolm Robinson, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

20–23 August, **1st European Symposium on Organic Chemistry,** Cologne (Dr W. Fritsche, c/o Gesellschaft Deutscher Chemiker, PO Box 90 04 40, D-6000 Frankfurt/Main 90, FRG).

3–7 September, **Practical Applications and Design of Fibre Composites,** Cambridge (Dr Peter Beaumont, Dept of Engineering, University of Cambridge, Trumpington St, Cambridge, UK).

22–25 October, **Conference on Reclamation of Contaminated land,** Eastbourne (Miss J. Bovier, Conference Secretary, Society of Chemical Industry, 14 Belgrave Square, London SW1, UK).

10–16 February 1980, **6th International Congress of Endocrinology,** Box 611E, GPO, Melbourne 3001, Australia.

7–17 July 1980, **26th International Geological Congress,** Paris (Secretariat Général du 26ème Congrès géologique international, Maison de la Géologie, 77–79, rue Claude Bernard, 75005 Paris, France).

22–27 July 1980, **International Cyclic Nucleotide Conference,** Brussels (Dr J. E. Dumont, IRIBHN, School of Medicine, 2 rue Evers, B-1000 Brussels, Belgium).

3–9 August 1980, **16th International Congress of Entomology,** Kyoto (16th International Congress of Entomology, c/o Kyoto International Conference Hall, Takara-ike, Sakyo-ku, Kyoto 606, Japan).

17–22 August 1980, **6th International Histochemistry and Cytochemistry Congress,** Brighton (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

22–26 September 1980, **International Union for Vacuum Science, Technique and Applications,** Cannes (Societe Francaise du Vide, 19 rue du Renard, 75004 Paris, France).

22–26 September 1980, **3rd International Congress on the History of Oceanography,** Woods Hole (Daniel Merriman, 298 Sperry Road, Bethany, Connecticut 06525).

21–28 August 1981, **13th International Botanical Congress,** Sydney (Dr W. J. Cram, University of Sydney, New South Wales 2006, Australia).

Reports & publications

UK & Ireland—October

Pharmaceutical Prices: A Continental View. By Dr. Klaus von Grebmer. Pp. 24. (Reprinted in translation from an article in *Die Pharmazeutische Industrie.*) (London: Office of Health Economics, 162 Regent Street, W1, 1978.) £1. [2010

Natural Environment Research Council. Annual Report of the Institute of Terrestrial Ecology for 1977. Pp.viii+93. (Cambridge: Institute of Terrestrial Ecology, 1978.) £4 net [2010

National Radiological Protection Board. NRPB-R72: A Limited Survey and Evaluation of Ultraviolet Radiation Hazards in University Laboratories By A. F. McKinlay, F. Harlen and L. M. Clark Pp 16. (Harwell, Didcot, Oxon: National Radiological Protection Board, 1978.) Obtainable from HMSO, London. £1. [2310

Information Privacy Integrity, Availability, Security, Vol 1, No. 1, September 1978. Edited by D. Sizer Pp. 1-48 Published every other month. Annual subscription: £35, $91. (Haywards Heath, Sussex. IPC Business Press (Sales and Distribution), Ltd, Oakfield House, Perrymount Road, 1978.) [2310

Tropical Products Institute. The Small-Scale Manufacture of Soap. an Economic Study. By Penelope A. Marx. (G118) Pp v+46. (London: Tropical Products Institute, 56/62 Grays Inn Road, WC1, 1978.) £1. [2310

Institute of Geological Sciences Annual Report for 1977 Pp x+226. (London Institute of Geological Sciences, 1978.) £4.50. [2410

Agricultural Development and the Rural Poor Declaration of Policy and Guidelines for Action Edited by Guy Hunter. Pp.xii+113 (London Overseas Development Institute, 10-11 Percy Street, W1, 1978.) £1.50 [2510

Thames Water—Annual Report and Accounts for the year ended 31st March, 1978. Pp. 76 (London. Thames Water Authority. New River Head, Rosebery Avenue, EC1, 1978.) [2510

Council for National Academic Awards. Directory of Postgraduate and Post-Experience Courses, 1978-79. Pp. 88. Directory of First Degree Courses, 1978-79. Pp. 184 (London Council for National Academic Awards, 344-354 Gray's Inn Road, WC1, 1978.) [2510

The Polytechnic of North London. Prospectus 1979-80. Pp 114. (London. The Polytechnic of North London, Holloway, N7, 1978.) [2510

Identification of Larval Ticks Found on Small Mammals in Britain. By K. R. Snow. Pp. 14. (Bury St. Edmunds, Suffolk. Publications Officers, Mammal Society, Larkmead, Barton Mills, 1978.) 25p+10p. p+p [2710

Natural Environment Research Council. Chemistry in the Institute of Terrestrial Ecology By S. E. Allen. Pp. 31 (Cambridge: Institute of Terrestrial Ecology, 68 Hills Road, 1978.) 75p net. [3010

National Coal Board Mining Research and Development Establishment Projects 1977/78. Pp. 49. Annual Report, 1977/78. Pp. 28. (Burton-on-Trent, Staffs.: Mining Research and Development Establishment, Ashley Road, Stanhope Bretby, 1978.) [3110

Other countries—October

Application of the International Classification of Diseases to Dentistry and Stomatology, ICD-DA Second edition. Pp. 144 (Geneva: WHO, London: HMSO, 1978) Sw.fr.20, $11. [2010

Smithsonian Contributions to Zoology, No 278 A Catalogue of the Type-Specimens of Recent Cephalopoda in the National Museum of Natural History. By Clyde E Roper and Michael J. Sweeney. Pp.iii+19 (Washington, DC: Smithsonian Institution Press, 1978. For sale by US Government Printing Office) [2310

The European Community Today and Tomorrow. Pp. 64 (Luxembourg. Office for Official Publications of the European Communities, Boite Postale 1003; 1978.) Bfr 32; 60p. [2310

United States Department of the Interior: Geological Survey. Professional Paper 935-C Crystallization and Differentiation of the Alae Magma, Alae Lava Lake, Hawaii. By Thomas L. Wright and Dallas L Peck Pp iv+20. Professional Paper 1053 Potential Effects of Deep-Well Waste Disposal in Western New York. By Roger M Waller, John T. Turk and Robert J. Dingman. Pp.v+39. Professional Paper 1055. Reconnaissance Geology and Geochronology of the Precambrian of the Granite Mountains, Wyoming By Zell E. Peterman and R. A. Hildreth. Pp.iii+22 (Washington, DC US Government Printing Office, 1978.) [2310

United States Department of the Interior: Geological Survey Bulletin 1444. Geology and Thermal History of Mammoth Hot Springs, Yellowstone National Park, Wyoming By Keith E Bargar. Pp.vii+55. (Washington, DC.: US Government Printing Office, 1978.) [2410

Smithsonian Contributions to Zoology, No. 277 *Paulidopus* The Scissor-Foot Shrimps (Crustacea: Decapoda Caridea). By Fenner A. Chace, Jr., and Lipke B. Holthuis. Pp.iii+22. (Washington, DC: Smithsonian Institution Press, 1978. For sale by US Government Printing Office) [2410

Oregon Regional Primate Research Center. Progress Report for 1977. Pp 40. (Beaverton, Oregon: Oregon Regional Primate Research Center, 505 N W. 185th Avenue, 1978) [2410

Mutants on Physiological Research of Crop Plants Report of Symposium held on July 22-23, 1976. (Gamma Field Symposia, No. 15) Pp.iv+89. (Ohmiya-machi, Ibaraki-ken, Japan Institute of Radiation Breeding, NIAS MAF, 1978) [2510

United States Department of the Interior: Geological Survey Water-Supply Paper 2048. Water Quality in the Ozark National Scenic Waterways, Missouri. By James H Barks. Pp.vii+57 Professional Paper 1022-C. Postglacial Volcanic Deposits at Mount Baker, Washington, and Potential Hazards from Future Eruptions. By Jack H. Hyde and Dwight R. Crandell Pp.v+17+1 plate. Professional Paper 1051. Field Determination of Vertical Permeability to Air in the Unsaturated Zone. By Edwin P. Weeks Pp.iv+41. Professional Paper 1068: Effects of Permafrost on Stream Channel Behaviour in Arctic Alaska By Kevin M. Scott. Pp.iii+19. (Washington, DC.: US Government Printing Office, 1978.) [2510

Deutsches Hydrographisches Institut, Hamburg. Jahresbericht 1976/77. Pp. 137.) Hamburg: Deutsches Hydrographisches Institut, 1978.) [2510

World Health Organization Technical Report Series, No 623: Induced Abortion: Report of a WHO Scientific Group. Pp. 65. Sw.fr.7. Public Health Papers, No. 69: Poverty, Development and Health Policy. By Brian Abel-Smith and Alcira Leiserson. Pp. 109. Sw.fr 10; $5. Geneva. WHO, London. HMSO, 1978) [3010

CERN—European Organization for Nuclear Research. CERN 78-07: The Nodal System for the SPS. By M C Crowley-Milling and G. C. Shering. Pp.vii+98. (Geneva. CERN, 1978.) [3010

The Worldwide Loss of Cropland. By Lester R. Brown. Pp. 48. (Worldwatch Paper No. 24.) (Washington, DC.: Worldwatch Institute, 1776 Massachusetts Avenue, N.W, 1978) $2. [3110

Smithsonian Contributions to Zoology, No. 251. A Revision of the North American Moths of the Superfamily Eriocranioidea with the Proposal of a New Family, Acanthopteroctetidae (Lepidoptera). By Donald R Davis Pp iv+131. (Washington, DC.: Smithsonian Institution Press, 1978. For sale by US Government Printing Office) [3110

Recent scientific and technical books

Applied biology

ANDERSEN, K. Lange, MASIRONI, R., RUTENFRANZ, and SELIGER, C. In collaboration with DEGRE, S., TRYGG, K., and ORGIM, M. Habitual Physical Activity and Health. (WHO Regional Publications. European Series No. 6.) Pp.188. ISBN-92-9020-106.1. (Copenhagen. WHO, Regional Office for Europe, London. HMSO, 1978.) Sw.fr.25, $12.50.

BARLATI, Sergio, and GIULI-MORGHEN, Carlo (edited by). Avian RNA Tumor Viruses. (Proceedings of the ICREW-EMBO Workshop, Pavia, 9th-12th September 1977.) Pp.xv+355. (Padua: Piccin Medical Books, 1978.) $30.

BRANDLY, C. A., and CORNELIUS, Charles E. (edited by). Advances in Veterinary Science and Comparative Medicine, Vol. 22. Pp.xii+325. ISBN-0-12-039222-4. (New York and London. Academic Press; a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) $35, £22.75.

BROOKS, Geo. F., GOTSCHLICH, Emil C., HOLMES, King K., SAWYER, William D., and YOUNG, Frank E. (edited by). Immunobiology of *Neisseria gonorrhoeae*. (Proceedings of a Conference held in San Francisco, California, 18-20 January 1978). Pp.xxii+399. ISBN-0-914826-18-2. (Washington, DC.: American Society for Microbiology, 1978.) $15.

CALMAN, Kenneth C., and PAUL, John. An Introduction to Cancer Medicine. Pp.200. ISBN-0-333-21277-0. (London and Basingstoke: The Macmillan Press, Ltd., 1978.) Hard cover £8; Paperback £3.95.

COCHRAN, Alistair J. Man, Cancer and Immunity. Pp.xi+206. ISBN-0-12-177550-X. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £7.80; $16.15.

CORNER, M. A., BAKER, R. E., van de POLL, N. E., Swaab, D. F., and UYLINGS, H. B. M. (edited by). Maturation of the Nervous System. (Progress in Brain Research, Vol. 48.) Pp xii+425. ISBN-0-444-80036-0. (Amsterdam, New York and Oxford: Elsevier Scientific Publishing Company, 1978.) Dfl. 160; $71.25.

COTTRAL, George E. (edited by). Manual of Standardized Methods for Veterinary Microbiology. Pp.731. ISBN-0-8014-1119-X. (Ithaca and London: Comstock Publishing Associates, a Division of Cornell University Press, 1978.) $35.

COX, B., MORRIS, L. D., and WESTON, A. H. (edited by). Pharmacology of the Hypothalamus. (Proceedings of a British Pharmacological Society International Symposium on the Hypothalamus, held on Thursday, September 8th, 1977, at the University of Manchester, UK.) Pp.277. ISBN-0-333-22606-2. (London and Basingstoke. The Macmillan Press, Ltd., 1978.) £12.95

DAUGAARD, J. Symptoms and Signs in Occupational Disease: a Practical Guide. Pp.95. ISBN-0-8151-2293-4. (Copenhagen: Munksgaard, 1978. Distributed in North, South and Central America by Year Book Medical Publishers, Inc.) np.

DENIKER, P., RADOUCO-THOMAS, C., and VILLENEVE, A. (chief editors). BARONET-LACROIX, D., and GARCIN, F. (associate editors). Neuro-Psychopharmacology (Proceedings of the Tenth Congress of the Collegium Internationale Neuro-Psychopharmacologicum, Québec, July 4-9, 1976). Vol. 1: Pp.xxvii+1-932. Vol. 2: Pp.xix+933-1737. ISBN-0-08-021506-8. (Oxford and New York: Pergamon Press, 1978.) £85.

DIAMOND, Marian Cleeves, and KORENBROT, Carol Cleaves (edited by) Hormonal Contraceptives, Estrogens, and Human Welfare. Pp xiii+146. ISBN-0-12-214750-2. (New York and London. Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) $12.50, £8.10

DIXON, Frank J., and KUNKEL, Henry G. (edited by). Advances in Immunology, Vol. 26. Pp.xi+347. ISBN-0-12-022426-7. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) $27.50, £17.85.

DOLLERY, Colin. The End of an Age of Optimism. Medical Science in Retrospect and Prospect. (The Rock Carling Fellowship, 1978.) Pp.viii+95. ISBN-0-900574-29-1 (London: Nuffield Provincial Hospitals Trust, 1978.) £3.95 net.

ELLIS, G. P., and WEST, G. B. (edited by). Progress in Medicinal Chemistry, Vol. 15. Pp.x+433. ISBN-0-7204-0655-2. (Amsterdam, New York and Oxford: North-Holland Publishing Company, 1978.) Dfl. 155; $69.

FOGH, Jorgen, and GIOVANELLA, Beppino (edited by) The Nude Mouse in Experimental and Clinical Research Pp xvi+502 ISBN-0-12-261860-2. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) $31; £20.15.

GARATTINI, Silvio, GOLDIN, A., HAWKING, F., and KOPIN, I. J. (edited by) SCHNITZER, R. J. (consulting editor). Advances in Pharmacology and Chemotherapy, Vol. 15. Pp x+325. ISBN-0-12-032915-8. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) $31.50; £20.45.

GARDNER, D. L. (edited by). Diseases of Connective Tissue. (Symposium organized by The Royal College of Pathologists, delivered in London in February 1978.) Pp 241. (London: *Journal of Clinical Pathology*, BMA House, Tavistock Square, WC1. Published for The Royal College of Pathologists.) Inland £6, Abroad US$15.

GARROW, J. S. Energy Balance and Obesity in Man. Second edition completely revised. Pp.xii+243. ISBN-0-444-80046-8. (Amsterdam, New York and Oxford: Elsevier/North-Holland Biomedical Press, 1978.) Dfl. 123; $53.50.

GAY, Steffen, and MILLER, Edward J. Collagen in the Physiology and Pathology of Connective Tissue. Pp.109. ISBN-3-437-10544-2. (Stuttgart and New York: Gustav Fischer Verlag, 1978.) $21.10

GIFFORD, Jr., James F. (edited by). Undergraduate Medical Education and the Elective System: Experience with the Duke Curriculum, 1966-75. Pp.xiv+243 ISBN-0-8223-0394-9. (Durham, NC.: Duke University Press, 1978.) np.

GUILLEMINAULT, Christian, and DEMENT, William C. (edited by). Sleep Apnea Syndromes. (Kroc Foundation Series, Vol. 11.) Pp.xv+372. ISBN-0-8451-0301-6. (New York: Alan R. Liss, Inc., 1978. $34. Available in Europe, the UK and the Middle East exclusively from European Book Service, Hogeweyselaan 119, Weesp, The Netherlands. Dfl. 102.

HOFFMANN-OSTENHOF, O., BREITENBACH, M., KOLLER, F., KRAFT, D., and SCHEINER, O. Affinity Chromatography. Biospecific Sorption—The First Extensive Compendium on Affinity Chromatography as Applied to Biochemistry and Immunochemistry. (Proceedings of an International Symposium held at Vienna, Austria, 20-24 September 1977.) Pp.xvi+374. ISBN-0-08-022632-9. (Oxford and New York: Pergamon Press, 1978.) £20.

HOLLING, C. S. (edited by). Adaptive Environmental Assessment and Management. (International Series on Applied Systems Analysis, Vol. 3.) Pp xviii+377. ISBN-0-471-99632-7. (Chichester and New York: Wiley-Interscience, John Wiley and Sons, 1978.) £7.75.

HORSFALL, James G., and COWLING, Ellis B. (edited by). Plant Disease. an Advanced Treatise. Vol. 2 How Disease Develops in Populations Pp xx+436. ISBN-0-12-356401-8 (v.2). (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) $37, £24.05.

INTERNATIONAL DIRECTORY OF SPECIALIZED CANCER RESEARCH AND TREATMENT ESTABLISHMENTS. Second edition. (UICC Technical Report Series, Vol. 33.) Pp.xviii+724. ISBN-92-9018-033-1. (Zurich: International Union Against Cancer, 1978.) np.

INTERNATIONAL VIROLOGY IV. (Abstracts of the Fourth International Congress for Virology, held at The Hague, The Netherlands, August 30—September 6, 1978.) Pp.664. ISBN-90-220-0677-8. (Wageningen, The Netherlands: Centre for Agricultural Publishing and Documentation, 1978.) np.

LAVENDER, J. Peter (edited by). Clinical and Experimental Applications of Krypton 81m. (*British Journal of Radiology*, Special Report No. 15.) Pp.ix+193. ISBN-0-905749-01-4. (London: British Institute of Radiology, 1978.) £12.

LAVER, W. G., BACHMAYER, H., and WEIL, R. (edited by). The Influenza Virus Hemagglutinin Symposium, Baden near Vienna, March 21-23, 1977. (Topics in Infectious Diseases, Vol. 3.) Pp.xii+259. ISBN-3-211-81459-0. (Wien and New York: Springer-Verlag, 1978.) DM 54; $27.

LEONARD, B. J. (edited by). Toxicological Aspects of Food Safety. (Proceedings of the European Society of Toxicology, Meeting held in Copenhagen, June 19-22, 1977.) (Archives of Toxicology, Supplement 1.) Pp xi+392 ISBN-3-540-08646-3. (Berlin and New York: Springer-Verlag, 1978.) DM 78, $39

LITTLEFIELD, John W., DE GROUCHY, Jean, and EBLING, F. J. G. (edited by). Birth Defects. (Proceedings of the Fifth International Conference, Montreal, Canada, 21-27 August, 1977. Sponsored by the National Foundation-March of Dimes, and organized by International Birth Defects Congress, Ltd.). Pp xxii+451. ISBN-0-444-90024-1. (Amsterdam and Oxford: Excerpta Medica, 1978.) Dfl. 190; $82.75.

MANNINEN, Vesa, and HALONEN, Pentti I. (edited by). Sudden Coronary Death (4th Paavo Nurmi Symposium, Helsinki, September 15-17, 1977.) (Advances in Cardiology, Vol. 25.) Pp.viii+232. ISBN-3-8055-2881-7. (Basel, London and New York: S. Karger, 1978.) SFr. 118; DM 141, $70.75.

MASSRY, Shaul G., RITZ, Eberhard, and RAPADO, Aurelio (edited by). Homeostasis of Phosphate and Other Minerals. (Advances in Experimental Medicine and Biology, Vol. 103.) Pp.xv+552. ISBN-0-306-40008-1. (New York and London: Plenum Press, 1978.) $59.40.

MELCHERS, F., POTTER, N., and WARNER, N. (edited by) Lymphocyte Hybridomas (Second Workshop on "Functional Properties of Tumors of T and B Lymphocytes". Sponsored by the National Cancer Institute (NIH), April 3-5, 1978, Bethesda, Maryland, U.S.A.) (Current Topics in Microbiology and Immunology, Vol. 81). Pp.xxiv+246. ISBN-3-540-08810-5 (Berlin and New York: Springer-Verlag, 1978.) DM 48, $24.

MITCHELL, Ralph (edited by) Water Pollution Microbiology, Vol. 2. Pp x+442. ISBN-0-4710-1902-X. (New York and Chichester. Wiley-Interscience, John Wiley and Sons, 1978). £17.60.

MORTON, Newton E., and CHUNG, Chin Sik (edited by). Genetic Epidemiology Pp.x+550. ISBN-0-12-508050-6 (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978) $22, £14.30.

NEWBERNE, Paul M., and BUTLER, W. H. (edited by) Rat Hepatic Neoplasia Pp xii+288 ISBN-0-262-14029-2 (Cambridge, Mass. and London: MIT 1978.)

NIEBURGS, Herbert E. (edited by) Prevention and Detection of Cancer. Part 1: Prevention. Vol 2: Etiology—Prevention Methods. Pp xix+1199-2404. ISBN-0-8247-6682-2. (New York and Basel: Marcel Dekker, Inc., 1978.) Sw. francs 190.

NRIAGU, J. O. (edited by). The Biogeochemistry of Lead in the Environment. Part B: Biological Effects (Topics in Environmental Health, Vol. 1B.) Pp.x+397. ISBN-0-444-80050-6. (Amsterdam, New York and Oxford: Elsevier/North-Holland Biomedical Press, 1978.) Dfl. 155; $67.50.

O'KEEFE, John, and NADEL, Lynn. The Hippocampus as a Cognitive Map. Pp xiv+570. ISBN-0-19-857206-9. (Oxford. Clarendon Press; Oxford and London: Oxford University Press, 1978.) £25 net.

PAOLETTI, Rodolfo, and KRITCHEVSKY, David (edited by) Advances in Lipid Research, Vol. 16. Pp.xi+410. ISBN-0-12-024916-2. (New York and London. Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) $34; £22.10.

PATTYN, S. R. (edited by) Ebola Virus Haemorrhagic Fever (Proceedings of an International Colloquium on Ebola Virus Infection and Other Haemorrhagic Fevers, held in Antwerp, Belgium, 6-8 December, 1977.) Pp.xii+436. ISBN-0-444-80060-3. (Amsterdam and New York. Elsevier/North-Holland Biomedical Press, 1978.) Dfl. 128, $57.

PETERSON, Donald R., and THOMAS, David B. Fundamentals of Epidemiology: An Instruction Manual. Pp.xvi+97. ISBN-0-669-01901-1. (Lexington, Mass. and Toronto. Lexington Books, D. C. Heath and Company, Farnborough Hants.: Lexington Books, Teakfield, Ltd., 1978.) £7.95.

PIERCE, G. Barry, SHIKES, Robert, and FINK Louis M. Cancer: a Problem of Developmental Biology. Pp.xiii+242. ISBN-0-13-113373-X. (Englewood Cliffs, NJ. and Hemel Hempstead. Prentice-Hall, 1978.) £11.65.

POLONOVSKI, J. (edited by). Cholesterol Metabolism and Lipolytic Enzymes. Pp.211. ISBN-0-89352-010-1. (New York and Paris: Masson Publishing U.S.A., Inc.; Tunbridge Wells: Abacus Press, Ltd., 1977.) £21.

REID, Eric (edited by). Blood Drugs and other Analytical Challenges. (Methodological Surveys in Biochemistry, Vol. 7.) Pp.xi+355. (Chichester: Ellis Horwood, Ltd., 1978. Distributed by John Wiley and Sons, Chichester and New York.) £19.50.

RITCHIE, Robert F. (edited by). Automated Immunoanalysis, Part 2. (Clinical and Biochemical Analysis: a Series of Monographs and Textbooks, Vol. 7.) Pp.xiii+335-620. ISBN-0-8247-6679-2. (New York and Basel: Marcel Dekker, Inc., 1978.) $29.75.

RITZ, E., MASSRY, Shaul, HEIDLAND, A., and SCHAEFER, K. (edited by). Pathophysiological Problems in Clinical Nephrology (Contributions to Nephrology, Vol. 14.) Pp.vi+210. ISBN-3-8055-2910-4. (Basel, London and New York: S. Karger, 1978.) SFr/DM 88; $44.

ROBERTS, Ronald J. (edited by). Fish Pathology. Pp.x+318. ISBN-0-7020-0674-2. (London: Baillière Tindall, 1978.) £21.

RUSHMER, Robert F. Humanizing Health Care: Alternative Futures for Medicine. Pp.xii+210. ISBN-0-262-68032-7. (Cambridge, Mass. and London: The MIT Press, 1978.) np.

RUSSELL, Diane Haddock, and DURIE, Brian G. M. Polyamines as Biochemical Markers of Normal and Malignant Growth. (Progress in Cancer Research and Therapy, Vol. 8.) Pp.xiii+178. ISBN-0-89004-116-4. (New York: Raven Press, 1978.) $29.25

SERROU, B., and ROSENFELD, C. (edited by). Human Lymphocyte Differentiation: Its Application to Cancer. (Proceedings of the International Symposium on Human Lymphocyte Differentiation. Its Application to Cancer, held in Montpellier, France, 2-4 March, 1978.) (INSERM Symposium, No. 8.) Pp.xvii+423. ISBN-0-7204-0664-1. (Amsterdam, New York and Oxford: North-Holland Publishing Company, 1978). Dfl. 130, $56.75.

STAVE, Uwe, and WEECH, A. Ashley (edited by) Perinatal Physiology. Pp.xxii+851 ISBN-0-306-30999-8. (New York and London. Plenum Medical Book Company, 1978.) $71.40.

STOCKING, Barbara, and MORRISON, Stuart L. The Image and the Reality. a Case-Study of the Impacts of Medical Technology. Pp x+80. ISBN-0-19-721220-4. (Oxford: Oxford University Press, 1978. Published for the Nuffield Provincial Hospitals Trust.) £3 net.

UNIVERSITY OF EDINBURGH

TECHNICIAN

Required for the DEPARTMENT OF CHEMISTRY in the S R.C supported Edinburgh University Fourier Transform NMR Service. The successful applicant will be required to assist in the operation of the Varian XL—100 and Bruker WH 360 multinuclear magnetic resonance spectrometers and in the general running of the service under the direction of Dr I H. Sadler. Experience in the field of high resolution NMR and with Fourier Transform NMR spectrometers would be an advantage Qualifications H N C or equivalent. The appointment will be for four years with the possibility of renewal Salary on scale £3,654 to £4,365 per annum (under review). Applications together with the names of two technical referees should be submitted as soon as possible Ref NT060

Application forms for the above post can be obtained from the Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS Telephone 031-556 2930 8638(A)

UNIVERSITY OF CAMBRIDGE

INSTITUTE OF ASTRONOMY

RESEARCH APPOINTMENTS IN THEORETICAL ASTRONOMY

Applications are invited for S R C.-supported postdoctoral positions for research in theoretical astronomy Appointments will be for two years in the first instance, with possible extension for a third year The salary scale (under review) is £4,113 (age 25) to £6,555 (age 35), plus U S S benefits The preferred starting date is on or before October 1979 Applications should be sent to Professor M J Rees, Institute of Astronomy, Madingley Road, Cambridge CB3 0HA by January 30, 1979 Applicants should themselves please ask three referees to write to Professor Rees by the same date

DATA ANALYSIS FOR X-RAY ASTRONOMY

An S R C -supported post is available from October 1979 for a postdoctoral worker to assist in the analysis of X-ray astronomical data The work arises out of collaboration with groups elsewhere Travel to the groups involved—and, in particular, several visits to the U S of about one month duration—will be necessary The post is tenable for up to three years, at a starting salary (under review) of up to £4,631 (age-point 27) plus U S S benefits Further information can be obtained from Dr A C Fabian, Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, and applications must be received by January 30, 1979 Applicants should themselves ask three referees to write to Dr Fabian by the same date.

UNIVERSITY OF EDINBURGH

DEPARTMENT OF MOLECULAR BIOLOGY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the post of Postdoctoral Research Fellow to work on a project funded by the S R C. The project is concerned with the separate isolation of copy DNA sequences from *Xenopus* oocyte messenger RNA by molecular cloning and applicants should have experience of nucleic acid research and/or molecular cloning techniques

The salary is on Range IA (£3,883 to £6,555 per annum) and the post is for three years

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent to Dr P J Ford, Department of Molecular Biology, King's Buildings, Mayfield Road, Edinburgh EH9 3JR Please quote Reference 5035 8610(A)

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following

FACULTY OF SCIENCE

A.R.G.C. RESEARCH FELLOW— BIOLOGICAL CHEMISTRY

A Research Fellow is required to work in the area of endogenous growth control substances in Eucalyptus species under the direction of Associate Professor W D Crow (Department of Chemistry) and Dr D M Paton (Department of Botany) Candidates should hold a Ph D. degree or equivalent and have some experience in working with plant material in a chemically-oriented manner Knowledge of, or experience in plant physiology/biochemistry would be of considerable value The Fellow will work in collaboration with senior members of the Departments of Botany, Chemistry and Forestry, full research facilities are available, including access to high-field n m r

The position will be funded by the Australian Research Grants Committee for three years from February 1, 1979

CLOSING DATE **DECEMBER 9, 1978.**

Salary on appointment will be in accordance with qualifications and experience within the range $A15,179 to $A17,220 per annum. Current exchange rates $A1 $US1 14 £0.58

Reasonable appointment expenses are paid Superannuation benefits are available for applicants who are eligible to contribute Assistance with housing is provided for an appointee from outside Canberra

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 8646(A)

BIOCHEMISTRY

UNIVERSITY OF CALIFORNIA, SANTA CRUZ

Applications are invited for new faculty position jointly with Merrill College in Chemistry at University of California, Santa Cruz Preference will be given to candidates with research interests in area of biochemical approaches to cellular regulation. Teaching duties include both undergraduate and graduate courses in metabolism and regulation. Likely level of this appointment is Assistant Professor

Send resume, brief outline of future research/teaching plans, and three letters of reference to

Thomas Schleich, Chairperson
Biochemistry Search Committee
Division of Natural Sciences
University of California
Santa Cruz, California 95064

Closing date for this position is January 17, 1979.

An Equal Opportunity/Affirmative Action Employer.

HOUGHTON POULTRY RESEARCH STATION
GENETICIST

A vacancy exists in the Leukosis Experimental Unit for a geneticist to study the inheritance and nature of resistance of chickens to oncogenic and other viruses, and to assist in the formulation of breeding programmes for the Institute's flocks

Applicants must have a first or upper second class honours degree, with genetics as a major subject in the first or a higher degree, and preferably a Ph D or at least 3 years' relevant postgraduate experience A minimum of 4 years' relevant postgraduate experience is required for the S S O grade

The appointment will be to the Higher Scientific Officer grade (£4,101 by 8 to £5,448) or the Senior Scientific Officer grade (£5,154 by 8 to £6,898), grade and starting salary depending upon experience Non-contributory superannuation scheme.

Further particulars and application forms from the Station Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs. PE17 2DA Closing date for applications is January 10, 1979.

8507(A)

UNIVERSITY OF GLASGOW
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Post-doctoral Research Assistant supported by the M R.C. to work with Dr H. G. Nimmo on the purification and regu-latory properties of the mitochondria glycerol phosphate acyltransferase from ammalian liver Prior experience of working with membrane-bound enzymes would be an advantage.

The appointment will initially be for one year, from January 1, 1979 renewable for two further years subject to satisfactory progress

Salary within range £3,883 to £4,88 on Range 1A of the salary scale for Research and Analogous staff according to age and experience Superannuation Scheme will apply.

Applications, with a curriculum vitae and the names of two referees should be sent to Dr H G. Nimmo Department of Biochemistry, University of Glasgow, Glasgow G1 8QQ, by December 22, 1978.

In reply please quote Ref No 4319M.

HERIOT-WATT UNIVERSITY

DEPARTMENT OF BREWING & BIOLOGICAL SCIENCES

RESEARCH ASSOCIATE—ESTUARINE ALGAE

Applications are invited for the post of N.E.R.C. Research Associate to work on the ecology of intertidal algae in a small estuary polluted by very low pH effluents with very high nutrient status and elevated levels of certain metals. The project is under the supervision of Dr M. Wilkinson. Applicants should have an honours degree in a biological subject. The successful candidate may be eligible to register for a higher degree.

Initial salary will be in the range £3,384 to £3,883 per annum and the post is for three years commencing January 1, 1979.

Informal enquiries may be made to Dr M. Wilkinson, Department of Brewing & Biological Sciences, Tel 031-225 8432, ext. 347.

Application forms are available from the Staff Officer, Chambers Street, Edinburgh EH1 1HX to whom completed forms should be returned by Friday, December 15, 1978. Ref. 14/78 8593(A)

UNIVERSITY OF VICTORIA, B.C. CANADA

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

Applications are invited for the position of

ASSISTANT PROFESSOR

beginning July 1, 1979. Candidates should have strong teaching and research interests in one or more of the following fields: immunology, protein biochemistry, molecular genetics (recombinant DNA), virology. The successful applicant will be required to teach at the undergraduate and graduate levels and carry on an active research program. A Ph.D. is required and postdoctoral experience desirable.

Applications, including a *curriculum vitae*, list of publications, a brief statement of research plans, and the names of three referees who have been requested to send letters of recommendation should be sent to Professor A. T. Matheson, Chairman, Department of Biochemistry and Microbiology, University of Victoria, P.O. Box 1700, Victoria, B.C., Canada V8W 2Y2, as soon as possible 8663(A)

UNIVERSITY OF GENEVA (SWITZERLAND)

POSTDOCTORAL RESEARCH APPOINTMENT

is immediately available at the Laboratory for Applied Chemistry for an *inorganic chemist*, *solid state chemist* or *solid state physicist* interested in joining an experimental programme (Swiss National Science Foundation) on the synthesis and the properties of ferroelectric and magnetically ordered ferroelectric, magnétoelectric materials. Renewal of the appointment is possible from year to year.

Applicants should submit résumé, publication list and names of two referees to:

Professor H. Schmid,
Applied Chemistry Laboratory,
University of Geneva,
30, quai Ernest-Ansermet,
CH-1211 Geneva 4. 8645(A)

THE QUEEN'S UNIVERSITY OF BELFAST

RESEARCH OFFICER

DEPARTMENT OF MEDICAL GENETICS

Applicants must hold a University degree, or equivalent qualification, and have experience in Biochemistry, or Chemistry. The Department is involved in culture of various tissue including blood, skin, and aminotic fluid cells. The Research Officer will be responsible for initiating biochemical techniques applicable to tissue culture. Knowledge and experience in enzyme electrophoresis, column chromatography, would be an advantage. Duties will include participation in the Department's research and teaching programmes and assisting with a number of postgraduate research projects.

Salary scale (under review) £3,885 to £6,555 per annum with superannuation.

Further particulars and application forms may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: December 22, 1978. (Please quote Ref 78/N). 8624(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PATHOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

(£4,382 to £5,367)

Applications are invited for the above post from biological scientists with experience in cell membrane or protein biochemistry, and immunology. The successful applicant will join a new M.R.C. funded five-year programme to investigate the use of membrane antigens as a possible EB-virus vaccine as part of a wider study, technical help will be available. The appointment will be for one year initially, renewable annually.

Replies in writing, giving the names and addresses of two referees to Professor M. A. Epstein, Department of Pathology, The Medical School, University Walk, Bristol BS8 1TD, by December 15, 1978 8614(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

The Medical School

RESEARCH OFFICER

Applications are invited from suitably qualified graduates (preferably post doctoral) for a post as Research Officer in the Department of Psychiatry. The successful candidate will join the research unit of the Department and, although the work will be primarily concerned with pharmacological and biochemical research into brain neurotransmitter mechanisms, he/she will also have freedom to develop his/her own research interests.

Commencing salary according to age qualifications and experience on either the Range 1B salary scale £3,384 to £4,882 per annum or the Range 1A salary scale £3,883 to £6,555 per annum. The post is available for up to three years. Membership of the appropriate University superannuation scheme will be required.

Further enquiries may be made to Professor D. Eccleston (telephone 0632 25131, Ext. 3167). Applications (three copies) together with the names and addresses of three referees should be sent to the Senior Administrative Assistant, The Medical School, University of Newcastle upon Tyne NE1 7RU, from whom further particulars may also be obtained, not later than December 22, 1978. 8615(A)

THE UNIVERSITY OF JUBA—SUDAN

Applications are invited for the following posts in the COLLEGE OF NATURAL RESOURCES AND ENVIRONMENTAL STUDIES (Staff are urgently required in Juba by mid-February 1979).

1. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN ANIMAL PRODUCTION.
2. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN FISHERIES
3. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN WILDLIFE
4. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN FORESTRY.
5. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN LAND USE
6. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN ECOLOGY.
7. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN BIOCHEMISTRY.
8. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN PLANT PROTECTION.
9. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN PHYSICS.
10. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN SOIL SCIENCE.
11. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN ANIMAL PHYSIOLOGY.

Salary scales: Professor £S5,460 per annum; Associate Professor £S4,030 to £S4,550 per annum; Lecturer £S ,500 to £S3,500 per annum (these scale exclude cost of living allowance) (£S1 equals £1 27 sterling). The British Government may supplement salaries in range £3,408 to £3,966 per annum (sterling) for married appointees or £1,092 to £1,734 per annum (sterling) for single appointees (normally free of all tax and presently under review) and provide children's education allowances and holiday visit passages. Family passages various allowances, superannuation scheme; annual overseas leave. Detailed applications (two copies), including a curriculum vitae and naming three referees, should be sent by air mail, not later than December 28, 1978 to the Secretary General, University of Juba, P.O. Box 82, Juba, Sudan. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 8589(A)

SCIENCE, ENGINEERING AND TECHNOLOGY

The British Council

OVERSEAS CAREER SERVICE

The British Council, which has a responsibility for Britain's cultural and educational relations overseas, will have some vacancies in 1979. The Council is represented in over 80 countries. Overseas Career Service staff must expect to serve wherever they are posted, and to spend two thirds or more of their working lives abroad.

Staff joining the Overseas Career Service bring with them a wide variety of skills and experience and most appointments are made with a view to eventual promotion on merit to senior managerial posts. The Council has a continuing need for a proportion of new staff with qualifications and experience in science and engineering, as well as in the other specialist subjects of interest to the Council. English language teaching and librarianship for example.

We should like to hear from you if you have a background in science or engineering and some postgraduate experience in research, industry, education or administration. An essential requirement is the personal and managerial qualities which overseas representation demands.

Recently, most successful candidates for the Overseas Career Service have been between 25 and 32 years of age, but we should be glad to hear from younger or older candidates who have the necessary background. Only in exceptional cases is appointment offered to candidates over the age of 40.

The initial salary is in the region of £5,300 possibly higher for particularly well-qualified candidates, and terms and conditions of service are in line with those of comparable organisations in the public sector: free accommodation and overseas allowances, including children's education allowances, are provided while overseas.

For further details and an application form, please write or telephone quoting C1 to Staff Recruitment Department, The British Council, 65 Davies Street, London W1Y 2AA, telephone 01-499 8011 extension 3041

8585(A)

CSIRO AUSTRALIA

Postdoctoral Research fellow

Division of Fisheries and Oceanography Cronulla, NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees—2400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: **FISHERIES BIOLOGY**

Duties: Initially to develop and supervise a research programme on the highly migratory fish species that occur in the seas adjacent to Australia. Field investigations on the Division's vessels and on fishing vessels in the open sea will be involved. Temporary posting to other parts of Australia may be required.

Qualifications: A Ph.D or equivalent in one of the ecological sciences with heavy emphasis on mathematics and statistics and the use of computers Specific training and/or experience in population dynamics is desirable.

Salary: Research Scientist: $A14829 to $A18177 p.a. or Senior Research Scientist. $A18819 to $A21543 p.a. A higher salary might be offered to a more experienced applicant

Tenure: A fixed-term appointment of 3 to 5 years, with superannuation benefits.

Applications **in duplicate**, stating **full** personal and professional details, the names and addresses of at least two professional referees, and **quoting reference number 320/809** should reach:

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, London WC2R 3EH by **29th December 1978.**

Applications in U.S.A. and Canada should be sent to:

The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

8618(A)

Camden & Islington Area Health Authority (T)

Whittington Hospital

Probationary Grade/ Basic Grade Biochemist

required for the Endocrine Laboratory in the newly built and well-equipped Pathology Department of the above University Hospital Applicants should have an appropriate Science degree. Experience, though desirable, is not essential as training will be given.

Salary on the scale £3,486 to £3,916 or £4,038 to £4,899, plus £364 London Weighting Allowance

Application forms obtainable from: Hospital Personnel Dept., Whittington Hospital, Highgate Hill, London N 19
Tel. 01-272 9679.

8655(A)

UNIVERSITY OF RHODESIA

CHAIR OF MATHEMATICS

Applications are invited for the post of Professor and Head of the Department of Mathematics which will become vacant on the retirement of the Foundation Professor, Professor R A Manwell, on December 2, 1978. The Chair may be filled from any branch of Mathematics but, other things being equal, preference will be given to a candidate who has an interest in applicable Mathematics

Qualifications Ideally, applicants should hold a doctorate and have held a senior university appointment in Mathematics.

Salary Scale (Approx. Stg equiv) £10,291 by £387 to £12,226.

Conditions. Appointment will be on permanent, pensionable terms and these include family passages and allowance towards transport of effects, installation loan of up to half of one year's salary if required; unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia, sabbatical leave and biennial visits with travel allowances, superannuation and medical aid schemes

Applications (6 copies) giving full details of personal particulars, qualifications, experience, research, publications together with the names and addresses of three referees should be sent to the Assistant Registrar (Science), University of Rhodesia, P O Box MP 167, Mount Pleasant, Salisbury, Rhodesia Overseas applicants should send an additional copy of their applications to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Further particulars may be obtained from either of the above

Closing date for receipt of applications **December** 31, 1978.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 01-233 8727) or their nearest British Consular Office

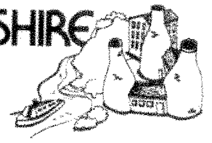
NORTH STAFFORDSHIRE HEALTH DISTRICT



TOP GRADE BIOCHEMIST

Applications are invited from science graduates for the post of Top Grade Biochemist at the North Staffordshire Hospital Centre. Wide experience is essential and the possession of higher qualifications is desirable.

The successful candidate will participate in the routine running of the department and will be expected to pursue his or her own research interests. There are close relations with the University of Keele and opportunities exist for participation in Post Graduate teaching and lecturing. The department, which is one of the largest in the country, is well equipped and extensively automated and computerised. It is situated in a modern building.

Those interested in visiting the laboratory should contact Dr. J. A. H. Brown, Consultant Pathologist, Telephone 0782-49144 Ext. 4669.

Further details regarding the appointment are available from the District Personnel Officer, The Limes, Hartshill Road, Hartshill, Stoke-on-Trent, ST4 7PS.

Closing date for completed applications: January 31, 1979.

8594(A)

Staffordshire Area Health Authority

CSIRO
AUSTRALIA
Postdoctoral Research fellow
Division of Mineralogy North Ride, NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: **ISOTOPE GEOCHEMISTRY**

General: The Division's research programme includes development of surface and subsurface geochemical techniques for mineral exploration. Isotopic methods are being tested, and significant progress has been made in applying lead isotopes to exploration for stratiform base metal sulfide deposits.

Duties: To conduct lead isotope measurements on samples from a variety of geological environments and ore types, and to evaluate the applicability of results in mineral exploration. Field work and close liaison with mining companies will be required.

Qualifications: A Ph.D degree or the equivalent with experience in mass spectrometry, preferably including lead isotopes at trace levels A knowledge of ore mineralogy is desirable.

Salary: Research Scientiest or Senior Research Scientist. $A14,829 to $A21,543 p.a.

Tenure: Three-year fixed term appointment.

Applications **in duplicate**, stating **full** personal and professional details, the names and addresses of at least two professional referees, and **quoting reference number 602/44**, should reach:

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, London WC2R 3EH by **29th December 1978.**

Applications in U.S.A. and Canada should be sent to:

APPOINTMENTS VACANT

New Fermentation Products

Sefton Park, Bucks

The Glaxo Group of Companies has an impressive history of exploiting fermentation products. Our Fermentation Research Division, situated in pleasant surroundings at Stoke Poges in South Buckinghamshire, has an extensive programme to investigate the biosynthetic potential of a variety of micro-organisms.

We are seeking to fill the following appointments:

Laboratory Head—Microbiologist

This would be suitable for a senior research microbiologist capable of supervising a graduate and technical staff and able to liaise with biochemists, chemists and fermentation technologists within a progressive multi-disciplinary group.

He or she will be responsible for organising and reporting the work of a laboratory and should combine an understanding of secondary metabolite biosynthesis with the ability to apply this knowledge to evaluate the potential of selected organisms for new product formation.

Starting salary in the range of £5,320 p.a. to £7,073 p.a. subject to qualifications and experience. Reference number: 252.

Microbial Geneticist

A newly qualified Ph.D. Microbial Geneticist with a biochemical background is required for work on the genetics of secondary metabolite production in micro-organisms.

Starting salary £4,200 p.a. Reference number: 253.

In addition to the above salary there is a London Allowance of £258.50 per annum, and quarterly and annual bonuses which at present total 10.27% per annum.

Flexible hours of work are in operation and assistance with relocation expenses is available in appropriate cases. When applying for an application form please quote reference numbers as above.

Please apply to:
R. E. Nolan, Personnel Officer
Glaxo-Allenburys Research (Greenford) Ltd.,
Greenford Road, Greenford, Middlesex

8660(A)

Glaxo-Allenburys Research (Greenford) Limited

ANIMAL VIRUS RESEARCH INSTITUTE

APPOINTMENT OF DIRECTOR

Applications are invited for the post of Director of The Animal Virus Research Institute, Pirbright, Surrey, which will become vacant on the retirement of the present Director, Dr J. B. Brooksby, C.B.E., in December 1979. The Institute, which is grant-aided by the Agricultural Research Council, has its own Governing Body and is engaged in research on the virus diseases of animals.

Applicants should have high scientific qualifications and research experience relevant to the Institute's work. The post is graded Chief Scientific Officer and it is the Government's intention that the salary for this grade will be £13,908 per annum from April 1979 and £14,770 from April 1980.

Applications, including the names of three referees, should be received by February 16, 1979 and should be addressed to the Secretary, The Animal Virus Research Institute, Pirbright, Woking, Surrey GU24 0NF, from whom further particulars can be obtained. 8620(A)

UNIVERSITY OF OTAGO

Faculty of Medicine

The Christchurch Clinical School of Medicine

Christchurch, New Zealand

LECTURER OR SENIOR LECTURER IN MEDICINE

Applications are invited from medical graduates for the position of Lecturer or Senior Lecturer in the Department of Medicine in the Christchurch Clinical School of Medicine.

Applicants should have special clinical and research experience in the field of gastroenterology. Specific enquiries should be addressed to Professor D. W. Beaven, Department of Medicine, The Princess Margaret Hospital, Christchurch, New Zealand.

Salary: Lecturer NZ$14,673 to NZ$ 17,700; Senior Lecturer NZ$19,986 to NZ$25,729 per annum. A particularly well qualified applicant could be appointed with the status of Associate Professor NZ$27,026 to NZ$30,728. An allowance for clinical responsibility may be available in the light of status and duties performed.

Further particulars are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **February 15 1979.** 8632(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GENETICS

Applications are invited for the post of postdoctoral Senior Research Assistant to work with Dr P. Strike on an MRC-funded research project studying the enzymology of DNA repair processes in the bacterium *Escherichia coli.* Applicants should have experience in enzyme isolation and/or DNA metabolism. The area being investigated concerns the identification and characterisation of gene products concerned with resistance to DNA damaging agents in bacterial cells.

The project is financed for three years from January 1, 1979, or as soon as possible thereafter.

The initial salary will be £3,883 per annum (under review).

Applications, together with the names of two referees, should be received not later than December 18, 1978, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Reference: RV/405/N. 8606(A)

We have an immediate vacancy in the London office for a

PHYSICAL SCIENTIST

preferably one who has some postdoctoral experience. He or she would be engaged largely in the assessment of scientific manuscripts submitted for publication but would probably also help with other sections of the journal. Experience in the earth, ocean or atmospheric sciences would be an advantage.

Write to:
The Editor
NATURE
MACMILLAN JOURNALS LIMITED
4 Little Essex Street, London WC2R 3LF
enclosing a curriculum vitae and any other material you consider relevant.

8661(A)

DEAN
COLLEGE OF SCIENCE AND MATHEMATICS
UNIVERSITY AT ALBANY

Applications and nominations are invited for the position of Dean of the College of Science and Mathematics, University at Albany. The College consists of Departments of Atmospheric Sciences, Biology, Chemistry, Computer Science, Geological Science, Mathematics and Statistics and Physics. The College includes about 160 faculty, 350 graduate students and 1,100 upper division undergraduates. The Dean is the principal administrative and academic member of the College. His/her essential role is to provide intellectual leadership and direction for the instructional and research programs of the College.

Desired qualifications include an earned doctorate, proven scholarly ability and professional competence, appropriate academic and administrative experience, and the ability to provide creative leadership.

Applications and nominations with resumes should be sent by January 31, 1979, to:

Dr John F. Dewey, Chairman
Dean Search Committee
E.C.C. — LC B31
State University of New York at Albany
1400 Washington Avenue
Albany, NY 12222

The University at Albany is an Equal Opportunity/Affirmative Action employer. Applications from women, minorities, and handicapped are especially welcomed. 8612(A)

UNIVERSITY OF OXFORD
UNIVERSITY LECTURESHIP IN ORGANIC CHEMISTRY

Applications are invited for the above post. Stipend according to age on the scale (under review) £3,883 to £8,257. The successful candidate may be offered a tutorial fellowship by St. Hilda's College (for a woman) or Exeter College (for a man).

Details of the university and college appointments may be obtained from Professor J. E. Baldwin, F.R.S., Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, to whom completed applications (six typed copies, only one from overseas candidates) should be sent by January 31, 1979. 8588(A)

GRADUATE RESEARCH Assistant required for two years to join team investigating purine metabolism in gout. The work involves the measurement of purine nucleotides and related compounds in food, the effect of these compounds on uric acid metabolism in gouty patients and the monitoring of gout subjects attending the hospital out-patient departments. Good basic practical knowledge of chemistry essential, experience of automated analysis, electrophoresis of H.P.L.C. desirable. Salary not less than £3,409 plus £450 London Allowance. Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting reference P.M.1. 8648(A)

SOUTHAMPTON HEALTH SERVICES
MEDICAL LABORATORY SCIENTIFIC OFFICER

For the Department of Chemical Pathology and Medicine, Southampton General Hospital, to assist in a two year research study of cyclic nucleotide and phosphodiesterase changes in human liver disease and malignancy. Experience in radioimmunoassay and enzymatic methods would be an advantage. This post would ideally suit a Science Graduate wishing to complete one year as a Junior M.L.S.O. to qualify for state registration. Commencing salary: State registered £3,261 Junior M.L.S.O. £3,015. Application forms and job description from Personnel Department, Tremona Court, 30/32 Tremona Road, Southampton. Telephone Southampton 777222, ext. 3556.

Closing date December 14, 1978.
8595(A)

UNIVERSITY OF GLASGOW
RESEARCH ASSISTANT

Applications are invited for the post of research assistant in the University Department of Pathology, Western Infirmary, Glasgow G11, to undertake studies on immunological aspects of alcoholic liver disease. Applicants should have a good honours degree in one of the biological sciences and may apply to study for a postgraduate degree with this appointment. The appointment will be for three years and will be superannuated.

Salary will be within £3,384 to £3,883 on Range IB of the salary scale for Research and Analogous Staff.

Applications with the names of two referees should be submitted to Professor R. N. M. MacSween at the above address.

In reply please quote Ref. No. 4316M. 8607(A)

UNIVERSITY OF OXFORD
DEPARTMENT OF HUMAN ANATOMY
TECHNICIAN Grade IV
Salary £2,955 to £3,402 p.a.
(under review)

A technician is required to assist with histology and immunocytochemistry and maintenance of a laboratory. Work is in connection with brain research. Knowledge of the cryostat and stereotaxic techniques would be an advantage. The appointment is for a fixed term ending July 31, 1981.

Applications marked 'AC' should be made in writing without delay together with the names and addresses of two referees to The Adminstrator, Department of Human Anatomy, South Parks Road, Oxfrod OX1 3QX.

8650(A)

GUY'S HOSPITAL MEDICAL SCHOOL
Graduate *or* Postdoctoral Research Assistant

required in Physics Department for two years to work with Professor S. J. Wyard on a research project funded by the Medical Research Council, on the deformability of red blood cells.

Initial salary up to £4,407 plus £450 London Allowance, according to qualifications and experience.

Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. P.T.1.

8603(A)

SCUOLA NORMALE SUPERIORE
Pisa, Italy

Postdoctoral Position in Theoretical Physics is offered for a period of 10 months from October 1, 1979, for research in one of the fields: astrophysics, plasma physics, particle physics, and field theory.

The total salary attached to this position is seven million Italian lire. Successful candidates may apply for a partial reimbursement of travel expenses.

Applications should be sent by March 31, 1979, to the Director of the Scuola Normale Superiore, Piazza dei Cavalieri, Pisa, Italy, and should enclose a curriculum vitae, a detailed programme of study, and letters from three referees. 8584(A)

IMPERIAL COLLEGE
University of London
LECTURESHIP IN DEPARTMENT OF PHYSICS

Applications are invited for the post of Lectureship to work in the Atmospheric Physics Group, under the general direction of Dr J. S. A. Green. Salary on the scale £3,883 to £7,754 (under review) with superannuation plus London Allowance of £450 per annum.

Applications with curriculum vitae, list of publications and the names of two referees should be addressed to Professor D. J. Bradley, F.R.S., Head of Department, Blackett Laboratory, Imperial College, London SW7, before January 10, 1979. 8613(A)

STRUCTURAL BIOLOGIST

The Department of Biological Sciences, Carnegie-Mellon University, invites applications from individuals whose research interests include the use of biochemical and biophysical techniques to study biological structures. The candidate should have postdoctoral experience. The position is at the assistant or associate professor level. Responsibilities include teaching at the undergraduate and graduate level, and carrying out an active research program. The applicant should forward a **curriculum vitae, three or** more letters of reference, and a brief résumé of research plans to Search Committee (B), Department of Biological Sciences, Carnegie-Mellon University, 4400 Fifth Avenue, Pittsburgh, PA 15213, U.S.A.

Carnegie-Mellon University is an Equal Opportunity/Affirmative Action Employer. Please respond by December 15, 1978. 8446(A)

GUY'S HOSPITAL MEDICAL SCHOOL
LABORATORY SCIENTIFIC OFFICER

required until September 30, 1980, to work in the Department of Chemical Pathology. Duties will include the *in vitro* cultivation of malaria parasites. Previous experience in tissue culture techniques essential. Salary for qualified Laboratory Scientific Officer not less than £3,261 plus £354 London Weighting.

Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. C.H.1. 8602(A)

SCIENTIFIC DIRECTOR

Biological Sciences: c. £9,500

Flow Laboratories, a leader in the supply of tissue cultures, reagents, and laboratory equipment, is appointing a European Scientific Director to work from its West of Scotland headquarters. Responsibilities will include contact with the scientific community, research and product development, quality control and the organisation of educational seminars. The Europe wide role will bring the Director into frequent contact with customers throughout the continent. Candidates, probably in their 30s, will be Ph.D.s with detailed up to date experience in virology, microbiology, bacteriology, biology or immunology. They will have an ability to communicate as well with the layman as with the scientist and should see themselves fitting naturally into a strictly commercial environment. Salary is negotiable and together with an annual bonus will be around £9,500. Executive car and other benefits appropriate to this level of seniority. Relocation expenses. Applications with full career details from men and women should be sent in confidence to A. P. Rait, as adviser to the company, at Selection Thomson Ltd., 15 North Claremont Street, Glasgow G3 7NR.

8605(A)

SELECTION ● THOMSON

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Biophysical chemist required to join research group working on membrane structure and function Initial salary within range £3,909 to £4,655 p.a. plus £450 London Allowance.

Further particulars available from the School Secretary, R.F.H.S.M., 8 Hunter Street, London WC1N 1BP or telephone 01-837 5385, ext. 54 Closing date December 15, 1978 8601(A)

UNIVERSITY OF EAST ANGLIA

Norwich

LECTURESHIP IN ORGANIC CHEMISTRY

Applications are invited for the above Lectureship in the School of Chemical Sciences Salary according to age and experience, will be on the scale £3,883 to £7,754 per annum (under review) plus U.S.S./F.S.S.U. benefits.

Applications (one copy only) which should contain a full curriculum vitae including exact date of birth, together with the names and addresses of three persons to whom reference may be made, should be lodged with the Establishment Officer, University of East Anglia, Norwich NR4 7TJ, from whom further particulars may be obtained (telephone 0603 56161, ext. 2126) by not later than February 1, 1979. No forms of applications are issued In naming three referees you are requested to give only the names of those who can immediately be approached by the University

8590(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF CHILD HEALTH

RESEARCH ASSISTANT

Post-doctoral scientist or equivalent with experience in electron microscopy, immunology and/or autoradiography to work on immediate hypersensitivity in the lung The position, which is on the salary scale Range 1A for research staff £3,883 to £6,555 per annum (under review) is funded by the Wellcome Trust and is available immediately.

Applications with a curriculum vitae and two referees to Dr F. Carswell, from whom further information is obtainable, Department of Child Health, Children's Hospital, Bristol BS2 8BJ. 8586(A)

WELSH NATIONAL SCHOOL OF MEDICINE

(University of Wales)

LECTURER IN MEDICAL BIOCHEMISTRY

Applications are invited from science graduates with or without a medical qualification, for the post of Lecturer in the Department of Medical Biochemistry at the Medical Teaching Centre, Cardiff. The Department is engaged in teaching both medical and science students and has good facilities for research

Salary either on the scale £4,470 to £7,793 per annum for clinical Lecturers or £3,883 to £7,754 per annum for non-clinical Lecturers (both inclusive or supplements)

Applications should be submitted within four weeks of the appearance of this advertisement to the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN, from whom further particulars may be obtained. 8587(A)

UEA

NORWICH

VICE-CHANCELLOR

The Council and Senate of the University of East Anglia have appointed a Joint Committee to recommend a successor to the Vice-Chancellor, Dr. Frank Thistlethwaite who retires on September 30, 1980.

The Committee invites applications for the post. Persons with appropriate qualification and experience may write privately to the Chairman of the Committee (the Pro-Chancellor and Chairman of the Council, Mr. T. J. A. Colman) care of the Registrar and Secretary, University of East Anglia, if possible no later than the middle of January 1979.

The Committee would also welcome suggestions of the names of persons suitable for consideration and these should similarly be addressed to the Pro-Chancellor.

The Council reserves the right to appoint to the post by invitation.

Information about the University and further particulars of the post may be obtained from the Registrar and Secretary, University of East Anglia, The Registry, Norwich NR4 7TJ.

8598(A)

POSTDOCTORAL RESEARCH POSITION

The Department of Geology, University of Windsor, invites applications for a one-year appointment commencing February-April, 1979. Qualifications: a Ph.D in sedimentology with a basic knowledge of glacial geology, or a Ph.D. in glacial geology with a basic knowledge of sedimentology Stipend $925 per month

Send curriculum vitae and names of three referees to: Dr R. K Jull, Head, Department of Geology, University, Windsor, Ontario, Canada N9B 3P4. 8636(A)

POSITION AVAILABLE

for young Ph.D in biochemistry interested in working on the comparative protein chemistry of the major structural proteins of higher cells Experience in sequence analysis or protein chemistry would be helpful The group is bilingual.

Salary according to experience (not less than DM1,900=~$1,000 or £512 per month tax free).

Application to Klaus Weber, Max Planck Institute for Biophysical Chemistry, D-34 Gottingen, West Germany.

8566(A)

MEDICAL RESEARCH COUNCIL
LABORATORY OF MOLECULAR BIOLOGY
RESEARCH ASSISTANT

required in January 1979 to join a group working on chemical aspects of peptide and oligonucleotide synthesis. Candidates should possess a degree or equivalent qualification in chemistry, biochemistry, or a related science subject. Initial salary on the scale £3,261 (£4,680) with good prospects for promotion to research officer grade and permanency.

Applications giving details of qualifications, experience, and names of two referees, should be sent to me at this address as soon as possible

Dr R. C Sheppard,
MRC Laboratory of Molecular Biology,
The Medical School,
Hills Road,
Cambridge CB2 2QH. 8581(A)

MEDICAL RESEARCH COUNCIL
RADIOBIOLOGY UNIT
CYTOGENETICS

A vacancy exists for a scientist to work in a group investigating the effects of ionising radiation upon chromosomes in a variety of cells and tissues

Applicants should have a good honours degree, and at least three years' post-graduate research experience. They should be conversant with modern cytogenetic techniques and some knowledge of tissue culture is desirable.

Usual Medical Research Council conditions of service Salary according to age and qualifications Applications in writing to: The Administrator, M R C, Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD. By December 31, 1978 8622(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post-doctoral post of Senior Research Assistant to participate in investigations into mutagenic DNA repair systems in mammalian cells The appointment is funded by the Cancer Research Campaign and is tenable until September 30, 1981

Initial salary within the range £3,384 to £4,382 per annum, depending on age and experience

Applications, together with the names of two referees should be received as soon as possible by The Registrar, The University, P O Box 147, Liverpool L69 3BX, from whom further particulars may be obtained Quote Ref RV/406/N 8623(A)

COURSES

FEBS ADVANCED COURSES

No. 58, "Biomolecular Electron Microscopy"
Ulm, FRG,
29 March—7 April 1979

The Course, organized by A K Kleinschmidt, is intended to offer information on selected methods of biomolecular structure studies, and laboratory instruction in electron-microscopic methods of macromolecular analysis, to 40 qualified applicants Specialised fields, e.g electron microscopy of nucleic acids, membrane structure, nucleoprotein particles, immunocytochemistry, lipoproteins and proteoglycans, and autoradiographic procedures and image analysis methods will be included to participants' choice in laboratory practical sessions. Course fee, including accommodation and food: approx. DM400 — Applications (by 1 January, 1979) and info· Dr A K Kleinschmidt, University of Ulm, Department of Microbiology, Postfach 4066, 7900 Ulm, FRG

No. 60. "Gene Structure and Formation of RNA of Viruses and Animal Cells"
Israel, 15—21 May 1979

A workshop organized by Y Aloni and co-sponsored by EMBO Fee: $280 — Info: Mr Y Berman, Congress Section, Weizmann Institute of Science, Rehovot, Israel.

No. 62. "Genome Organisation and Expression in Higher Plants"
Edinburgh, Scotland,
11–21 July 1979

A course for up to 125 participants Accommodation including full board, £120 approx. Info. Dr C. Leaver, Dept of Botany, The King's Buildings, Mayfield Road, Edinburgh, EH9 3JH, Scotland.

No. 56. "Membrane Proteins"
Berne, Switzerland,
10–22 September 1979

The course, co-sponsored by the Swiss Committee for Molecular Biology and organized by P Zahler and A Azzi, will consist of 1 week each of lectures and experimental work, and discussions The course will concentrate on specific problems of membrane proteins (solubilization, fractionation, isolation, characterization, reconstitution) Places will be restricted to 80–100 for the lectures and to 40 advanced participants for the experimental part. Fees (including registration, accommodation and food): Sw Fr 700 —for the full course or Sw Fr 340 —for the lecture course only Applications should be addressed before 1 April, 1979 to: Professor P Zahler, Institut fur Biochemie, Universität Bern, Freiestrasse 3, CH-3012 Bern, Switzerland.

No. 57. "Genetic Engineering"
Zagreb, Yugoslavia,
8–24 October 1979

Info: Dr V. Škarić, Institut "Ruder Bošković", Pošt, pret 1016, 41001 Zagreb, Yugoslavia. 8583(D)

UNIVERSITY OF LONDON KING'S COLLEGE
INTERCOLLEGIATE COURSE
M.Sc.
IN
HUMAN AND APPLIED PHYSIOLOGY

A one year course to train graduates in measuring and studying the physiological functioning of man in normal and abnormal environments. The course would equip students to specialise in the applications of physiology to man in industrial, Service and clinical situations and the teaching of human physiology Topics studied include·—basic measurements, life support systems, exercise; locomotor, postural, climatic, high altitude and hyperbaric physiology.

October 1, 1979 to September 30, 1980.

Applicants should normally have a good degree in Physiology or be medically qualified

Further details and application form from Dr S Rowlands, King's College, Strand, LONDON WC2R 2LS, quoting reference 191653/N

Closing date for applications March 31, 1979 8654(D)

N A T.O. ADVANCED STUDIES INSTITUTE— F.E.B.S. WORKSHOP
GENOME ORGANISATION AND EXPRESSION IN PLANTS
July 11–21, 1979, Edinburgh Scotland

This workshop will be concerned with the organisation and expression of the nuclear and organellar genomes, regulation of gene expression, macromolecular properties, biosynthesis and genetic regulation of seed storage proteins; plant viruses, plasmids and viroids

Speakers will include. W. F Thompson (Stanford), J Bedbrook (Cambridge), R. Meagher (Athens, Georgia), R Flavell (Cambridge), P Starlinger (Koln), K Murray (Edinburgh), J. Jendrisak (Minnesota), J. Bishop (Edinburgh), L Dure (Georgia), K Hahlbrock (Freiburg), D. P S Verma (McGill), L N. Vanderhoef (Illinois), G Blobel (Rockerfeller), B Larkins (Purdue), T C Hall (Wisconsin), L Bogorad (Harvard), R. J Ellis (Warwick), J H. Weil (Strasbourg), O. Ciferri (Pavia), F Quetier and F Vedel (Orsay), C J. Leaver (Edinburgh), L Hirth (Strasbourg), Louis Van Vloten-Doting (Leiden), J Schell (Ghent), Mary-Dell Chilton (Seattle), J Kemp (Madison, Wisconsin), H. L Sänger (Giessen), R Dixon (Sussex)

The number of speakers and participants will be strictly limited to 125 and everyone will be expected to attend for the duration of the workshop

Applications with a short curriculum vitae, including present scientific interests and information which might help in their evaluation (e g a letter of recommendation, where appropriate) should be sent in duplicate to Dr C J Leaver, University of Edinburgh, Department of Botany, The King's Buildings, Mayfield Road, Edinburgh EH9 3JH to arrive *not later* than February 14, 1979

Successful applicants will be informed as soon as possible and expected to provide a non-refundable deposit of £25 (which will be deducted from the living expenses of approximately £130). A limited number of grants, to cover partially the living expenses and travel costs, are available but participants are encouraged to cover their expenses from the resources of their own institutions wherever possible. 8592(D)

UNIVERSITY OF SURREY
DEPARTMENT OF MICROBIOLOGY
M.Sc. COURSE IN MEDICAL MICROBIOLOGY

A new, two-year part-time (day release) course in advanced medical microbiology will start in October, 1979 The course is designed mainly for graduates with some experience of working in a medical microbiology laboratory.

For further details, contact the course organiser.

Dr J W Dale,
Department of Microbiology,
University of Surrey,
Guildford, Surrey, OU2 5XH
Tel Guildford 71281, ext 871.
8656(D)

THE UNIVERSITY OF MANCHESTER
Diploma in Bacteriology

Applications are invited for admission to the Diploma in Bacteriology course of one academic year in the session 1979/80 The course is designed to give training and experience in aspects of bacteriology and animal virology which are of general importance in the application of the subject to different specialised fields. Applicants must have qualified in medicine, veterinary medicine, or other branches of science, and have had substantial postgraduate practical experience in bacteriology Medical Research Council awards may be available to suitably qualified British Subjects resident in the United Kingdom Forms of application may be obtained from the Department of Bacteriology and Virology, University of Manchester, Stopford Building, Manchester M13 9PT, and should be returned as soon as possible, and in any case not later than February 1, 1979 8599(D)

STUDENTSHIPS

UNIVERSITY OF SURREY
DEPARTMENT OF BIOCHEMISTRY
S.R C C A S.E. STUDENTSHIP

Applications are invited for a CASE Studentship financed by S.R.C. in collaboration with Shell Toxicology Laboratory, Sittingbourne, Kent, tenable for three years and for work on Molecular studies of the fidelity of DNA repair

Applicants must have upper second or first class honours in Biochemistry or a related subject.

Applications with curriculum vitae and the names and addresses of two referees should be sent to Dr L J King before December 8 For further details, interested applicants are asked to telephone:

Dr King,
Department of Biochemistry,
University of Surrey,
Guildford GU2 5XH
Tel. Guildford (0483) 71281,
Extension 499 8651(F)

MEDICAL RESEARCH COUNCIL
National Institute for Medical Research
DIVISION OF BIOCHEMISTRY

A Medical Research Council Research Studentship is immediately available for work towards a Ph.D. degree with Dr I M Kerr on the mechanism of action of interferon and the control of protein synthesis in animal virus infected cells. The role of interferon-mediated protein kinases and the oligonucleotide effector pppA2'p5'A2'p5'A in these systems and in growth control in normal and transformed cells will be investigated

Applicants must have a first or upper second class honours degree in Biochemistry or a related subject and be available to take up the Studentship almost immediately.

Please apply, including a *curriculum vitae*, as soon as possible to Dr J B Ward, Director of Studies, National Institute for Medical Research, London NW7 1AA (closing date Monday, December 11, 1978) 8642(F)

ASSISTANTSHIP

IMPERIAL COLLEGE
DEPARTMENT OF ZOOLOGY

Applications are invited for a postdoctoral Research Assistantship tenable at the College Field Station for work for three years on a Medical Research Council sponsored project on the sexual development of malarial parasites. The successful applicant will be expected to develop new methods for the culture and purification of the parasite, and to study the biochemistry/physiology of the parasite plasmalemma. Experience in the fields of cell fractionation of membrane chemistry would be an advantage.

Salary in the range £3,883 to £4,631 on the Research and Analogous Staff scale, plus U.S.S.

Applications with the names of two referees in writing by December 15, to Dr R. E. Sinden, Imperial College Field Station, Ashurst Lodge, Ascot, Berks. 8604(P)

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF CHEMISTRY

Postdoctoral Research Assistantships in Molecular Beam Scattering

Applications are invited for two post-doctoral research assistantships supported by S.R.C. in the research group of Professor R. Grice, to study (a) molecular beam reactive scattering or (b) molecular beam studies of reactions of aeronomic importance. The work involves the measurement of reactive scattering with universal molecular beam machines employing mass spectrometric detection and time-of-flight analysis. Experience in reaction kinetics and vacuum technology would be an advantage.

Initial salaries up to £4,382 p.a. and £4,631 p.a. respectively with appointments for one year in the first instance. Superannuable.

Applications (no forms) to the Registrar, University of Manchester, Manchester M13 9PL, enclosing a curriculum vitae and the names of two referees. Closing date December 20. Quote Ref: 261/78/N. 8609(P)

FELLOWSHIPS

UNIVERSITY COLLEGE DUBLIN
POSTDOCTORAL FELLOWSHIP IN PHYSICAL CHEMISTRY

Applications are invited for a postdoctoral fellowship to investigate the use of circularly polarized light in photochemistry. Applicants should have practical experience in optical and electronic techniques of photochemistry or molecular spectroscopy.

The appointment which is supported by the National Board of Science and Technology, will be made as soon as possible for one year at an initial salary of £3,762 (for newly qualified Ph.D.'s), and may be extended to three years.

Applications, accompanied by a curriculum vitae and the names of two referees, should be sent to:

Dr. Hector Rubalcava,
Department of Chemistry,
University College,
Dublin 4, Ireland. 8637(E)

INVERTEBRATE NEUROBIOLOGY
RESEARCH FELLOWSHIP

available for 2–3 years to study molecular mechanisms involved in control of electrical properties of molluscan neurones. Experience with intracellular recording (preferably in *Aplysia*) required.

CV and three letters of recommendation to: Dr. I. Levitan, Friedrich Miescher-Institut, P.O. Box 273, Ch-4002 Basel, Switzerland. 8643(E)

UNIVERSITY OF WARWICK
POSTDOCTORAL FELLOW IN VIROLOGY

Applications are invited for a Postdoctoral Fellowship with the Virus Research Group in the Department of Biological Sciences. The successful applicant will work in a small group studying the role of defective interfering virus in infections of animals. An interest in fundamental aspects of pathogenesis and a background in virology or immunology is desirable.

The post is for three years, commencing as soon as possible, and is funded by the Medical Research Council. Starting salary will be on the first point of the Research 1A scale, £3,883 (under review). Further details and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 17/A/78.

Closing date for receipt of applications is December 22, 1978. 8647(E)

UNIVERSITY OF EXETER
DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Fellowship supported by the Medical Research Council, to work in collaboration with Dr D. H. G. Crout and with Mr R. S. M. Ling, F.R.C.S., of the Princess Elizabeth Orthopaedic Hospital, Exeter, on the metabolism of methyl methacrylate in man. This project is part of a programme in which various aspects of the use of polymethylmethacrylate in Orthopaedic Surgery are under investigation. The research will involve the use of combined gas-chromatography-mass spectrometry. Previous experience of this technique would be desirable though not essential.

The appointment will be for two years, starting as soon as possible. Commencing salary will be £3,883 per annum, rising to £4,133 per annum for the second year of the appointment.

Applications, giving details of age, qualifications and experience, together with the names of two referees should be sent as soon as possible to Dr D. H. G. Crout, Department of Chemistry, Stocker Road, Exeter AX4 4QD. 8621(E)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF VETERINARY PHYSIOLOGY

POSTDOCTORAL RESEARCH FELLOWSHIP
(Scale IA: £3,883 to £6,555 per annum)

Applications are invited for the above post, which is supported by an M.R.C. Programme Grant to Dr A. G. Brown, tenable for five years from January 1, 1979. The Fellow will join a team studying the electrophysiology, ultrastructure and quantative morphology of identified spinal cord neurones. The Fellow will be responsible for computer graphics analysis of neuronal structure. He or she will need to be conversant with computer technology, graphics systems, programming and electronics. An interest or experience in neurobiology would be desirable. A Joyce-Loebl MAGISCAN image analysis system containing a NOVA 3/12 computer will be available.

Applications, including the names and addresses of two referees, should be sent as soon as possible to Dr A. G. Brown, Department of Veterinary Physiology, University of Edinburgh, Summerhall, Edinburgh EH9 1QH. Please quote Reference 5070.

8640(E)

BRITISH DIABETIC ASSOCIATION
LAWRENCE RESEARCH FELLOWSHIP
SUBJECT: DIABETES MELLITUS

ELIGIBILITY: Open only to UK residents. Candidates must be appropriately qualified in medicine or science. VALUE: Appropriate point on NHS or university scale up to registrar or equivalent university) grade. TENABLE: In any approved institution in UK, for 2 years. OTHER INFORMATION: Awarded for independent research. NUMBER: Two offered, normally every two years. (Offered for 1979/80.) PARTICULARS: Available from Secretary-General, British Diabetic Association, 10 Queen Anne Street, London W1M 0BD. Tel: 01-323 1531.

CLOSING DATE: December 20, 1978. 8657(E)

THE ROYAL SOCIETY
BRUNO MENDEL FELLOWSHIPS

Applications are invited for Bruno Mendel Fellowships for one year from October 1, 1979, renewable for one and exceptionally two additional years, from postgraduate candidates normally resident in the United Kingdom, The Netherlands or Israel, to carry out research in medicine or the biomedical sciences at a university, medical research centre or medical school. Stipends will normally be at the level of a junior research fellowship appointment in the United Kingdom; additional allowances for travel and superannuation may be provided as appropriate.

Application forms, receivable by January 15, 1979, and regulations (revised in May 1976) are available from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. 8611(E)

UNIVERSITY OF SOUTHAMPTON
SCHOOL OF BIOCHEMICAL AND PHYSIOLOGICAL SCIENCES

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a Wellcome Trust supported appointment for two years as a postdoctoral research fellow investigating the causes of *oedema in pregnancy*. Candidates should have experience and an interest in endocrinology, salt and water balance, thirst and salt appetite or cardiovascular physiology. The successful applicant will enjoy working with animals and will be able to initiate and conduct his/her own research, within the limits defined by the grant.

The appointment is initially for one year, renewable for a further year, and can commence in January 1979.

Salary: £3,883 per annum for Year 1; £4,133 per annum for Year 2 (under review). U.S.S. benefits. Please write for further details to Dr P. Burstyn, School of Biochemical and Physiological Sciences, Boldrewood, Southampton.

Applications giving date of birth, details of qualifications and experience and the names and addresses of two referees, should be sent to Mrs. P. Vaughan-Smith, The University, Southampton SO9 5NH by December 15, 1978. Please quote ref: 1041/R/N.

8591(E)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF AERONAUTICS AND ASTRONAUTICS

RESEARCH FELLOWSHIPS *or* ASSISTANTSHIP IN COMBUSTION

Applications for the above post are invited from suitably qualified engineers or scientists to take part in a fundamental, experimental and theoretical research programme, funded by the United States Air Force, to assist development of new types of combustion chamber for propulsion systems. The appointment would be for one year in the first instance but it is hoped that the research programme will continue for a further period.

Salary will be within range 1A or 1B up to £4,631 per annum (under review) plus U.S.S. benefits.

Applications giving a brief curriculum vitae and the names of two referees should be sent by December 8 to D. A. S. Copland, The University, Southampton SO9 5NH, from whom further particulars may be obtained. Please quote reference 176/R/NSc. 8600(E)

CONFERENCES

24th OHOLO BIOLOGICAL CONFERENCE
on
NEUROACTIVE COMPOUNDS AND THEIR CELL RECEPTORS
on
1st to 4th APRIL, 1979
at
ZICHRON YA'ACOV
ISRAEL

Applications and further information from: Mrs Ariela Snir, Secretary to the Oholo Conference, Israel Institute for Biological Research, P.O. Box 19, Ness-Ziona, Israel.

Invited Papers Only.

INTERNATIONAL CONFERENCE
and POSTER PRESENTATION on
ELECTROKINETIC PROPERTIES AND FUNCTIONS OF BIOPARTICLES
MARTINSRIED near MUNICH, GERMANY
OCTOBER 13–19, 1979

Topics: Dynamics of cell membranes; Surface proteins: changes during cell growth and transformation; Assembly and turnover of subcellular structures; Analytical cell electrophoresis and its application in clinical diagnosis.

Information: Professor Dr Kurt Hannig
Max-Planck-Institut für Biochemie
8033 Martinsried, Germany 8658(C)

A MEETING ON RECOMBINANT DNA

Organized by the Committee on Genetic Experimentation (COGENE), of the International Council of Scientific Unions and the Royal Society of London and will be held at Wye College Kent from 1-4 April 1979. The purpose of the meeting is to review the current status of recombinant DNA research and technology and to discuss matters of concern such as support for the research, its regulation through guidelines and legislation, and the eventual practical application of the technology.

Representatives of national recombinant DNA committees and other involved national and international organizations are being invited but a small number of places are being reserved for general applicants.

The registration fee for the Conference is US $80 or £40.
The charge for accommodation and full board is US $120 or £60.

Those wishing to participate should write for a registration form and further details to The Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, England.

NEW PRODUCTS FOR RNA SEQUENCING

RIBONUCLEASE PHY I
(RNase I from Physarum polycephalum)

This novel enzyme preferentially digests G, A and U residues, allowing discrimination between C and U in RNA sequencing methods (1,2). This makes possible sequencing of terminally labeled RNA by the gel method (2).

One arbitrary unit gives partial digestion of 1 microgram of RNA under conditions described in ref. (2).

Cat. No. ERN-PHY $145.00/100 units

(1) Gupta, R., and Randerath, K. (1977). Nucleic Acids Res. 4, 3441
(2) Simoncsits, A., Brownlee, G. G., Brown, R. S., Rubin, J. R., and Guilley, H. (1977). Nature 269, 833.

T4 POLYNUCLEOTIDE KINASE (RNase-free)

Prepared from T4-infected RNase⁻ *E. Coli B* specifically labels 5′-OH termini of RNA and DNA chains. With this product, kinase labelling of small quantities of large RNA's for sequencing is possible for the first time.

Cat. No. EPN-4 $68.00/100 units $255.00/500 units

T4 RNA LIGASE (RNase-free)

The enzyme is capable of adding single residues (in the form of pNp) to 3′ termini of the RNA chains, allowing sequence analysis by the gel method. Ligase from RNase⁻ *E. Coli B* allows application of this approach to a variety of large RNA species.

Cat. No. ERL-4 $60.00/100 units $235.00/500 units

British Birds

Cloning Reagents from BRL

Terminal Transferase - T4 DNA Ligase

Regardless of how you construct your plasmid chimaera, BRL terminal transferase and DNA ligase are guaranteed to get the job done.

BRL's T4 DNA ligase has excellent activity for joining blunt (base paired) ends of DNA—a rigorous challenge of ligation efficiency. For homopolymer "tailing" of duplex DNA, you can expect terminal transferase from BRL to add at least 50 residues dAMP or 200 residues dTMP per strand within 30 minutes (λ DNA ends).

BRL Terminal Transferase and T4 DNA Ligase: the reagents of choice for cloners the world over.

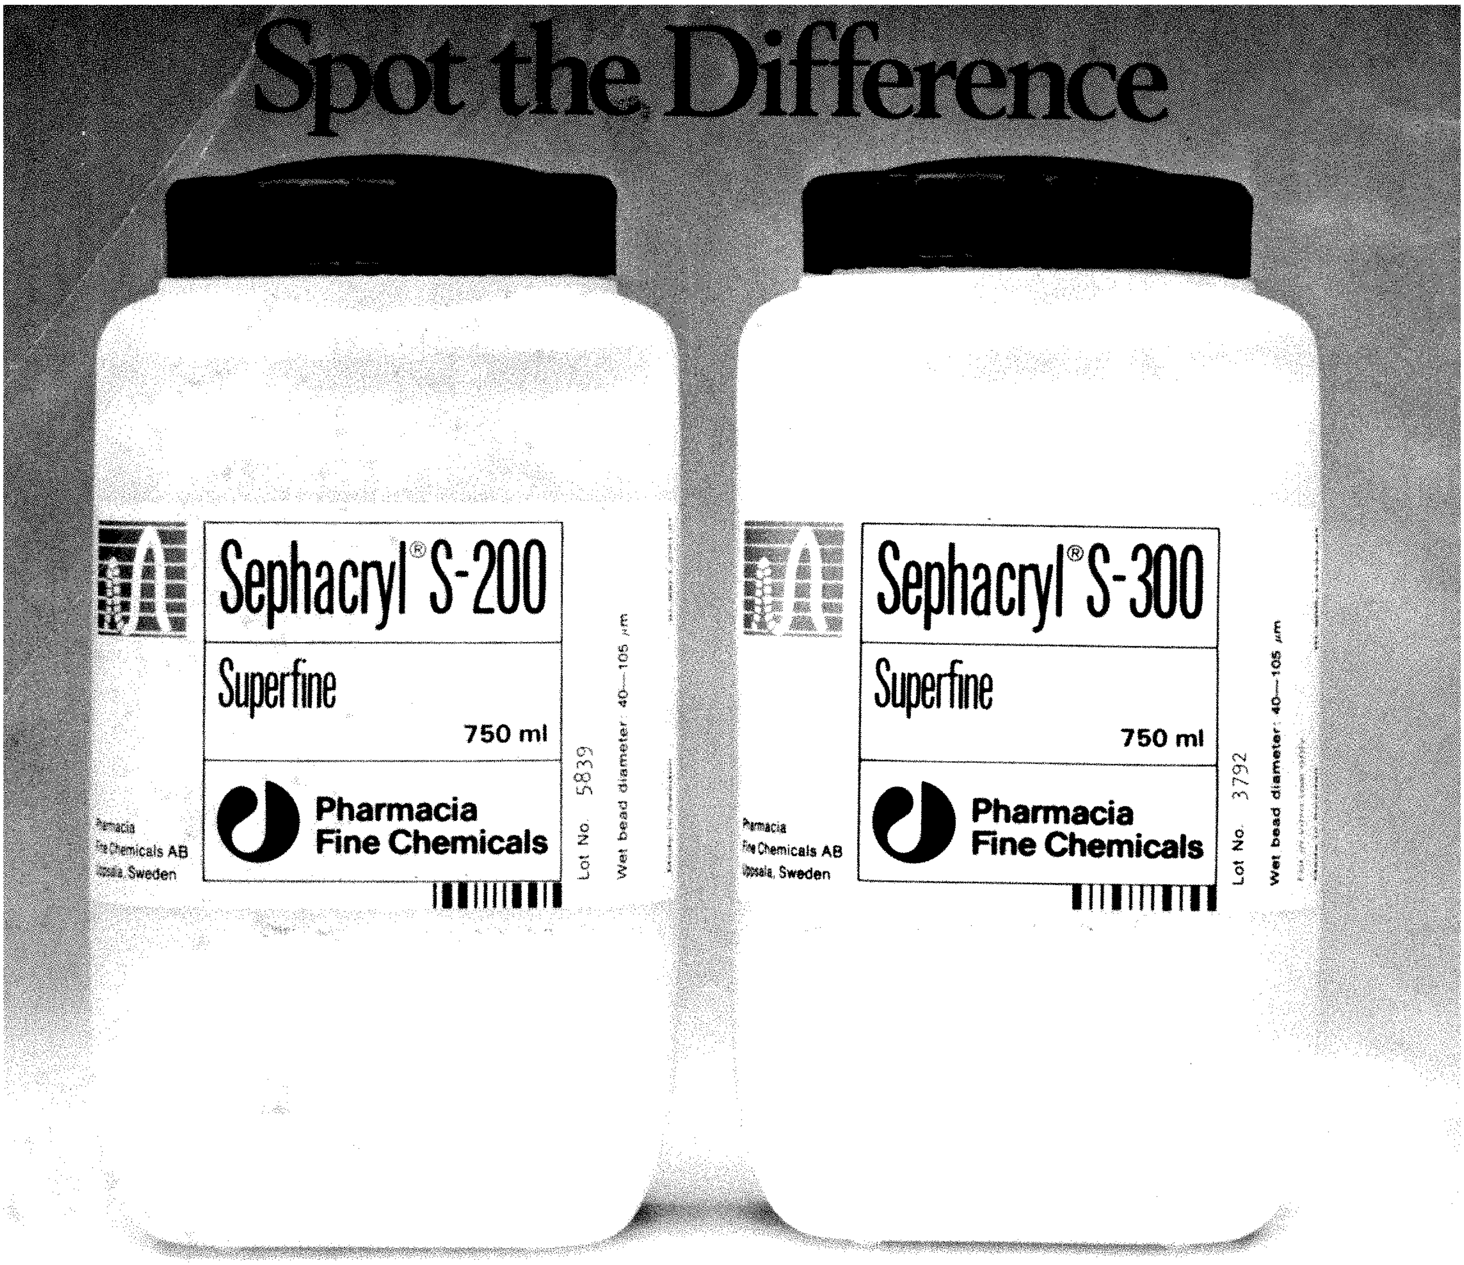
CHRISTMAS BOOKS



Sephacryl®

the different medium for gel filtration

- **Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.**
- **Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.**

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

Royal Society Esso Award for the Conservation of Energy

For the second consecutive year the Royal Society Esso Award for 1978 has been awarded to a group of five.

Due to their efforts in developing the Prototype Fast Reactor at Dounreay, the reactor has now been functioning safely and effectively since 1976. It has achieved a very notable increase in the efficient use of nuclear fuel and has a generating capacity equal, in one year, to that of 400,000 tons of oil.

The winners of the Award are Mr A. G. Frame, Mr J. M. Laithwaite, Mr A. D. Evans, Dr J. F. W. Bishop and Dr T. N. Marsham.

Previous awards have been made for work on corrosion in power stations, the development of an electronic system that computes optimum start and shut-down times for heating systems in individual buildings; work in the developing field of solar energy utilisation; and the application of gas turbines to total energy systems in industrial plants.

The Royal Society Esso Award for the Conservation of Energy was instituted in 1974 and consists of a gold medal and a prize of £1,000. It is awarded for outstanding contributions to the advance of science, engineering and technology leading to a more efficient conversion or use of any form of energy. Nominations for the 1979 Award are required by 7 February 1979. For further details, please contact:

The Executive Secretary,
The Royal Society,
6 Carlton House Terrace,
London SW1Y 5AG.

Circle No. 15 on Reader Enquiry Card.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

Genetic variability and population structure of *Poecilia latipinna* — *D. E. Simanek* 612

Arginine vasopressin maintains ethanol tolerance — *P. L. Hoffman, R. F. Ritzmann, R. Walter and B. Tabakoff* 614

Science has a word for it

" I'M SORRY, but arranging for you to see Dr Smith in the next few weeks is going to be very difficult; he's **delocalised** between London and Geneva". So said a scientist on the phone to us recently. The thought of the fairly ample Dr Smith being a mere probability density function and subjected to an uncertainty principle started a train of thought about how scientists could enrich or befoul the English language.

Some jargon has, of course, already made the jump, sorry the transition, from the laboratory to everyday use—for instance half-life. *Fall-out*, an undesirable consequence in its scientific context which became a desirable one in its general usage has got even further—to retirement. But there are riches untouched as yet, and others not well enough known. Here are a few examples.

world-line: 'If only I'd known you were in London yesterday, we could surely have made our world-lines intersect'. One way to have done this, of course, would have been to settle on a **time** and **space window.** That would have put up the **collision cross-section** by **orders of magnitude.**

hysteritic: Suitable as a descrption of management or bureaucracy. You push in one direction and you encounter resistance and delay; you reverse your direction of attack and lo and behold the self-same resistance and delay meets you.

boundary conditions: When you are looking around for a new job you specify certain requirements—rural environment, good schools in the neighbourhood, no overtime, easy access to London . . . In short, boundary conditions. A search through the classified advertisements then yields a set of suitable jobs consistent with them; presumably these are called **eigenfunctions.** The salaries, or **eigenvalues,** often bear a strong similarity to each other. This is hardly surprising given the nature of the world. But scientists even have a word for that: **degeneracy.**

boeing: Not strictly a scientific word, of course, but refers to the behaviour of many scientists. Many laboratories have one person who is always flying off to conferences. He is said to be boeing around. I bo, you bo, he boes; though of course you and I don't do it.

orthogonal: A slightly derogatory term. 'His interests are pretty orthogonal to mine' indicates that of all the wealth of my interests, he can't find a thing in common with me. Other stronger insults are to imply that a colleague has **limited bandwidth** or, what comes to the same thing, **high-Q**—a narrow view of the world and an ability to go on and on when given the chance. Nor is calling someone **non-linear** polite. It suggests that under pressure they either fade or over-react.

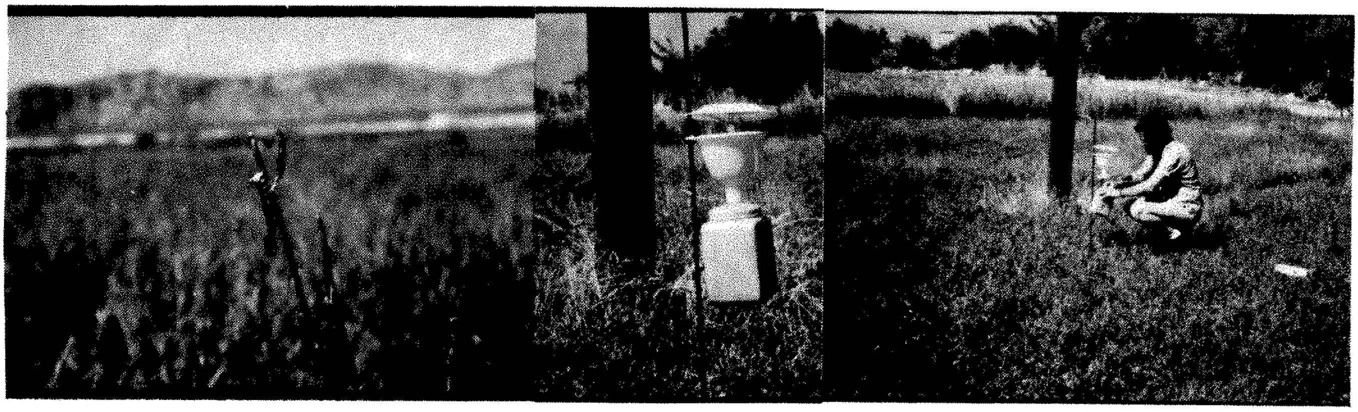
deconvolution: Ask a simple question and some people, with complex **transfer functions,** convert your **input** into highly convoluted **output.** Deconvolution is simply finding out whether they said yes or no. You may also have a **signal-to-noise ratio** problem to contend with.

perturbation: invariably associated with an order. A **first-order** perturbation is very large indeed, such as getting married, having children, changing jobs. A **second-order** perturbation is trifling; for instance picking up a colleague on the way to work, answering the phone for him when he's out of the room.

tunnelling: Every graduate physicist knows that there isn't a potential barrier so high that it can't be passed through by hanging around outside it long enough. So to 'tunnel' is to get where you don't belong simply by persistence. Hence 'I see that at long last Jones has tunnelled his way into The Royal Society, the professorship etc. It sounds quite polite, even creditable, and suggests a certain amount of beavering; preferable to talking of Buggins' turn.

Do not confuse tunnelling with the ability of Hungarians to enter a revolving door behind you and come out ahead of you. This is a genuine and quite simple skill, and science has a word for it, too; **spin-flipping.** Those subjected to it have been known to remark 'What's happening to this spin-flipping door?'

Christmas competition. Now that we have started you on the learning-curve, we would like to access your database of similar examples. £10 for the most outrageous entry received at *Nature*, 4 Little Essex St, London WC2 by 6 Jan.



UK investigates virus insecticides

Pathogenic insect viruses may be a safe and effective alternative to chemical insecticides. The Unit of Invertebrate Virology at Oxford and the Centre for Overseas Pest Research in London are already conducting field trials with one class of virus: Baculoviruses. **A. J. McClelland and Peter Collins** report

THE EARTH is dominated by insects: they are present in staggering numbers (a billion billion, according to one estimate) and they are found in every habitable part of the globe. There is a greater diversity of insects than of any other group of animals, and they occupy many different, but essential, ecological niches. Fortunately, only a tiny minority, about 0.1% of species, are harmful to humans. This, though, represents about 3,000 insect species which can cause an immense amount of damage. Insect pests are vectors for several human diseases and also responsible for reducing available food supplies in the world by about 30%. Controlling them is thus of paramount importance in a world where food supplies are often unable to meet human needs.

For the past 40 years, chemical insecticides have been the primary method of controlling insect populations. This is because chemical insecticides were cheap to manufacture, easy to apply and highly effective. By comparison, biological methods of control appeared to be ineffective and unpredictable. But it is now realised that chemical insecticides are not the panacea they were once thought to be. First, the target insects have a remarkable ability to develop pesticide-resistance; second, chemical agents are not species specific and thus kill many other (often beneficial) insects in addition to the ones they were aimed at. Hence the increasing interest in the use of natural insect pathogens—parasites, bacteria, and viruses.

Of all the known insect pathogens, viruses appear to have the greatest potential for controlling insect pests. One group of viruses in particular—the Baculoviruses—seems to be especially suited to this purpose since natural epizootics of these viruses provide ample evidence of their lethality for the larvae of their host species. However, attempts to use Baculoviruses to control insect populations have yielded mixed results. For example, the corn earworm (*Heliothis zea*) has been effectively controlled by viruses in the USA, but attempts to control the East African armyworm (*Spodoptera exempta*) have not been as successful. Those equivocal results were largely a consequence of the crude and haphazard methods that were employed. In some instances infected larvae were simply mixed with water, mashed up and used as a spray. Little research was done on the nature of the viruses, the dose required, or the possible side effects of the viruses on the environment.

The effective use of biological methods of control depends on a substantial knowledge of both the pathogen and the host. The Natural Environment Research Council's Unit of Invertebrate Virology (UIV) was established in Oxford under the direction of Dr T. W. Tinsley in order to obtain more knowledge about insect viruses. Tinsley is collaborating with Dr P. Haskell at the Centre for Overseas Pest Research (COPR) on a research programme to study Baculoviruses and conduct field trials to determine the efficacy of these viruses as insecticides. The aim is to establish the conditions under which the virological control of insect populations would be effective, reliable and safe, and thus provide an alternative to the existing methods of controlling insects with chemicals. Tinsley and Haskell's work reflects a widespread revival of interest in the concept of 'integrated control'.

Integrated control is the manipulation of the insect's ecosystem so as to reduce the population of a pest insect species with minimal disruption of the environment. The technique relies heavily on biological pathogens that are specific for the pest species, but does not preclude the limited use of other agents including certain non-persistent chemical pesticides. However, before viral pathogens can be used in such a programme, they must be fully characterised. To quote Dr Tinsley, "the indiscriminate release of replicating viruses into the environment is as reprehensible as the indiscriminate release of chemicals".

The UIV/COPR programme is divided into the following four stages:

- The development of methods for identifying, purifying and isolating viruses pathogenic to insects.
- Investigation of the possibility that a useful virus could infect species of insect other than the target species, or even vertebrates, particularly mammals.
- Laboratory testing of the efficacy of the purified viruses as insecticides.
- Field trials to confirm the results of laboratory testing and to determine the dose that must be applied to obtain high rates of kill.

According to Dr D. Knudson of the Yale School of Public Epidemiology, the UIV programme is unique in that virological research, research into the potential environmental effects of insect viruses, and field trials to determine the best way of using the viruses as insecticides are combined into a unified programme. The research at UIV is concerned primarily, but not solely, with Baculoviruses isolated from *Neodiprion sertifer* (the pine sawfly) and from four species of the genus *Spodoptera*, namely *S. exempta* (the East African armyworm), *S. littoralis* (the Mediterranean cotton worm), *S. frugiperda* (the US fall armyworm) and *S. exigua* (the US beet armyworm), which are major pests in the areas in which they occur.

●Left: Dying larvae of Spodoptera littoralis hanging from lucerne stems. Centre: Pheromone trap used during field trials to keep a check on the moth population and, thereby, the extent of virus infection. Right: Derrick McKinley of COPR inspects the trap.

Before any Baculovirus can be released into the environment, its ability to infect other species of insect and vertebrates, such as birds (which feed off the insects), as well as the ecological problems that may arise from the collapse of an insect population must be studied. Fully half the research effort at UIV over the last five years has been devoted to ensuring that Baculovirus insecticides are safe and will not harm the environment. To date no evidence of any potential harmful effects has been found. However, as a result of the research that has been done by the UIV, and others, quite a bit is now known about Baculoviruses, their host range, the way they infect their host and the effect they are likely to have on the environment.

It is known, for example, that Baculoviruses contain DNA and are large, rod shaped particles (about 100 mm by 300 nm). Experimental studies have shown that the majority of Baculoviruses are species-specific, although a few types have a slightly wider host range. However, all Baculoviruses are restricted to invertebrates and, as a group, they appear to have no chemical, physical or biological properties in common with any other class of virus.

The ability of the Baculoviruses to infect mammalian cells is being tested at Porton, the British laboratory that was originally established to do research into defence against 'germ warfare'. The results so far indicate that Baculoviruses do not infect mammalian cells and do not cause disease in animals. However, the details of the viral replication cycle are not yet fully understood and there is a possibility that Baculoviruses could induce the expression of a latent virus, for example an oncornavirus, in a mammalian species. That seems to be a remote possibility, in view of the restricted host range of Baculoviruses, and in view of the large number of experiments in which no covert Baculovirus infections in tissue culture grown mammalian cells could be detected, but it is now being investigated.

Immunological techniques for identifying and distinguishing among Baculoviruses from different insects have recently been developed by the UIV. This is an important development, since it enables the viruses to be monitored after they have been released into the environment. Thus, if the population of a species of insect, other than the target species, collapses after the release of a Baculovirus it can be quickly determined if the virus that was released is responsible or not. The goal of any insect control programme is, of course, to reduce severely or cause the collapse of an insect population. The environmental effects of inducing such a collapse with a Baculovirus insecticide can only be estimated by examining the effects of natural epizootics of these viruses.

Two spectacular examples of Baculovirus epizootics have occurred—one in Canada during the late 1930s and one in Wales in the mid-1970s. In both cases there appeared to be no measureable effects, on, for example, the birds that normally fed on the target insects—they simply changed their diet. It is thought, therefore, that the environmental perturbations caused by species specific virus insecticides will be limited.

A substantial proportion of the research effort at UIV is concerned with the way in which Baculoviruses are disseminated under natural conditions, how they infect their host and how the natural infections are controlled. A characteristic feature of Baculoviruses that has been found to be important in their dissemination, and which also reduces their ability to infect vertebrates, is that they form polyhedral inclusion bodies which contain virus particles and which are highly resistant to disruption. The outer crystalline protein matrix of the inclusion bodies can only be disrupted at a very high pH (above 10) such as that which exists in the digestive tract of larvae. Insects appear to become infected with Baculoviruses by ingesting the virus and/or virus inclusion bodies with their food. However, the inclusion bodies cannot be disrupted by the human digestive tract (thus protecting humans from exposure to infectious virus) or by the digestive tract of birds. Inclusion bodies thus pass through the gut of birds that have fed on infected larvae and are disseminated in the environment.

The stability of the inclusion body has important implications for the way in which Baculovirus insecticides could be used. Since the infectivity of the virus inside the tough outer matrix is preserved it could mean that the virus could be readily stored as a dry powder or aqueous solution which need only be applied infrequently. On the other hand, it may be necessary to create an artificial epizootic every year. The only way to resolve this type of problem is to conduct extensive field trials.

Both the UIV and COPR have started field trials with Baculovirus insecticides. In Britain, the UIV has received clearance from the Ministry of Agriculture's Pesticide Safety Precaution Scheme to test the virus isolated from the pine sawfly (*N. sertifer*) to see if it can be used to control this forest pest. In the COPR programme, preliminary trials using the *S. littoralis* virus have been done in Crete and a more extensive study of this virus will be started soon in the Egyptian Fayoum. The preliminary results of these trials are very encouraging. For example, it has been found that spraying viruses from a low flying helicopter is an effective method of controlling *N. sertifer* — probably because the downdraught from the helicopter helps to distribute the virus.

In both the UIV and COPR trials novel ways of applying the viruses are being tested and, in keeping with the philosophy of integrated control, different combinations of agents are, or will be, used. An example of this is the proposed use of pheromones in Egypt by the COPR team. Pheromones will be used to attract male adult cotton worm moths (*S. littoralis*) into traps containing the virus insecticide. It is hoped that these moths will transmit the virus to the females during copulation who, in turn, will contaminate the outer shell of their eggs with the virus during oviposition. Since the first thing the larvae do after hatching is to eat their own eggshells, they will immediately become infected and die before they can do much damage to the crop.

The same rationale lies behind the concept of prophylactic spraying, enunciated by Dr Tinsley at the UIV. In this approach, low doses of viruses are sprayed before the eggs hatch. The advantages of this approach are first, that the larvae are killed soon after hatching and before they damage the plants or crops they normally feed on, and second, that since only low doses are needed to kill the hatching larvae, any possibility of upsetting the environment is minimised. The methods being tested in the field trials show clearly that the knowledge that has been obtained of the biology of the Baculoviruses and their insect hosts, is being put to good use.

Virus insecticides have the potential of being able to control many different species of insect. For the first time, therefore, we can envisage an alternative to the widespread use of chemical insecticides—and this at a time when chemical insecticides are becoming more and more expensive to manufacture.

In contrast, virus insecticides should be relatively cheap to produce, and should be within the capability of countries that do not have large petrochemical industries. Since a large proportion of the agricultural crops grown in the Third World are destroyed by insect pests, this research is potentially of enormous benefit to underdeveloped countries. ☐

US has doubts on anti-proliferation proposals

PROPOSALS presented jointly by the UK Atomic Energy Authority (UKAEA) and the US Electric Power Institute (EPRI) for reducing the proliferation dangers associated with nuclear power plans have received a less-than-enthusiastic reception from a number of groups concerned with US nuclear policy.

The proposals were announced at a meeting in Washington last February by Dr Walter Marshall, deputy chairman of the UKAEA, and Dr Chauncey Starr, president of EPRI. They involve a new system for reprocessing spent reactor fuel known as CIVEX which, it is claimed, makes the diversion of nuclear fuel virtually impossible by ensuring that pure plutonium is not accessible at any point of the cycle.

The proposed system is now being looked at closely as part of the International Nuclear Fuel Cycle Evaluation (INFCE) study, set up last year largely at the suggestion of President Carter. It has already been studied by a number of organisations in Washington, and received a variety of responses.

In the report of a study group set up to assess the CIVEX concept, the industry-based Atomic Industry Forum said that it found the concept to be "technically feasible" and "worthy of further development" and that it represents a considerable advance in answering fears that plutonium could be diverted from the fast-breeder cycle.

However the study group points out that there are a number of technical and economic questions that must be resolved before CIVEX's true potential can be realised. And it adds: "A breeder cycle embodying the CIVEX concept does not significantly increase diversion risk in comparison with no breeders at all. Other routes for obtaining fissile material exist independent of the breeder and dominate the diversion risk in either case".

Considerably stronger criticism of the CIVEX concept was made by one of the five members of the Nuclear Regulatory Commission (NRC), Mr Victor Gilinsky, speaking at a recent conference in London sponsored jointly by the AIF and the British Nuclear Forum.

"It is difficult to take CIVEX seriously as an answer to the manifest danger of dispersing plutonium in weapons usable form, a problem we will face, according to Judge Parker, ten years from now; there is no conceivable way this scheme can be implemented within the period Judge Parker has allowed us," he said.

Drawing on internal studies that have been conducted by NRC staff, Mr Gilinski, who was previously director of applied science and technology with the Rand Corporation, said that CIVEX fuel remained radioactive long enough to be self-protective for a "fleeting period of time" compared to spent fuel. Its radioactivity was so diminished a few years after leaving the reactor that it could not provide the protection for which it was designed, he said.

"Since most spent fuel reprocessed in this century will have cooled for longer than that, the CIVEX process cannot contribute to the solution of the problems we must worry about now," Dr Giliknsky said. The "abortive flurry" over CIVEX, underlined the importance of attacking the problem of plutonium return now.

Equally harsh words have come from public interest groups. An evaluation carried out by Jim Cubie of New Directions and Tom Cochran of the National Resources Defense Council comes to the conclusion that CIVEX is "much less promising than at first glance", and that rather than being proliferation proof, it at best increases proliferation *resistance*.

"Even though it is intended for use in the next mid-century, because CIVEX has been claimed to make reprocessing acceptable, it will be used as an excuse for undertaking new plutonium reprocessing ventures in the next few decades and thus spread nuclear weapons capabilities," the two authors say.

David Dickson

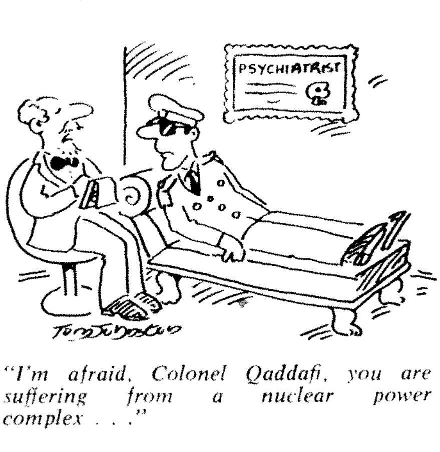
Libya bidding to join nuclear club, scientists warn

LIBYA is actively seeking nuclear weapons even though it signed the nuclear non-proliferation treaty three years ago, warns the Federation of American Scientists. The FAS is urging the Soviet Union to cancel an agreement to sell Libya a 400-megawatt nuclear power complex.

Jeremy Stone, director of the Washington-based federation, said that Ahmed al-Shahati, who is head of the foreign liaison office of the People's General Congress, told him openly that Libya is still trying to obtain an atomic bomb. "Shahati made no bones about it, saying they would seek all weapons with which to defend themselves," Mr Stone said of his conversation in Tripoli in October. "To be sure I understood, I asked again: were they seeking to maintain the right to get a bomb or actually trying to get the bomb itself? It was the latter."

The Soviet Union, whose policy is only to sell nuclear technology to countries that have ratified the non-proliferation treaty, announced the Libyan contract in October. The Russians are currently negotiating safeguards with the International Atomic Energy Agency to prevent nuclear fuel being diverted from the Libyan reactor to make weapons. Professor George Rathjens of the Massachusetts Institute of Technology, who is chairman of the FAS, estimated that the Libyan plant would produce enough fissionable material to produce "a couple of dozen" bombs a year.

In a letter to Anatoliy Dobrynin, the Soviet ambassador in Washington, Mr Stone asked: "Can the Soviet government rely upon the Libyan government to comply with the terms of the future IAEA safeguards agreement if Libya cannot be relied upon to comply with the treaty itself?"



"I'm afraid, Colonel Qaddafi, you are suffering from a nuclear power complex . . ."

Libya's nuclear ambitions were well known in the early 1970s, when its leader Muammar al-Qaddafi reportedly tried to buy nuclear weapons from China and later said he wanted to purchase the bomb from anyone who would sell it to him. Mr Stone said these attitudes did not change when Libya cynically ratified the treaty to become eligible for the Soviet reactor.

The FAS has also written to President Carter, asking him to take the matter up with the Russians and raising the possibility of international sanctions against Libya. There is not much the US can do on its own, Mr Stone said, apart from sending home the 2,000 Libyan students in American colleges and universities (10% of whom are studying nuclear science.)

The federation also named four other "potential false adherents" to the non-proliferation treaty: Taiwan, South Korea, Iraq and Iran. But Mr Stone did not claim to have any direct evidence that any of them was blatantly seeking nuclear weapons like Libya. □

0028–0836/78/0276—0550$01.00

Czech chartists claim two died in nuclear accident

CHARTER-77, the Czechoslovak human rights movement, last week entered the nuclear debate, with an exposé of conditions at the Jaslovske Bohunice power station. According to Document 22 of the Charter movement (distributed abroad by the Palach press), employees at the power station have been compelled (under threat of loss of premium payments) to expose themselves to radiation levels considerably above the safety standards, while, in the course of the last three years, two serious accidents, one of them causing the death of two workers, have taken place at the station. Indeed, claim the Chartists, since the second accident in February, 1977, the station is still "temporarily" closed.

The Jaslovske Bohunice power station has a long and chequered history. It was constructed under the terms of the Soviet-Czechoslovak general agreement for nuclear energy cooperation of April 1955. In 1956, it was predicted that the station would be commissioned in "about 1962"—in fact, it went critical in 1972 and became fully operational the following year.

According to Dr Frantisek Janouch, who at that time was working at the Czechoslovak Institute of Nuclear Research, and who took part in the many professional and organisational discussions relating to the construction of the reactor, the project was essentially a Soviet proposal and was carried out under Soviet supervision. The station uses a 110 MW gas-cooled heavy-water reactor. According to Dr Janouch, the Russians wanted to see if it was possible to construct an effective reactor of this type—leaving the details to be worked out by the Czechs and done at Czech cost.

In 1969, before the Jaslovske Bohunice station, known as the A-1, was completed, the Czechoslovak nuclear energy industry was switched, following a Soviet "recommendation", to light-water pressure reactors of the VVER type, for which the Soviet Union would supply "a substantial part of the main equipment". Whether this change of plan affected the final stages of work on the A-1 is not clear; it appears, however, from the Chartists' report that the projected automatic system for mounting new fuel elements was never brought into operation, and the mounting was done manually. Workers on the reactor were, says the report, "under psychological stress", often working a 16-hour shift instead of the six hours or less customary in "developed" countries. On 5 January, 1976, an error occurred in the mounting process. The element shot out of the reactor, under a pressure of 60 atmospheres together with a large quantity of radioactive CO_2. Since the emergency gas-traps and filters were insufficient for an accident of this magnitude, radioactive gas escaped into the atmosphere. In the area of the accident, emergency evacuation plans went into operation; unfortunately, one escape door had been locked, apparently to reduce petty thefts, and two workers were suffocated.

Some six weeks later, however, disaster struck again (according to the Chartists). During the mounting of new fuel cells, the primary circuit overheated, the air-tight seal of the steam generator ruptured, and, as a result, the primary circuit, part of the secondary circuit and the working area all became contaminated. Radioactive material entered the drainage system of the plant and a stream in the vicinity has since had to be "fenced off" as contaminated

During the repair work to the reactor, says the Chartists' document, safety levels of radiation were increasingly ignored, in an attempt to expedite the work.

The anonymous authors of the document urge nothing less than an open discussion and local referenda as to whether nuclear power stations should be constructed at all. This is all the more remarkable since uranium is Czechoslovakia's sole native energy source of any magnitude, and current plans evisage a nuclear expansion of 10,280 MW over the next 15 years, so that by 1990 over 30% of the installed generating capacity will be nuclear.

With such a major commitment to nuclear energy, the reaction of the Czechoslovak authorities to the report is predictably to deny everything. No such accidents occurred, they say, and even if they had occurred, they were under no obligation to make any public announcement.

Vera Rich

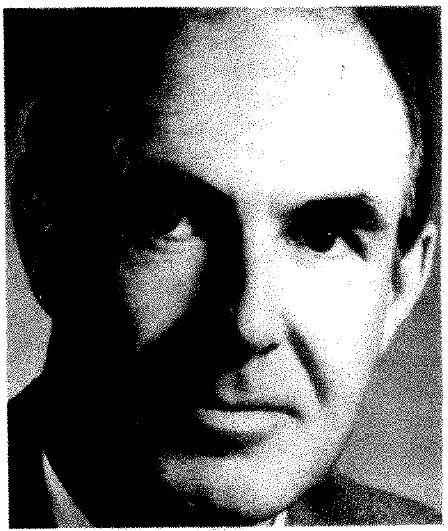
Canadian scientists confused by government moves on R & D funding

LAST week the Canadian Government appointed a new Minister of State for Science and Technology, Mr Alastair Gillespie. A brief occupant of the post when it was first established in 1971, Mr Gillespie will take over from Mr Judd Buchanan, who was promoted in a Cabinet shuffle to president of the Treasury Board.

One of the new Minister's first tasks will be to sort out the confusion created in the minds of many Canadian scientists by recent moves over the funding of research. In particular, a strategy announced earlier this year by Mr Buchanan pledging greater support for research and development has been followed by budget cuts severely reducing various areas of federally-funded research, particularly in government laboratories.

R&D policy has recently become a hot political issue in Canada, figuring prominently in the pre-election campaigns of all the main political parties. This prominence is based largely on the feeling that many of the country's economic problems have been due to its relatively low expenditure on research compared to other industrialised nations.

In June of this year, Mr Buchanan announced a number of funding increases and other measures designed ultimately, he claimed, to raise the proportion of the gross national product spent on R&D from 0.9% to 1.5% by 1983 (the comparable figure for countries such as West Germany and the US is about 2.5%).



Alastair W. Gillespie

In line with this strategy, a pre-election budget presented to the Canadian Parliament last month by Prime Minister Pierre Trudeau included a number of tax incentives to encourage private companies to invest in R&D. In particular, firms taxable at the small business rate will receive a new investment tax credit of 25% on all R&D expenditure; for other firms, the basic rate of the R&D investment tax credit will be doubled from 5 to 10%.

The Government's declared commitment to increase R&D support have

0028–0836/78/0276—0551$01.00

been welcomed by Canada's Science Council, which has recently been arguing that such moves are necessary to promote the country's technological autonomy. "We are delighted with the new tax incentives, particularly those for small businesses, which tend to be an important source of industrial innovation, and where Canadian ownership is concentrated", the council's executive director, Mr John Shepherd, said last week.

Members of the scientific community, however, while welcoming the Government's commitment, are concerned that too much emphasis may be placed on relatively short-term research objectives, with a corresponding neglect of more long-range, basic research. And widespread concern was expressed in September when it was announced that a number of areas of federally-sponsored research would be cut back as part of a package of austerity measures.

The effect of the cuts, which included closing down a number of internationally recognised government research stations, has been to reduce the 1979/1980 research budgets of the Department of Agriculture by $3.5 million, of Energy by $11.7 million, and of Fisheries by $11.1 million.

Budget increase of $5 million for the Natural Sciences and Engineering Research Council and $3 million for the Medical Research Council, announced by Mr Buchanan in June will remain relatively intact, with only $500,000 being taken away from each. However a $2 million reduction in the budget of the National Health Research and Development programme will mean the termination of several health care research programmes.

The Canadian Association of University Teachers and other university-based organisations have sent a telegram to Mr Trudeau warning him of the "disastrous" implications of the cuts for higher education, research and health care.

Public expressions of concern have not been without their effect. Last month the Government reversed its decision to close one of the oldest research stations in Canada, that attached to an experimental forest at Petawawa, Ontario; following considerable outcry, it has been agreed to keep the research station open, and to amalgamate into it two research groups currently based in Ottawa, namely the Forest Fire Research Institute and the Forestry Management Research Institute.

Nor has a number of universities been slow to realise that the future survival of their research efforts may depend on the extent to which they can build up a working relationship with both government and industry. This week, a two-day conference bringing together leading representatives of the three constituencies to work out mechanisms for co-operation is being held in Saskatoon, an event which some observers feel would have gained little support 10 years ago.

The scientific community must do more than simply complain about reductions in budget expenditures, says Dr John Kucharcyzk of the CFBS, which has organised the conference. "Instead we must continue to stress the importance of a vigorous scientific effort to reach Canada's overall economic objectives."

David Dickson

NASA plans a new Venus mission

As US scientists prepare to analyse the data from the four probes that began their descent through the atmosphere of Venus this week, the National Aeronautics and Space Administration is already working on plans for a follow-up mission to the planet.

The current Pioneer Venus mission is primarily concerned with sending back data on the atmosphere of Venus. In contrast the new mission, which NASA hopes President Carter will include in his budget request to Congress for the fiscal year 1980, would gather detailed information about the planet's surface and its internal structure.

The proposed Venus mission is at present top of NASA's priority list for new projects in the planetary sciences. Close behind is a project, scheduled for possible inclusion in the 1981 budget, to send a spacecraft past Halley's Comet as it approaches the sun in 1985 and on to an encounter with the Comet Tempel 2.

Both missions are expected to cost between $300 and $500 million, and are within the framework of the US Administration's policy for space science announced two months ago. In a "normal" year, NASA officials feel the new Venus mission would stand a high chance of being financed; but with the country in a cost-cutting mood, it remains to be seen whether NASA's request survives the budget process.

The new mission is known as the Venus Orbiting Imaging Radar (VOIR), and would involve a spacecraft circling the planet for at least seven months, providing the first detailed global view of its surface.

In the current mission, Pioneer Venus 1 will orbit the planet, and send back radar pictures. Their resolution, however, will not be much better than that which can already be obtained from Earth. The Soviet Venera missions have already sent back pictures transmitted from the surface of the planet, but only from three fixed locations.

The new spacecraft would, if it receives approval, be launched in December 1984 to arrive at the planet in May 1985. Radar mapping of the surface will be carried out using the synthetic aperture radar (SAR) successfully tested on the ill-fated Seasat mission; this will provide near-global coverage of the planet in moderate resolution, and coverage of a pre-selected small percentage of the planet's surface in high resolution (down to about 50 metres).

In addition to the SAR, the VOIR orbiter will also carry an altimeter and a magnetometer. It is hoped that the spacecraft will disclose the presence or absence of continents, ocean basins, volcanoes and other geophysical phenomena, as well as the nature and time sequence of any plate tectonic activity.

The proposed mission to the Comet Temool 2, which circles the sun once every five years, follows the abandonment last year of more ambitious plans for a close-range study of Halleys Comet, a mission for which NASA reluctantly decided it would have been too expensive to develop an appropriate propulsion system.

Part of the problem is that Halley's Comet circles the sun in an opposite direction from the earth, and a close encounter would have involved elaborate manoeuvring. The new plan is for a spacecraft propelled by the ionisation of mercury vapour to be launched on a course that passes close to the comet, dropping a probe into its tail, and then continues to a position that would allow it to travel alongside Comet Tempel 2 three years later.

Other projects submitted by NASA to the White House for possible inclusion in the 1980 budget include a gamma-ray observatory designed to study, for example, the high energy nuclear and gravitational processes which occur in the vicinity of neutron stars and black holes; an an advanced X-ray atrophysics facility which will provide high resolution data on the position and structure of celestial objects such as pulsars, binary-star systems, and quasars.

news in brief

● **Birmingham University to be prosecuted:** The UK Health and Safety Executive is to prosecute Birmingham University following the smallpox outbreak from the medical school last August which led to the death of Mrs Janet Parker, a medical photographer, and was followed by the suicide of Professor Henry Bedson, who was head of the laboratory. A date for the start of the hearing has yet to be fixed; a spokesman for the HSE believed it would be early next year.

The university is to be prosecuted for "alleged failure to ensure, so far as was reasonably practicable, the health of its employees in the east wing of the medical school," according to a statement by the HSE last Thursday.

In a statement, the HSE reaffirmed the need for all medical establishments to make sure that the necessary precautions were observed in dealing with all category A pathogens, especially smallpox. The safety guidelines are contained in the HSE publication "Control of laboratory use of pathogens dangerous to humans".

The HSE is to base its case on its own investigations. Meanwhile, Professor Reginald Shooter, chairman of the Dangerous Pathogens Advisory Group, is conducting an official government inquiry into the incident, which is also expected to be completed early next year.

● **US asked to reveal data on A-bomb tests:** The US Government has been asked to declassify all documents on atmospheric tests in the 1950s in an attempt to determine whether the tests were responsible for an abnormally high incidence of cancers in populations exposed to radioactive fall-out. The request has come from Governor Scott Matheson of Utah, who has expressed concern at an 11-year-old unpublished study by health officials which shows unexplained clusters of leukaemia victims in southern Utah in the path of fall-out from atomic bomb tests that took place between 1951 and 1962.

Thirty-eight claims have been filed against the Department of Energy by attorneys for survivors of cancer victims in southern Utah and Northern Arizona seeking more than $1 million in damages for each of nine cancer deaths. It is expected that up to 250 further such claims will be filed in the near future. The claims are the first to have been filed against the government on behalf of civilians not directly connected with the bomb testing programme, but merely living in the path of radioactive clouds.

Last week a federal judge in Newark, New Jersey ruled that the US Army must surrender films and recordings of atomic bomb tests conducted in 1953 in order that a 47-year-old cancer victim, who says he was forced to witness a blast, can compile evidence in a $13 million negligence suit.

● **£350,000 science awards:** Victor Hasselblad (right), inventor of the famous Hasselblad camera, who died earlier this year, left part of his fortune to establish awards similar to the Nobel prizes. From March next year, prizes worth a total of £350,000 are to be awarded each year to selected scientists for research into the natural sciences. The awards will be chosen by the Erna and Victor Hasselblad Foundation. According to a government official in Stockholm, Victor Hasselblad's instructions for the selection of scientists and the areas of the natural sciences for which the awards will be given, are in a sealed envelope which has yet to be opened by the executors of his will.

● **Lerner still cannot leave Russia:** Dr Aleksandr Lerner (left), the Moscow cyberneticist, has taken over the unenviable position as doyen of the *refusnik* scientists, now that Veniamin Levich has finally arrived in Vienna. Lerner, who is 66, has been waiting for an emigration visa for Israel for seven years. In the meantime, he has been working privately on a project for an artificial heart.

According to his daughter Sonia Levin, who visited London last week, Dr Lerner has now completed the basic control programme and the main priority is now for him to be able to collaborate freely with haematologists to establish the reaction of the blood to such an artificial organ. This, however, is not possible in the limbo conditions of a *refusnik* and the Soviet authorities have intimated to Dr Lerner that they would rather see him inactive in Moscow than doing useful work elsewhere.

Furthermore, some kind of personal reprisal seems involved due to Dr Lerner's activity in the Jewish emigration movement. US Congressman Rhodes, leader of the Republican party in the House of Representatives, says he was informed by the Soviet ambassador to the USA, that Dr Lerner would never be granted an emigration visa, because he is a "trouble maker".

● **Lead absorption higher than expected:** Scientists at the Atomic Energy Research Establishment at Harwell have shown that the proportion of lead from car exhausts absorbed by the human body is higher than previously expected. Denis Howell, Minister of State for the Environment, said: "This is an important finding and may be particularly significant where people are exposed to high levels of airborne lead from petrol."

The scientists confirmed that the majority of lead in blood comes from eating and drinking; lead from the air generally contributes less than 10% of the body's total uptake. However, at high concentrations, for example, people living near the busiest stretch of the M4, the contribution of air lead is comparable to that from diet. Sixty per cent of the lead inhaled by volunteers sitting near a motorway was deposited in the lungs. This finding agreed with earlier estimates. But the percentage of lead deposited in the lungs for people near urban roads was much higher than expected, at 48%.

The effect of lead on health, which was not considered by the scientists at Harwell, is to be assessed by a working party of independent experts which has been set up by the Social Service Secretary.

● **Kennedy plans hearings on biomedical research:** Senator Edward Kennedy has announced that the Senate health and science subcommittee of which he is chairman will hold a series of oversight hearings into the funding of biomedical and behavioural research early in the next session of Congress. Speaking during a ceremony to present the Albert Lasker awards for public health service and basic medical care research, Mr Kennedy said that in 1977 the US invested only 3.4% of its "health care dollar" in biomedical and behavioural research, compared with 4.9% in 1967.

"That decline in our overall commitment to research is short sighted and regrettable. It cheats our health care system of potential breakthroughs which will ultimately permit us to restrain health care costs without harsh regulatory controls. It has become apparent that our government has no clear system for setting priorities."

Risk assessment is more than numbers, Swedish seminar concludes

By Wendy Barnaby

"NEAR Santa Barbara, California, plans have been made to construct a large liquid natural gas terminal . . . A small group of American Indians is protesting the siting of the plant, contending that the chosen location is the most sacred spot of their culture, the Western Gate, where the Indians say the souls of their people must pass after they die to join the spirits of their ancestors . . . One can envision a Rasmussen-like report, examining the probability that a soul would be unable to migrate past a liquid gas terminal. The report would, no doubt, conclude that the risk was very small, perhaps 10^{-8} for each soul. To technical experts the risk seems negligible; to the Indians the risk is unthinkable . . ."*

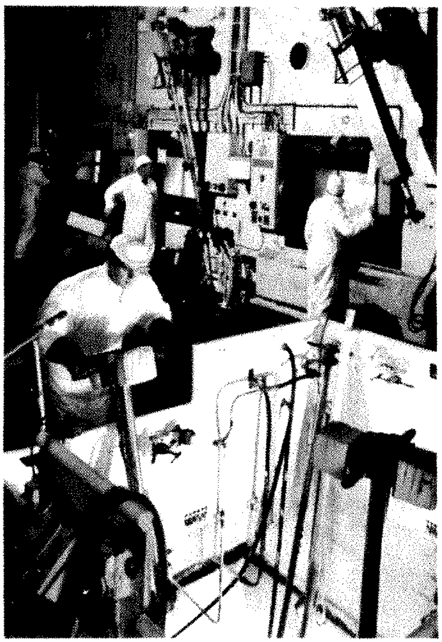
How can risk impact assessment (RIA) deal with value judgements? This emerged as one of the main themes of a three-day long seminar entitled "Impacts and Risks of Energy Strategies: Their Analysis and Role in Management", held recently in Stockholm. The answer, simply stated, is that nobody knows.

Scientists evaluate the risks involved in a proposed course of action; policy-makers draw up policies after they have weighed the risks in a social context; organisations carry out the policies—so the theory goes. The trouble is that this cycle involves scientific, social, psychological, political and managerial processes and disputes, and it is very hard to say how—or even by whom—they can all be brought together in some coherent whole.

According to Dr Baruch Fischhoff from Decision Research in Oregon, USA, RIA is limited by not having some inputs necessary for the analysis, by the analysts' inability to assess the validity of their work and incorporate that assessment into guidelines for action, and for its failure to address critical management issues. Some of the missing inputs are the preferences and values of the people who will be affected by whatever action is proposed: there is no adequate way of incorporating them into the numerical calculations that RIA demands. David Pearce, Professor of Political Economy from the University of Aberdeen, examined the issues that arose in the Windscale inquiry into whether or not to build an oxide fuel reprocessing plant in Cumbria, England, to see what—if anything—RIA could contribute. It is, he concluded, a valuable tool for ordering thoughts, but in considering issues like constraining the liberty of the individual or risking nuclear weapons proliferation and war, it has little or no role to play. RIA is, he inferred, unable to deal with ethical and political choices.

The problem of who should evaluate what in the RIA cycle was nicely illustrated by a difference of opinion between Dr Timothy O'Riordan from the University of East Anglia, and Mr Carl Tham, now Sweden's Minister for Energy. Arguing that the technically-sophisticated identification and estimation phases of RIA have been more fully developed than the evaluative and control phases, Dr O'Riordan said, "Ideally, the basis upon which key decisions are made in the evaluative and control aspects . . . should be made fully public and should be subject both to extra-parliamentary and parliamentary debate." Taking the academic's view, he saw this as a means of incorporating values into the cycle, to counter our present blind faith in scientific advice. Mr Tham, on the other hand, recommended quite a different procedure. "Politicians or decision-makers are best served with hardware facts about risks and their impacts on health and environment", he said. "Then it's our (ie the politicians') job to evaluate these facts as sensibly as possible and to make the necessary appreciation of costs and benefits." But can the politicians assume that they understand how the public perceives issues? There is "an immense gap between the views of technical experts and the views of a significant portion of the public", concluded Drs Paul Slovic, Sarah Lichtenstein and Baruch Fischhoff of Decision Research after studying opponents of a nuclear reactor to see how they perceived the threats it posed. Are the politicians informed and impartial enough to make their policies reflect these perceptions?

The RIA cycle does not end with the policy-makers, either: management, generally in the form of organisations, then takes over. But there is no guarantee that what is actually done will be even vaguely like what the policy-makers intended to have done: a gap demonstrated by Dr Shelagh Staynes fom London University's Monitoring and Assessment Research Centre, who talked about the administration of lead pollution ocntrol in the UK.



Reprocessing at Windscale: the risk may be high or low, but how to deal with ethical and political choices?

A more surprising difficulty with RIA is that there is so little communication between the different groups involved in it. The seminar—held jointly by the International Institute for Energy and Human Ecology (the Beijer Institute) and the Swedish Energy Research and Development Commission in association with UNEP—did at least get these groups talking to each other. Pointing out that natural scientists, politicians, psychologists and ecologists all contributed to the meeting, Professor Gordon Goodman, the Institute's Director, said, "There have been few occassions—it happens almost never—when people quantifying objective risk have talked to people trying to measure a democratic society's evaluation of risk perception. The policy-maker relates to the scientist and sometimes to the sociologist, but there has been no logical attempt to bring it all together." As far as Professor Goodman was concerned, however, the seminar summarised the state of RIA art and pointed to areas where more work could usefully be done to try to shed some light on the way many social policies are made. One of these, which the Institute hopes to take up, concerns threats of small probability but high significance: how could these be incorporated into RIA? How can the management process deal with them? Another area is "safety engineering": using RIA to identify technological systems' weak spots and cost-effective methods of improving them. Then there is a need for *post hoc* and comparative risk studies. The list is long, and illustrates how little we know about working out the greatest good for the greatest number. ☐

**From a paper presented at the seminar by Dr Raphael Kasper of the USA's National Academy of Science's Environmental Studies Board.*

Rothschild: an antidote to panic

SIR,—There are a number of inaccuracies or misrepresentations, doubtless unintentional, in the leading article (30.11 78) on my Dimbleby Lecture. I shall give a few examples.

- "Lord Rothschild . . . argued that we should develop a table of risks so that we could compare, say, the risk of our dying in an automobile accident with the risk of Baader-Meinhoff guerillas taking over (sic) the nuclear reactor next door." I specifically said that the risk of such a terrorist gang gaining entry to a nuclear power station was secret and *therefore unknown*
- The leader claims I implied that viewers could not convert "probabilities from one form to another". The reverse is the case as evidenced by the visual example given, actually on a pocket calculator which was seen by the audience. The example was 109÷109=1; 1,000.000—109=9,200. (Must I say, in *Nature*, that 1,000,000÷109=9,174.3119?)
- I was said not to have quoted "a single error on the risks I enumerated". The reason was quite simple the BBC did not like references to confidence limits or intervals, although I spent some time in the lecture on the importance of what I call "tolerances". In addition, I said that "1 in 100 is not exactly 1 in 100 in the world of risks, but, for example, *probably* somewhere between 1 in 95 and 1 in 105" If you had bothered to look at the printed version of the Dimbleby Lecture which was obtainable on 24 November, the day after the lecture was broadcast, you would have found references to confidence limits under six of the seven tables in the lecture. Ranges were given in the other one, Table 6 There are other misrepresentations which I did not expect in an editorial in *Nature*

What is more important is that your leader-writer has failed to understand the *constraints* imposed by talking about a highly complex and technical subject to 5 million people, the overwhelming majority of whom are laymen, in controdistinction to the few thousand who read *Nature*, and the *restraints* imposed by the BBC with their undoubted expertise.

I fear I am not competent to give a lecture on "the democracy of risk assessment", whatever you mean by that phrase. Let us hope your leader writer will soon give it, if only so that we know what it is.

As stated in the last but one paragraph of the lecture (p. 19), two of its main objects were to induce people to think about risks "for a minute or two", and "to compare the different risks around us." If I may quote myself in conclusion (p. 3) "Comparisons, far from being odious, are the best antidote to panic" In the editor's case the panic appears to be about the use of numbers.

ROTHSCHILD

N M Rothschild & Sons Ltd,
New Court, St Swithin's Lane, EC4

SIR,—In your forceful editorial, you assert that the quantitative assessment of risks is not enough and that emotional reactions also deserve a role in decision-making True, and indeed we live in a society where emotion is hardly likely to be under-represented in political decision-making. But emotional reactions are not necessarily and automatically decisive, and surely Lord Rothschild was merely concerned to get across the fact that such a thing as risk calculation exists and that *it* deserves a part in decision-making too Many non-scientists don't know how risks are calculated, especially on an a priori basis; is it arrogant to draw attention to the fact that such calculations *can* be made?

One of the most intractable problems in the discussion of nuclear power (and genetic experiments, et hoc genus omne) is that the expert is the victim of a classic catch-22: he can only acquire expertise of certain kinds, it is implied, by working in the industry or science that is under attack, and that, it is asserted, automatically destroys his objectivity (and the non-objective cannot be a real expert). But if emotional bias is to be automatically presumed in the expert, then how is the undoubted emotional bias of the external attackers (ex hypothesi, they cannot be experts!) to be assessed? Does not that bias nullify the validity of the attack? In this connection it should be remembered that a recent public survey in Britain elicited the fact that a large majority of the public prefers to trust the technical judgment of the experts on nuclear power, intellectual prostitutes though they apparently are

Emotional reaction to such things as nuclear reactors is a slippery basis for decision-making. I don't much like paying taxes, but I would hesitate to put that consideration too far ahead of dull calculations about the need to pay old age pensions somehow. How is allowance to be made for the fact that fears can be whipped up for reasons which quite often are largely political? Is it to be accepted that certain forms of risk are psychologically intolerable however small they are, for inscrutable reasons, whereas others are cheerfully accepted even though not negligible? For instance, it is notable that there are no public attacks on the transport of liquefied natural gas. Rothschild quoted figures implying that this process is even safer than nuclear power, yet a large LNG carrier bears explosive power equivalent to an atomic bomb. Though the LNG disaster involving a lorry in Spain indicates the destructive power of the fuel, the fact that no ship has blown up yet should not (on the analogy of the arguments applied to nuclear power) assuage the fears of those who live in harbour-towns where such ships are unloaded. Why not? Could it be that such an attack would be politically embarrassing beceause most LNG comes from the Third World?

Even if, for argument's sake, one postulates that no one working in the nuclear energy industry is to be trusted to give an honest opinion on contentious matters, it remains true that there exists a distinct group of experts, such as nuclear inspectors and medical radiation specialists, who can cast a cool and independent eye over some of the issues in dispute For instance, Sir Edward Pochin, who is a medical professor, recently gave a lecture entitled "Why be Quantitative about Radiation Risk Estimates?" (National Council on Radiation Protection and Measurements, Washington, D.C , Lauriston Taylor Lecture No. 2, 1978). He makes a number of points in the special field of medical radiation protection which are very reminiscent of Lord Rothschild's and in the last part of his lecture he puts together some risk calculations from the UN, OECD, the International Commission on Radiological Protection, the US National Safety Council and the like (all, one would think, immaculately independent bodies) and concludes that the death risk from the total radiation exposure, from the entire uranium cycle, for an average citizen (including 'nuclear workers' in the average), in a country where one kilowatt electrical power per citizen comes from nuclear stations, is equivalent to the death risk from smoking one cigarette every two years. He adds that he recognises that relative acceptabilities of the two risks is another matter, but believes that "the numerical comparisons of this type do have a certain value in letting radiation be seen in a proper context as one of the numerous potentially harmful components of the occupational, as of the general, environment. . " The essential answer to your objection to Lord Rothschild's lecture, surely, is that it can only be beneficial to have context.

Two other brief points should be made about your editorial. Firstly, you point out the special difficulty of assessing 'unknown risks'—risks of something that has never yet happened, like a serious reactor accident, or a major LNG ship disaster But surely it is a very odd attitude to treat, by implication, something so safe that it has never yet gone seriously wrong over a period of years, as more suspect (merely because no *historical* risk estimate is feasible) than, say, coal-mining or deep-sea fishing? This implies that the more successful an industry is in minimising fatalities (and the nuclear power industry has, to date, a unique record), the larger the part that emotion (as distinct from facts) should play in assessing its desirability. Odd!

Finally: you make the intrinsically very powerful point that one cannot quantify the risk of the loss of some civil liberties if nuclear power expands, or, for that matter, quantify the emotional reaction to that eventuality. But who shall assess the risk of major social disorder occasioned by very serious energy shortages in future if nuclear power is stopped, and what numerical value would such a disamenity carry?

That kind of argument always pulls in two directions.

Emotion is unavoidable in this kind of debate, and your readers will no doubt discern a smidgin of it in this letter. But in science, emotion should be the engine and reason should hold the steering-wheel and press the accelerator and brake. Risk analysis quite properly helps to guide the foot between those rival pedals.

Robert Cahn

The University of Sussex,
School of Engineering and
Applied Science.

We did not wish to imply that emotional commitment characterised only one side of the nuclear debate—far from it—only that it was impossible to assess risks without taking such factors seriously. Further, the unknown risk referred to was the risk of failure of a commercial scale fast breeder reactor, for which there is no experience.—Ed.

Solar activity and influenza

Sir,—I would like to elaborate further on the remarkable correlation between influenza A viral antigenic shifts and peaks of the sunspot cycle as noted by R. E. Hope-Simpson (*Nature* **275**, 86; 1978).

Ancient "cosmic and telluric theories" regarding influenza epidemics date as far back as the time of Hippocrates (Thomson, D. & Thomson, R. *Ann. Pickett-Thomson Res. Lab.* **9**, 257–261; 1933 and **10**, 1125–1140; 1934). Over half a century ago, F. G. Crookshank (*Mil. Surg.* **59**, 284–290; 1926) defended the hypothesis that influenza pandemics and solar activity were correlated, and this possible relationship was further studied by M. Mygge (*Acta Med. Scand.* suppl. XXXII, 105–134; 1930). Since the discovery of a filtrable virus as the aetiological agent of influenza in the 1930s, the notion of a solar-influenza association has been largely dismissed and forgotten.

Except for the pandemic of 1889, the beginning dates of historical influenza pandemics in the 18th and 19th centuries (Mote, J. R. In: *Viral and Rickettsial Diseases*, Harvard University Press, 257–261, 1933), as well as pandemics and viral antigenic shifts in this century (Kilbourne, E. D. *J. Amer. Med. Assoc.* **237**, 1225–1228; 1977), appear to have occurred in years of high sunspot number. From our present knowledge of influenza, it is not unreasonable to assume that these severe historical pandemics spreading rapidly to world-wide proportions were associated with major shifts in the influenza A haemagglutinin (H) and neuraminidase (N) surface antigens.

The mechanisms on how the solar cycle can affect influenza pandemics may only be speculated upon at this time. The amount of ultraviolet light incident on the surface of the earth is increased in years of high sunspot activity (Pettit, P. *Astrophys. J.* **75**, 185–221; 1932), and this can conceivably accelerate the mutation rate of the influenza virus. The relationship between long-term cyclical fluctuations in meteorological and climatic conditions with the sunspot cycle remains controversial at this time. It is plausible, nevertheless, that during years of high solar activity, a more favourable ecological environment may exist for the genetic recombination of human and animal influenza viruses, with the emergence of new pandemic strains.

It is interesting to note that while the swine influenza virus (HswlNl) reappeared in 1976, its spread into pandemic or even epidemic proportions did not occur in this year of sunspot minimum. The resurfacing of the HlNl subtype ("Russian flu") in December of 1977 was completely unexpected. The sunspot cycle was beginning its rapid ascent at that time.

It would not at all be surprising if a new strain of influenza A virus should emerge and dominate in the sunspot maximum years of the near future. On the other hand, perhaps what could only be expected from the elusive influenza virus is the unexpected.

Seveso: premature optimism

Sir,—At the recent Seventh International Congress of Pharmacology in Paris, Dr G. Reggiani of the Hoffman-La Roche Medical Board presented a communication on the clinical features of the July 1976 TCDD accident in Seveso. The Mario Negri Institute have closely followed many aspects of the investigations since then, and we feel some comment is necessary.

TCDD (2,3,7,8 tetrachlorodibenzo-p-dioxine) is one of the most powerful known toxic chemicals in animals, especially as regards its cumulative and delayed effects. So there cannot but be serious concern about the long term effects of the accident on man, regardless of the present impossibility of making any defensible prognosis (S. Garattini *Biomedicine* **26**, 28–29; 1977).

Since the accident, Hoffman-La Roche, which owns ICMESA through its subsidiary Givoudan, has been faced with many problems, of which public relations is certainly not the least. Its representatives have with every right denied false or exaggerated press reports such as charges that ICMESA had been secretly engaged in manufacturing warfare chemicals. After a while, though, they began to comment optimistically on the potential health risks to people living in the polluted area. For example, Dr Reggiani noted that: "In the case of TCDD man seems to respond to a certain extent differently from other animal species . . . " (J. Walsh *Science* **197**, 1064–1067; 1977). There is no question that all efforts to minimise exposure of the residents in the disaster area should not be discontinued and we fervently hope Dr Reggiani's opinion proves right. But he seems to be rushing it somewhat by extending his increasingly sanguine attitude to retrospective evaluation.

His Paris communication was obviously biased by his desire to make little of the possible damage to human health. Thus he offered reassuring interpretations of findings such as those on chloracne, the typical skin lesion after TCDD exposure in humans, pointing out its "quick healing tendency" with the unsupported implication that it was quantitatively linked to exposure. He failed to mention its recurrence in people from widely scattered areas. Regardless of whether they were based on poorly reliable data such as observed rates of spontaneous abortion, Dr Reggiani confidently presented negative findings as strong evidence for the absence of TCDD induced pathology, with no criticism of the epidemiological methodology adopted or related problems deriving from the lack of adequate historical controls.

These points are evident from his abstract in the official volume (*Abstract n.* 2890, 953) which concludes: "The measures of protection of the population and prevention of further damage carried out at our request by the local authorities have avoided the severe injuries observed in previous similar accidents".

In view of this statement we must recall that the Seveso case cannot be compared with any previous accident involving TCDD because of 1) the uprecedently heavy contamination of inhabited areas, 2) the delay in recognising the nature of the accident and the resulting lag before protective measures were adopted, and 3) the significant amounts of TCDD persisting in the environment where people live. No mention of the TCDD risk was made to the local authorities before the disaster and even after it. Roche took almost two weeks to admit that TCDD had escaped from the plant.

It is unfortunate when someone takes advantage of a scientific meeting to present such misleading statements. People with no knowledge of the background and complexity of the Seveso case and the difficulty of epidemiological studies, may be led to accept the idea that thanks to Roche, all is well in Seveso now. This sounds outrageous to those who have already suffered distress from the disaster, apart from all considerations of feared future effects on health, which only time will reveal.

In addition and perhaps most relevant, our concern about Dr Reggiani's statement is of practical value. Everybody knows how difficult it is to motivate people to keep coming back for the controls needed for epidemiological studies. If the idea is spread around that there are no risks it will be difficult to collect long term data. No data available may well represent the best possible proof that no toxic effects occurred!

"Mario Negri", Milan, Italy

Reflections on the occasion of my birthday, by Mr Davy

It has been a matter of some gratification to me, in my present rather distant circumstances, to note that the Anniversary of my birth has not gone unnoticed by your esteemed Journal. I refer, Sir, to the remarkably accurate and well executed likeness of the lamp which is associated with my name, that occupies the entirety of your frontispiece. By the yardstick of eternity two hundred years is a mere nothing It would be churlish to complain of a lack of recognition, were it not that various dabblers and meddlers have received more than their proportionate share of such credit as your transitory World offers. It is true that the Royal Institution has seen fit to mark this Anniversary with an exhibition. But why is access restricted to Tuesdays and Thursdays between the paltry hours of noon and four? And why do they charge a derisory fleabite of only twenty pence? In 1811, in Dublin, tickets cost two whole guineas to hear me lecture on 'Peculiar Observations in Electrochemistry' And even so all five hundred and fifty tickets were sold within a week. Subsequently I was told the self-same tickets changed hands on the street at up to twenty guineas apiece! In those days Chemistry was much more popular as a subject for lectures, than Astronomy, Mechanics, or Natural History. A critic wrote, 'These subjects are not susceptible of any brilliant exhibitions, there is no noise, no fire—and the amphitheatre never fills, but for Mr Davy. A small bit of Potassium thrown in a glass of water, or upon a piece of ice, never fails to excite a gentle murmur of applause! And the audience consisted of young Gentlemen together with an equivalent number of young Ladies of High Quality.'

I know that Dalton and Faraday have done very well since—they have Divisions named after them in the Chemical Society. But as for Dalton all that talk about atoms; it was mere speculation, no experimental evidence As I said at the time, 'it's more ingenious than important'. And as for Mr M. Faraday, I very much resent those who say that he was my greatest discovery. Let me remind you that, whatever became of him afterwards, he was only my Assistant. He may have discovered the Laws, but I discovered the Elements: Sodium, Potassium, Calcium, Magnesium, Barium, Strontium and Chlorine Electricity from my Giant Pile was able to exert a power on substances such as had not been exerted before. Even mighty Soda and Potash yielded themselves to sustained attack. Not all Savants could accept my simple view of the little molten globules emerging through the crust of the potash and bursting into purple flame. This was not to be the last time that Gay-Lussac and his henchman Thenard obstructed the course of Natural Philosophy. Carried away by their isolation of Boron—a remarkable achievement for them—I may have perchance referred to Gay-Lussac as being the Head of Living Chemists in *France*. But their notion that *my* Potassium was a mere Hydride of Potash could not be sustained and can only be regarded as being vexatious. No wonder I resent Gay-Lussac's Bicentennial—200 francs a head, no half price for children and open all the week including Sundays! I grant you that M. Lussac was a competent experimentalist; somehow his numbers always fitted. But Laws are merely reflections of Man's puny attempts to describe the omnipotence of the Supreme Being:

> "All things most glorious on the Earth
> Tho' transient and short lived they seem,
> Have yet a source of heavenly birth
> Immortal,—not a fleeting dream"

And I speak of Experiments, not Laws As I once said, 'It is more laborious to accumulate facts than to reason concerning them; but one good experiment is of more value than the ingenuity of a brain like Newton's.'.

My first experiments were conducted in Mr Tonkin's house in Penzance and relied on such apparatus as wine-glasses, tea-cups, tobacco-pipes and crucibles, securing preference upon the kitchen stove to the more ordinary domestic comestibles. I shall always be beholden to the generosity of Dr Thomas Beddoes and the Pneumatic Institute of Bristol but it was at the Royal Institution, following the work of Nicholson and Carlisle, that I demonstrated that Hydrogen and Oxygen alone were the true products of galvanic action on pure water. I discovered to my manifest astonishment that the two gases could be separated if two gold plates, dipped into separate vessels of water were linked by the fingers of my own hands This was not the first time that my body had been used as a tool in the Laboratory And, a fig, Sir, for your Health and Safety at Work Act! In 1806 I demonstrated the relation of electricity to chemistry using three vessels connected by moist fibres In front of the very eyes of an audience, I immersed metal plates in two outer vessels containing Barium Nitrate and Sodium Sulphate and these outer vessels were linked each to the other through a third vessel containing pure water. The action of the Giant Pile on this apparatus brought forth a magnificent deposition of solid white Barium Sulphate in the middle vessel. Such a spectacle could only be interpreted as a manifestation of Nature's innermost Secrets. For the first time I realised that some substances were attracted and some repelled by the quality of the electrification of the plates. I declared 'These attractive and repulsive forces are sufficiently energetic to destroy or suspend the usual operation of Chemical Affinity'. One cannot speculate with profit on the nature of electricity, but I had no doubt it was connected with Chemical Affinity and the very essence of Matter.

The Lamp you have, Sir, in your frontispiece, should not be the only reminder to your Readers of the festive Season. Why, Sir, on Boxing Day—aptly named—in 1799 I discovered the medical properties of Nitrous Oxide. I enclosed myself in an airtight breathing box, having a cubic capacity of about nine and a half cubic feet. I was in the box for one and a quarter hours, and breathed over twenty quarts of pure nitrous oxide. A thrilling extending from the chest to the extremities was almost immediately produced. I felt a sense of tangible extension, highly pleasurable in every limb; my visible impressions were dazzling and apparently magnified. By degrees as the pleasurable sensations increased, I lost all connection with external things; trains of vivid visible images rapidly passed through my mind and were connected with words in such a manner, as to produce perceptions perfectly novel. I existed in a World of newly connected and newly modified ideas I theorised; I imagined that I made discoveries. And that is why, Sir, I crave the courtesy of your columns to enquire why I should be remembered only by my Lamp (as if I was Miss Nightingale) rather than as the Father of British Anaesthesia. I need hardly remind you that the Poet Southey wrote 'Davy has invented a new pleasure for which language has no name. I am going for more this evening, it makes me strong and happy! So gloriously happy! Oh, excellent air-bag!' And in 1801 Wordsworth and Coleridge beseeched me to teach them Chemistry in a special Laboratory to be constructed at Keswick. Had I acceded to their request and gone to the Lake District, rather than the Royal Institution, the benefits to English Literature and to Chemistry remain to this day, Sir, incalculable

Intervening sequences in the mitochondrial genome

from Giorgio Bernardi

SINCE its foundation by Boris Ephrussi 30 years ago, mitochondrial genetics has made great advances and yet this subject has remained an area of interest to only a small number of laboratories. Whatever the explanation for this, the situation is not likely to last much longer since exciting results recently obtained in one particular system, the mitochondrial genome of yeast, should stimulate very wide interest.

The mitochondrial genome of *Saccharomyces cerevisiae* comprises about 100 identical, circular, supercoiled DNA molecules per diploid cell. Each genome unit is about 50 million in molecular weight, a value five times greater than that of the mitochondrial genome of organisms as far apart in terms of evolution as *Chlamydomonas* and man, but smaller (by a factor of almost two) than that of higher plants. Each genome unit is known to encode two ribosomal RNAs, at least 30 tRNAs, and nine proteins: three of the seven subunits of cytochrome *c* oxidase, one of the seven subunits of the *bc1* complex, three of the ten subunits of the ATPase complex, and one protein, *var1*, of unknown function. The other mitochondrial proteins are specified by nuclear genes, a fact which emphasises the very close cooperation between nuclear and mitochondrial genes in mitochondrial biogenesis and function.

The fivefold difference in unit size between the mitochondrial genomes of yeast and, say, man, is difficult to explain in terms of coding potential since it is unlikely that the former codes for so many more gene products than the latter. Put in a different way, the discrepancy between the unit size of the mitochondrial genome of yeast, about 50 million, and the amount of DNA required to encode its known gene products, about 10 million, raises the same problem as the so-called 'c-value paradox' of the nuclear genome of eukaryotes, namely, what is the role of the 'excess DNA'? An answer to this problem is emerging from two different experimental approaches

A direct molecular approach revealed, some years ago, that half of the mitochondrial genome of yeast consists of AT spacers (GC<5%) formed by short, repeated dAT : dAT and dA : dT sequences. The other half, presumed to correspond to the structural genes and to their regulatory elements, is extremely heterogeneous in base composition (since it ranges from 21% GC for ribosomal genes, to about 35% GC for tRNA genes, to 65% GC for GC-rich segments representing 10% of the genome) and contains 60–70 clusters of the sequences CCGG and GGCC[1] which are palindromic and homologous in sequence[2,3], as originally postulated by Prunell and Bernardi. By cutting these clusters with the restriction enzyme *Hae*III, the genome can be split into 60–70 fragments, most of which seem to be formed by a GC-rich region, a gene (or gene segment, see below), and a spacer. Interestingly enough, the *Hae*III fragments vary in length and (to some extent) in number in different strains, two factors which are responsible for a variation of ±5 in the size of the corresponding genomes[4].

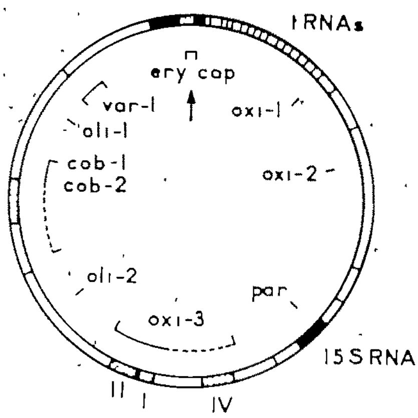

Fig. 1 The mitochondrial genome of *S. cerevisiae* modified from Borst & Grivell *Cell* (in the press). The location of the genes for 21S and 15S RNAs is indicated. Thin, radial lines indicate the position of tRNA genes. Roman numerals indicate genome segments absent in *S. carlsbergensis*. The 21S RNA insert is represented by the dotted region splitting the 21S RNA gene. The approximate location of a number of genetic markers as well as the *cob* loci referred to in the text is indicated inside the ring. The arrow indicates the origin of the map which corresponds to a *Sal*I site.

The functions of the spacers, of the (CCGG, GGCC) clusters and of the GC-rich segments are still a matter of conjecture. The presence in them of homologous or quasi-homologous sequences appears, however, to be responsible for the high frequency of recombination phenomena which characterise the mitochondrial genome of yeast. Unequal crossing-over events seem to account for the changes in length of *Hae*III fragments, which accompany genome evolution[4] and genome recombination in sexual crosses[5] as well as for the excision of genome segments leading to the defective genomes found in spontaneous 'petite' mutants[6].

Giorgio Bernardi is Head of the Laboratoire de Génétique Moléculaire, Institut de Recherche en Biologie Moléculaire, Paris, and Co-Director of the Institute.

0028-0836/78/0276-0558$01.00

The starting point for the genetic approach was the discovery of the so-called mit$^-$ mutants in which mitochondrial functions are impaired by point mutations or small deletions affecting the mitochondrial genes coding for the subunits of respiratory enzymes or of ATPase. Mapping work in several laboratories has revealed that both the *cob* (or *box*) region, coding for apocytochrome *b* (the mitochondrial subunit of the *bc1* complex), and the *oxi-3* locus (which codes for subunit I of cytochrome *c* oxidase) correspond to DNA segments several times larger than expected (see Fig. 1). More recent work[8] indicates that non-coding regions and regulatory sequences are present within the *cob* region. The data of Slonimski *et al.*, for instance, indicate that mutants lacking functional cytochrome *b* map in seven discrete clusters dispersed over 6,000–10,000 base pairs. Mutations at non-adjacent loci 4/5, 1 and 6 fall into a single complementation group and produce abnormal apocytochrome *b*. On the other hand, mutations at loci 2, 3 and 7 complement mutations at loci 4/5, 1 and 6, complement each other, and present a disturbed synthesis of both subunit I of cytochrome *c* oxidase and of cytochrome *b*. Most of these pleiotropic mutants are temperature-sensitive and accumulate multiple 'new' mitochondrial translation products. The genetic and biochemical work just mentioned is further supported by electron microscopic work[9] on hybrids between the 18S mRNA transcribed from the *cob* region and restriction fragments from the same region; this shows that the gene for cytochrome *b* consists of at least five coding regions separated by four non-coding regions which are between 600 and 2,000 base pairs long.

At least one other mitochondrial gene, the gene for the 21S RNA, is also split, in addition to the two already mentioned. Electron microscopy of 21S RNA with a restriction fragment containing this gene, show that this contains a 1000 base pair insertion which is closely correlated with the ω^+ allele, a polarity locus affecting the transmission of neighbouring genetic markers in crosses[10,11]. Strains having the ω^- allele lack the insertion, which is always transmitted in $\omega^+ \times \omega^-$ crosses to the ω^+ progeny. Very interestingly, a large intervening sequence[12] containing tRNA genes[13,14] has been found in the gene for the 24S RNA of *Neurospora* mitochondria.

An important question raised by these findings concerns the relationship of intervening sequences with the sequence elements (spacers and GC-rich segments) discussed above. More specifically, it may be wondered whether some of the homologous sequences present in those elements are not used in the RNA splicing. While current biochemical and genetic work will certainly lead to an answer to this question, it is noteworthy that the large regions of strain-dependent genome variability are correlated with the presence of long dA:dT sequences and map at the *cob* and *oxi-3* regions (Fig. 1). Finally, it should be noted that while the presence of split genes further weakens the hypothesis of the prokaryotic origin of mitochondria, its main interest undoubtedly resides in the fact that intervening sequences have now an easy genetic handle which should allow us to gain a better understanding of these puzzling genome elements. ☐

Enzyme defects and immune dysfunction

from Fred S. Rosen

GENETIC deficiency of two enzymes in the purine degradation pathway, adenosine deaminase (ADA) or nucleoside phosphorylase (NP), results in fatal immunodeficiency disease. E. Giblett (University of Washington, Seattle) discovered ADA deficiency serendipitously while examining erythrocytes for informative enzyme polymorphisms from a child with severe combined immunodeficiency (SCID), a profound deficiency of T and B lymphocytes. She subsequently discovered NP deficiency in a child with severe T cell deficiency. These are the only genetically determined immunodeficiencies that have a known biochemical basis. Although ADA and NP are distributed in all mammalian tissues, only the lymphoid system is affected by the deficiencies.

A meeting was held recently at the Ciba Foundation* to discuss the biochemical consequences of ADA and NP deficiency, particularly as to how they affect the ontogeny of lymphocytes.

Both ADA and NP deficiency are inherited as autosomal recessive phenomena. ADA has been assigned to chromosome 20 and NP to chromosome 14. ADA deficiency results in a more profound immunodeficiency than does NP deficiency. Of all infants affected with the autosomal recessive form of SCID, 35 to 50% have ADA deficiency. NP deficiency is known in only six kindred. Affected children in these six kindred have a severe A cell deficiency, normal immunoglobulins, increased antibody responses, autoantibodies, and poor *in vitro* responses to mitogenic stimuli (A. Ammann, University of California, San Francisco). By contrast, ADA deficiencies have a profound defect of both T and B cells and no *in vitro* or *in vivo* immunological function. Although the erythrocytes are completely deficient in ADA, a mutant enzyme has been found in fibroblasts and lymphocytes in low amounts (approximately 15% of normal). This has enabled the prenatal diagnosis of this disease in amnion fibroblasts (R. Hirschhorn, New York University, New York).

It was found that NP deficients accumulate 2′-deoxyguanosine triphosphate (dGTP) in erythrocytes, and lymphocytes whereas ADA deficients have abnormally high levels of 2′-deoxyadenosine triphosphate (dATP) in these cells (A. Cohen & D. W. Martin, University of California, San Francisco). D. A. Carson (Scripps, La Jolla) showed that preferential T cell trapping of deoxyadenosine and deoxyguanosine and subsequent accumulation of dATP and dGTP is due to the high kinase content of T cell lines and their relative poverty of 5′-nucleotidase. L. Thelander (Karolinska Institute, Stockholm) obtained calf thymus ribonucleotide reductase in high purity. The allosteric regulation of this enzyme requires 1×10^{-3} M ATP as a positive effector, and is readily inhibited by dATP and to a lesser extent by dGTP and dTTP. dCTP has no inhibitory effect. In fact, dCDP can rescue murine mutant S49 lymphoma cells that have ADA and/or NP deficiency. N. M. Kredich (Duke University, Durham) offered a very reasonable explanation for the greater severity of ADA deficiency in that adenosine accumulation inhibits the hydrolase of S-adenosylhomocysteine. This substrate accumulates and clogs the methyl donor activity from S-adenosylmethionine. Thus DNA synthesis in ADA$^-$ lymphocytes is obstructed at the ribonucleotide reductase step and DNA methylation is inadequate.

Establishment of lymphoid chimaerism with transplants of histoidentical marrow has been the most satisfactory therapy for ADA deficiency. Lacking a bone marrow donor for an ADA deficient infant, S. H. Polmar (Case Western Reserve, Cleveland) used frozen human erythrocyte transfusions as a source of exogenous ADA. This succeeded in reducing dATP levels in lymphocytes and inducing normal immune function. This procedure was extended with further success to an NP deficient child (B. J. M. Zegers, Wilhemina Kinderziekenhuis, Utrecht). W. N. Kelley (University of Michigan, Ann Arbor) has obtained both ADA

0028–0836/78/0276—0559$01.00

and tissue ADA binding factor in a high state of purity. Purified ADA awaits trials of its clinical usefulness. Also, on theoretical grounds, deoxycytidine may have therapeutic benefits for NP and ADA deficients.

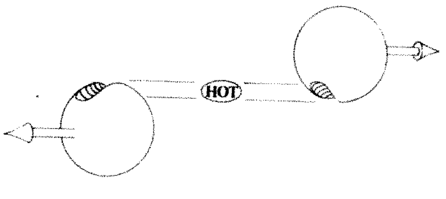
J. F. Smyth (Royal Marsden Hospital, Sutton, Surrey) has infused terminal cancer patients and patients with T cell acute lymphocytic leukaemia with deoxycoformycin, a potent ADA inhibitor. He achieved striking lymphocytocidal effects. Potent immunosuppressive and oncolytic agents may emerge from the study of these rare immunodeficiencies which result from a failure of purine breakdown. ☐

Multipion production in relativistic heavy-ion collisions

J. M. Irvine

IN recent years the nuclear physics community has been excited by the possibility of new accelerator systems capable of producing relativistic heavy-ion beams. There has been theoretical speculation for several years about using such beams for producing new, exotic nuclear phenomena such as superheavy elements, nuclear shock waves, pion condensates (the nuclear analogue of a ferromagnetic phase transition) and quark matter.

If one fires high energy nucleons at one another the most obvious products are pions, and one of the first things to be understood about relativistic heavy-ion collisions then is the pion production. Earlier this year (Fung *et al.* *Phys. Rev. Lett.* **40,** 292; 1978) data became available from the Bevalac at Berkeley on negative pion production in relativistic heavy-ion collisions from beams of ^{40}Ar at 0.4, 0.9 and 1.8 GeV/nucleon and ^{12}C beams at 0.4 and 2.1 GeV/nucleon on targets of LiH, NaF, BaI$_2$ and Pb$_3$O$_4$. As was to be expected theoretical papers aiming to interpret the data have followed thick and fast. The simplest picture (Vary, *Phys. Lett.* **40,** 295; 1978) considers that the colliding nuclei are moving so much faster than the internal velocities of the nucleons of which they are composed that this internal motion can be ignored and the heavy ion collision can be viewed simply as a large number of independent nucleon-nucleon collisions. Vary's calculations predict too many events with high negative pion multiplicities, that is, events where more than 15 negative pions are produced, and attempts to correct this feature by allowing the pions to interact with the nucleons to produce baryon resonances have not been successful. A better account of the pion multiplicities is provided by the fireball model (Gyulassy & Kauffman *Phys. Rev. Lett.* **40,** 298; 1978). In this model, as the target and projectile sweep by each other, the material in the geometrical overlap is swept out and assumed to be at rest in the centre of mass frame. The enormous initial kinetic energy is assumed to be converted into internal thermal energy. The pions are assumed to be produced in this extremely hot fireball fragment (see Fig. 1). Gyulassy and Kauffman conclude that this model is adequate to explain the pion multiplicity data and come to the conclusion that the independent nucleon-nucleon model predicts too many high multiplicity events because it ignores pion absorption. They go on to assert that there is a very large class of dynamical models which will give results identical to those of the fireball model: the only requirements on the models being that the pions are uncorrelated and that the average pion multiplicity is correctly given.



This assertion seems to be supported by recent results of Afek *et al.* (*Phys. Rev. Lett.* **41,** 849; 1978) using the collective tube model. This model uses a geometrical picture of the heavy ion collision like the fireball model and considers the collision of two 'tubes' of nucleons in the target and projectile nuclei. In the centre of mass frame the colliding tubes are Lorentz contracted into narrow disks and the model then assumes that the tube–tube collisions resemble elementary particle–particle collisions. The agreement between the predictions of this model and the data of Fung *et al.* is extremely impressive. Afek *et al.* go on to claim that the agreement between the predictions of the colliding tube model and statistical thermodynamic models, like the fireball model, is entirely accidental and will disappear at higher energies for heavy projectile-heavy target systems. ☐

J. M. Irvine is in the Department of Physics, University of Manchester.

Sinks and sources of plant nutrients

from Peter D. Moore

COMMUNITIES of emergent aquatic plants are known to be among the most productive found in temperate latitudes. Dykyjora (*Photosynthetica* **5,** 329; 1971) examined three such littoral plants, *Phragmites communis, Typha angustifolia* and *Scipus lacustris* and obtained values for their productivity (means for the whole growing season) of up to 25, 39 and 21 g m^{-2} day^{-1} respectively. In part these high values can be explained in terms of the structure and arrangement of leaves; leaf area index is high for all these species and all possess underground rhizomes which act as storage organs and which permit rapid leaf production at the commencement of the growing season. A further factor which contributes to the high productivity of swamp habitats is the normally adequate water supply and the frequently rich provision of nutrients in the water flow.

Tropical swamps also have very high productivity. For example, Thompson (in *The Nile, Biology of an Ancient River* (ed. Rzoska) Dr W. Junk, The Hague; 1976) has estimated that papyrus (*Cyperus papyrus*) swamps in East Africa achieve values of 35 g m^{-2} day^{-1}. As with their temperate counterparts, these plant communities also place high nutrient demands upon their environment and accumulate these nutrients within their living biomass and in the peat which develops from the undecomposed litter.

Gaudet (*Ecology* **58,** 415; 1977) has measured the nutrient uptake capacity of papyrus and has obtained the following values (g m^{-2} yr^{-1}) N, 103; P, 8; K, 130. These figures are similar to published data concerning *Typha latifolia* for P and K, but are twice as high for N. Such very high accumulation rates have subsequently led Gaudet to consider the value of such papyrus communities for the extraction of nutrients and hence the reduction of eutrophication in East African lakes. Nutrient cycles being what they are, however, much of the NPK build up in the biomass is released in litter decomposition. Gaudet has measured the rate of nutrient release, both through decomposition and through the direct leaching of living tissues and has estimated the proportion of the annual nutrient uptake which would enter swamp peat. The figures he obtained are N, 63%; P, 1% and K, 1%. Thus most of the P and K are released back into the environment,

---

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences, King's College, London.

0028–0836/78/0276—0560$01.00

but much of the nitrogen is taken out of circulation in the peat deposit. As a system for nutrient extraction from eutrophic waters, it might be more efficient to harvest the emergent biomass periodically, but not so frequently that it would result in the undue depletion of rhizome resources. Overcropping is known to weaken some temperate emergent plants; Conway (*J. Ecol.* **30,** 211; 1942) demonstrated such an effect in *Cladium mariscus*, which is reduced in its growth vigour if harvested more frequently than once every four years.

Just as the development of a peatland habitat acts as a sink for the major plant nutrients, so the destruction of a peatland often results in the flushing of such elements back into the environment. Such has been Israel's experience in the Hula Basin to the north of the Lake of Tiberias (Sea of Galilee). Here, extensive swamplands dominated by *Phragmites* have been drained in recent years and the peaty soils have produced rich agricultural land. As in the fens of eastern England, however, there has been a subsidence of the surface, ammounting to about 10 cm yr^{-1}, as a result of the drying and contraction of the peat and its gradual oxidation.

Avnimelech (2nd INTECOL Congress, Jerusalem, 1978) reported a further and more serious problem in the release of large quantities of nitrate from the wasting peat. It is estimated that 20,000 tons of nitrate nitrogen may be released from the area and up to 5,000 tons yr^{-1} have been carried by the Jordan into Lake Tiberias. Such eutrophication, it is feared, could influence the local fishing industry.

Attempts have been made to control floodwater from the Hula Basin, for the greatest movements of nitrate downstream are associated with floodwater. But the most successful measure adopted so far has been the encouragement of denitrification. Alternate wetting and drying of the peat stimulates microbial denitrification and the use of sprinkling has now reduced nitrate leaching into drainage waters by 50%. One of the main crops on the peatland is alfalfa, which is a surprising choice in view of its symbiotic nitrogen fixation. The use of a nitrogen demanding crop species such as rice would seem more appropriate from a nutrient cycling point of view, but is currently precluded by economic considerations. ☐

Faint images revealed

from F. G. Smith

The modern generation of optical astronomers now rely heavily on television and photon-counting techniques, so much so that photography seemed to be rapidly going out of date despite the introduction of sensitive fine grain films such as Kodak IIIa. Competition is, however, a powerful stimulus, and there are now some new photographic techniques giving astronomical photographs which cannot yet be equalled in sensitivity and detail by any new electronic device.

The first step was the hypersensitising of emulsions by soaking in dry nitrogen followed by hydrogen gas. This technique, which gives a large improvement in quantum efficiency, is routinely used in the southern sky survey at the UK Schmidt telescope in Australia. The second step is surprisingly simple, and involves only the method of taking contact copies from the new sensitised plates.

D. F. Malin of the Anglo-Australian Observatory, observed that the photographic grains in faint images are concentrated in the upper layers of the emulsion, while the background fog is distributed throughout the whole depth. He found that contact printing with a diffuse light could be arranged only to reproduce the upper layer, and thereby enhance the signal-to-noise ratio of faint images. He describes the techniques in a note on page 591 of this issue of *Nature* and shows some remarkable results on photographs of the extragalactic nebula Centaurus A and the supernova remnant in Puppis. Faint extensions of both objects are revealed for the first time.

These results are exciting for astronomy, and most gratifying as a further example of a widely useful technical advance stimulated by the needs of pure research.

F. G. Smith is Director of the Royal Greenwich Observatory, Herstmonceux.

More on X-ray bursts

from A. C. Fabian

Spring and autumn are the seasons of the rapid burster. This object produces up to several thousand X-ray bursts per day over intervals of 2-6 weeks in March/April and September/October. Its location near the Galactic Centre means that each burst, of but a few seconds duration, emits in X-rays as much energy as the Sun emits in all wavelengths in one day. Large X-ray detectors on the first High Energy Astronomical Observatory (HEAO-1) were pointed at the rapid burster on 31 March of this year, yielding the light curves shown on page 587 of this week's *Nature*. A collaboration of experimenters from Massachusetts Institute of Technology, University of California at San Diego and Goddard Space Flight Center have found evidence for spectral changes in the decay of rapid bursts.

A spectral softening is observed, but to a less marked extent than appears in other X-ray burst sources, where the burst interval may be many hours. The softening in these other sources may be interpreted as black-body cooling (see for example Swank *et al. Astrophys. J. Lett*, **212,** L73-L76; 1977), leading, with some assumptions as to the luminosities, to a measure of the size of the emitting region. This seems to be relatively constant and is consistent with the surface area of a neutron star (van Paradijs *Nature*, **274,** 650-653; 1978). The region responsible for the optical bursts seen coincident with bursts from MXB 1735-44 (Grindley *et al. Nature*, **274,** 567; 1978) is considerably larger.

There is at yet no detailed theoretical model of the rapid burster, although accretion instabilities in matter flowing onto a neutron star seem a likely candidate for the basis of any such model. The 6 month interval between periods when the burster is observed has also yet to be explained. SAS-3 observations to be published next January (Marshall *et al., Astrophys. J.* in the press) show that a trend in bursting behaviour occurs over the period for which the source is visible. This may imply that the 6 month timescale is intrinsic to the source and not, for example, due to obscuration by a binary companion.

Thermonuclear flashes near the surface of an accreting neutron star have been proposed as the source of the X-ray bursts that are observed to recur on intervals of hours. The flashes are due to a thermal runaway in the helium burning layer of accreted matter. Numerical computations of this process have recently been published by P. Joss (*Astrophys. J.* **225,** L123-L127; 1978) and demonstrate that X-ray bursts can be produced that bear a striking resemblance to the ones observed. The flashes occur at such a depth that heat is transported out fast enough by radiative diffusion that X-ray temperatures are achieved at the photo-

---

A. C. Fabian is Radcliffe Fellow in Astronomy at the Institute of Astronomy, Cambridge.

0028-0836/78/0276—0561$01.00

sphere. Joss' model did not produce flashes if the temperature of the core was too high, although the core was still in thermal equilibrium with the time-averaged heat flow. X-rays are, of course, produced more efficiently by gravitational energy release when the matter is first accreted. The ratio of accretion luminosity to thermonuclear luminosity L_a/L_n must be $\geqslant 30$, for conventional neutron star models, and ~ 300 for Joss' model. $L_a/L_n < 25$ for MXB1759-29 and is $\leqslant 2$ for the rapid burster, if it is assumed that the accretion luminosity emerges as relatively continuous X-rays over the same time interval as that on which bursts are observed. This tends to rule out thermonuclear flashes for the rapid bursts and may prove to be a problem for this model in general. Future work on X-ray bursts will one hopes improve our knowledge of neutron stars and thereby teach us some high energy physics. □

Gene conversion in mitochondria

from D. H. Williamson

THE article on page 577 of this issue by Strausberg and his colleagues from Dallas will rekindle interest in a long-standing problem in the mitochondrial field, namely the mechanism of recombination between mitochondrial DNA molecules.

Mitochondrial genetics is dominated by work on bakers' yeast, and has been ever since the discovery in this organism, some 15 years ago, of the first mitochondrial point mutations conferring resistance to either chloramphenicol or erythromycin. These drugs block protein synthesis on mitochondrial ribosomes, and it happened that these first resistant mutants all mapped close together in the region we now know specifies the 21S mitoribosomal RNA. These mutants were the first tools with which mitochondrial recombination in crosses could be studied, and quite early on, a puzzling phenomenon emerged; in certain crosses, a marked polarity was observed amongst the recombinants, alleles carried by one parent being greatly favoured at the expense of those represented by the other. This polarity was not observed in all crosses, and it was soon realised that any strain could formally be categorised as carrying a hypothetical determinant called omega (ω) in one or other of two configurations, ω^+ and ω^-. Polarity of recombination was observed only in $\omega^+ \times \omega^-$ crosses, and not in either of the other two pairwise combinations. The ω determinant was independent of the mating type of the cell, but an early idea was that its role was a sexual one analogous to Hfr in bacteria and, for a while, the notion of mitochondrial sex was in vogue. However, when mutants in other unlinked genes were discovered, making four-point crosses feasible, it became clear that the analogy with bacterial sex was invalid, and in 1974 the Gif group (Dujon, Slonimski & Weill *Genetics*, **78**, 415; 1974) proposed a comprehensive model to account for all the facts then known. Esentially their model supposes that the mitochondrial DNA molecules in pairs of mating cells undergo repeated rounds of recombination. At the level of the individual molecules, recombination events are considered always to be non-reciprocal. However at most loci, gene conversion can go randomly in either direction, thus generating equal numbers of reciprocal recombinant types in the population as a whole, and obscuring the non-reciprocal nature of the events at the molecular level. At the ω locus, on the other hand, the conversion is seen as always occurring in one direction, effectively favouring alleles of the ω^+ parent, and at the same time unmasking the asymmetric nature of the molecular interactions.

We have since learnt that as far as the events at the ω region are concerned, this model is broadly correct. It has recently been shown that the 21S RNA gene of ω^+ strains carries an insertion of about 1,000 base pairs which is absent from ω^- strains. It is this insertion that seems to be responsible for 'directing' the conversion events in its immediate vicinity. Until now, however, no comparable phenomenon had been discovered in other regions of the genome, and the events at ω were coming to be regarded as something of an odd-ball.

In the light of today's article from the Dallas group, this view becomes a shade less tenable. This group reports on a rather similar state of affairs affecting a recently discovered mitochondrial gene called *var*1. This gene owes its name to the fact that its polypeptide product varies in size in different strains, the extent of this variation amounting to some 4,000 daltons, or around 10% of the polypeptides' molecular weight. The work on *var*1 is of unusual technical interest, since its function is completely unknown, and all the genetic analyses have revolved round the ingenious application of gel electrophoresis to bulk mating populations. With the aid of a variety of genetic and physical mapping procedures, the Dallas group have already precisely located the *var*1 gene on the map, and have shown that the altered sizes of the variant forms of the polypeptide directly reflect changes in the size of the structural gene itself.

The current paper reports on the behaviour of different *var*1 alleles in crosses. It shows, rather clearly, that alterations in the size of the gene (and hence of its polypeptide product) arise as a result of asymmetric gene conversion events involving two small DNA segments (about 36 and 57 base pairs long) which can be independently inserted, by recombination, into alleles which lack them. The very demonstration of these events in a system in which phenotypic expression is restricted to the rate of migration of protein molecules in a gel, is something of a *tour de force*, and fully deserves our admiration. However, the observations have a wider significance in that the phenomena look rather similar to those seen at the ω region. In both cases the gene conversion events occur at high frequencies, and both regions possess insertions presumably responsible for 'directing' the non-reciprocal recombination events at the locus, thereby making them detectable in the overall molecular population.

The main conclusion is clear. Gene conversion is not restricted to the ω locus, and its occurrence at other regions of the genome may have been missed before now simply because of the lack of strategically placed pairs of markers to make it visible. Although no other protein products have been observed to behave like *var*1, there is no lack of evidence for other insertions in the genome (see the Strausberg article for references). Nor is there any lack of models embodying gene conversion to explain some unresolved problems in the transmission genetics of this system. Evidence such as that presented on page 577 begins to invest such models with an air of respectability. □

The first division

from Clive Lloyd

PROTOPLASTS prepared from tobacco leaves now form the staple experimental diet of investigators studying viral infection, somatic hybridisation, wall synthesis, properties of the plasma membrane—the list goes on—but the intriguing fact goes almost unnoticed that in the process of removing the cell wall, non-dividing leaf cells are stimulated to divide. For instance, remove palisade cells from tobacco

0028–0836/78/0276—0562$01.00

leaves and few will divide in culture, but remove the wall from such cells with degradative enzymes and about half of the protoplasts go on to divide Nagata & Takebe, *Planta* **92,** 301; 1970), (although it is a common observation that protoplasts must first resynthesise a cell wall before division takes place) It would seem from this that some assembly at the cell periphery is controlling cell division in such a way that its perturbation by enzymes unlocks the potential for growth. This will come as no surprise to animal cell biologists who will be reminded of the ability of some proteases to tweak density-inhibited fibroblasts into another round of division, but compared to animal cells, the role of the cell periphery in controlling cell division has been little studied in plants. A major barrier to studying the plant cell surface with techniques used for animal cells is the cell wall itself; it prevents easy access to the plasma membrane of probes such as proteases, lectins and antibodies, which have helped outline the regulatory role of the cell surface in the division of lymphocytes However, some recent papers hint at potential ways in which the problem can be tackled using protoplasts and a recently adopted wall-inhibitor

Schilde-Rentschler (*Planta* **135,** 177; 1977) reported her work on the role of cell wall formation in the ability of tobacco protoplasts to form callus, finding that the addition of a cellulase preparation to tobacco mesophyll protoplasts inhibits their division. Enzymes used to degrade cell walls are notoriously—and perhaps necessarily—crude preparations. so it is difficult to pin-point cellulose deposition as a prerequisite for division when so many other sites are probably affected simultaneously. However, by adding the disaccharide, cellobiose (believed here to be inhibiting cellulase activity), to protoplasts cultured in the presence of the enzyme mixture. Schilde-Rentschler was able to restore to protoplasts the capacity to divide, thereby claiming a direct involvement for cellulose formation in allowing division to take place. It is unclear from this whether cellulose biosynthesis triggers cell division or whether cellulosic wall formation simply provides the mechanical framework which allows the division of protoplasts stimulated to do so during the earlier event of wall removal. A series of papers from Meyer *et al.* favours the latter possibility, suggesting that wall formation, although required for organised cytoplasmic division, may be unnecessary in the events which lead to nuclear division.

To get protoplasts to divide at all in culture was, originally, far from straightforward and most workers use variations of media found successful for tobacco leaf protoplasts Unlike such media which osmotically cushion the fragile protoplasts with sugars, Meyer & Abel (*Planta* **123,** 33; 1975) used instead, salts for maintaining osmotic strength. In this alternative system, tobacco protoplasts regenerate only a pseudo-wall which differs from wall regenerated in sugar medium by being discontinuous (patches of wall-less membrane exist which permit cell fusion in the presence of polyethyleneglycol), non-rigid (does not resist plasmolysis) and lacking in some typical wall enzymes However, the regeneration of such a pseudo-wall still permits a form of cell division to continue for 2-3 rounds Cytoplasmic division can, therefore, take place in the absence of a rigid cell wall, but related papers (*Planta* **125,** 1; 1975; *Planta* **142,** 11; 1978) showed that the quality of those divisions is abnormal. In more normal circumstances, cells would divide by coalescence at the equator, of vesicles containing materials which go to form the separating wall; but with reduced competence to form wall in the salts medium, the empty vesicles fuse and perforate the daughter cells in a manner likened to the budding of yeasts.

Now, in their most recent paper, Herth and Meyer (*Planta* **142,** 253; 1978) go one step further and prevent even pseudo-wall formation by using a reversible inhibitor of cellulose formation 2,6-dichlorobenzonitrile. In this case, no cytoplasmic division is observed, but nuclear division continues In fact, Meyer and Herth report that within 6 days of culture, as many as 90% of the protoplasts have performed at least one mitosis, forming, two-, four-, and multi-nucleate cells The fact that nuclear division occurs in the presence of this inhibitor not only confirms that nuclear and cytoplasmic division are seperable, but that the sequence of events leading to nuclear division continues to operate in the absence of extensive deposition of cellulose The mitotic activity of wall-less protoplasts has been reported previously by several authors, but the potential interest of the present system is that the wall-less state can be maintained by the presence of inhibitor, thereby allowing any possible role of the plasma membrane in regulating mitosis to be examined. Further quantitative data on the contribution that nuclear division, as opposed to cell fusion, makes to the polynuclear state, would be welcomed, as would a greater understanding of how the inhibitor works. Whether or not these particular experiments stand the test of time, their general motive seems right: that we should seek novel approaches to investigate the role of the cell surface in regulating plant cell growth ☐

Can magnetic order and superconductivity coexist?

from B. R. Coles

IT has long been recognised that in rough approximation magnetism and superconductivity are sworn enemies This is shown not only in the ability of an applied magnetic field to destroy the superconductive state but also in the strong suppression of T_c, the transition temperature, by additions of magnetic-moment bearing atoms, where simple solutes have little effect When enough magnetic atoms have been added to destroy superconductivity it is often succeeded at low temperatures by a state in which the solute moments couple by way of the (now normal) conduction electrons In random solid solutions the resultant state cannot easily be one of long-range magnetic order—it is now generally called a spin glass but there have recently been discovered some atomically well-ordered intermetallic compounds containing a fraction of moment-bearing atoms (rare earths with partly filled 4f electron shells) where tendencies towards magnetic order and towards superconductivity are both present. These are compounds of the form RE Mo_6S_8 (Fischer *et al Solid State Commun* **17,** 721; 1975)—the Chevrel phases—and of the form RE Rh_4B_4 (Matthias *et al. Proc natn Acad. Sci U S A.* **74,** 1334, 1336; 1977) where RE is a rare-earth metal In the latter group of compounds superconducting transitions were found for RE given by Y, Nd, Sm, Er, Tm or Lu, but it was later found that in the Er compound (Fertig *et al Phys Rev Lett.* **38,** 987; 1977) the superconductivity setting in at 8 7 K disappears with the formation of a state of magnetic long-range order below 0 9 K. The presence of magnetic order was inferred from a pronounced λ type specific heat anomaly and an accompanying susceptibility peak, neutron diffraction experiments have

since demonstrated (Monckton *et al* *Phys. Rev. Lett.* **39**, 1164; 1977) that the order is ferromagnetic.

It is impressive (and to some people surprising) that these properties of Er Rh_4B_4 can be given a convincing discussion (Jarlborg *et al. Phys Rev. Lett* **39**, 1032; 1977) in terms of a calculated electronic structure. That any reasonable form of band structure calculation for a compound containing three types of atom and eighteen atoms per crystal unit cell can now be carried out is a testimony to the enormous progress made in such calculations by the combination of intelligent choices of calculational schemes and large amounts of computing capacity The superconductivity seems to be associated with a high density of 4d-electron states (per unit energy) at the Rh atom sites, just as in the superconductivity of pure V and Nb (although for other reasons not in pure Rh), while the rather small density of states for 5d electron states on the Er sites, provides a magnetic coupling like that in pure Er between the local 4f moments on these sites This, while not as strong as that between the larger 4f moments which completely suppresses superconductivity in favour of magnetic ordering in Gd Rh_4B_4, does finally, below 0.9 K, enable magnetic order to appear.

It seems not unreasonable that a long range magnetic order of ferromagnetic character should be incompatible with superconductivity since there is no sharp separation between two types of conduction band electrons (4d-like on Rh and 5d-like on Er), and the long-wave-length (zero wave-vector) spontaneous parallel spin pairing which is the essence of ferromagnetism cannot coexist with the Fermi surface antiparallel pairing which is the essence of normal superconductivity. The other forms of pairing which parallel the superfluidity of liquid ^3He are, as yet, only gleams in the eyes of theoreticians

In other groups of compounds, the Chevrel phases RE Mo_6S_8 and RE Mo_6Se_8, there has, however, been some evidence for the coexistence of superconductivity and long range magnetic order Thus, the La Jolla group (see the review by Maple in *Transition Metals*, 655; 1977 (Inst Physics Conf Series No 39, 1977)) have found specific heat anomalies below T_c in RE Mo_6Se_8 for Sm, Gd, Tb, Dy and Er, which they ascribe to the formation of a state of magnetic long-range order, probably antiferromagnetic, within the superconducting phase field In view of the important theoretical implications of such a coexistence (in formal terms a divergence in the wave-vector dependent susceptibility χ (q) at some antiferromagnetic wave vector q_0 while χ (0) goes to zero) it is of great interest that it has proved possible very recently to show the antiferromagnetism of the Dy compound unambiguously by neutron diffraction techniques.

In a recent paper (Monckton *et al. Phys Rev. Lett.* **41**, 1133, 1978), research workers from the pioneer Geneva group, from Bell Labs and from Brookhaven have used the Brookhaven neutron scattering facilities to examine a specimen of Dy Mo_6S_8 down to a temperature of 50 mK, and have shown conclusively that this material (which becomes superconducting at 2.05 K) develops long-range antiferromagnetic order at 0 4 K. Conventional powder diffraction patterns taken above and below this temperature, together with high resolution scans of certain peaks, have permitted the identification of the detailed magnetic structure and yielded estimates of the ordered moments, which show some suppression by crystal field effects from the free Dy^{3+} ion values

The coexistence of superconductivity and antiferromagnetic long-range order is now proven; a theoretically satisfactory account of such coexistence has yet to be produced ☐

A star called M

from S. Jocelyn Bell Burnell

IN THE good old days (that is more than 10 years ago) people believed that neutron stars would only be detectable (if at all) through their steady, thermal optical emission Calculations of the expected brightness are difficult to perform realistically; heat is generated in bizarre circumstances by friction between charged particles and a neutron superfluid in the interior of the star and there is heat loss by radiation from the surface, but the character of this radiation is drastically modified by the presence of a magnetic field of about 10^{12} gauss Indications are that the surface temperature should be about 10^6 K and that the most readily detectable neutron stars would, optimistically, be within the grasp of the world's largest telescopes or, more realistically, might be just beyond them

In the event, however, neutron stars were detected much more readily by radio astronomers (as pulsars) and soon afterwards by X-ray astronomers who concluded that many of the strong X-ray sources in our Galaxy were powered by a neutron star's gravity Radio astronomers now know of some 300 pulsars. All pulse regularly, and their periods range from 33 ms to about 4 s. But only two of these three hundred have been detected at optical wavelengths. They are two of the most rapid pulsators—those in the Crab and Vela nebulas—and it was through their pulsed optical emission that the star responsible was ultimately identified in each case

The Vela pulsar proved difficult to detect at optical wavelengths At one stage astronomers despaired of detecting pulses and looked for a star whose emission might be accounted for as steady thermal radiation of a hot neutron star On these grounds Lasker suggested as candidate a star he called M That star called M turned out to be the pulsar

Now events have taken another interesting turn bringing us back, almost, to where we started The group that discovered the optical pulsations from Vela report (Peterson *et al Nature* **276**, 475, 1978) that some 50% of the optical emission from this star is unpulsed. A series of frames taken during the pulsation cycle of the star shows quite clearly the double-pulsed profile which is its signature, and some residual light during the 'off' part of the pulsar's duty cycle. However, there is too much steady emission for it to be thermal emission from the surface of the star and they are forced to consider other possibilities Perhaps it is the pulsar emission reflected off a cloud of gas or off the surface of the star; perhaps there are several sources of emission around the star which blur together; perhaps there are very broad pulses which fill the whole cycle

They find a similar but perhaps less dramatic effect for the Crab pulsar. Here again there were technical difficulties, but this time it was the detection of the weak, steady emission in the face of the short but bright flash from the pulsar Whereas the Vela pulsar needed 8 hours' observation with the 3.9 m Anglo-Australian Telescope, the Crab pulsar needed only 10 minutes' observation with the telescope stopped down to approximately half aperture! The conclusion is that the Crab too has steady optical emission, and although it's a smaller proportion of the total emission once again it is too copious to be accounted for by a thermal mechanism

It will be interesting to see whether the latest generation of EUV and soft X-ray astronomy satellites can observe a similar effect Meanwhile these incredible stars continue to puzzle, and occasionally to surprise Less surprising will be the inevitable spate of papers which endeavour to explain this latest result ☐

review article

A gene complex controlling segmentation in *Drosophila*

E. B. Lewis
Division of Biology, California Institute of Technology, Pasadena, California 91125

The bithorax gene complex in Drosophila *contains a minimum of eight genes that seem to code for substances controlling levels of thoracic and abdominal development. The state of repression of at least four of these genes is controlled by* cis-*regulatory elements and a separate locus (Polycomb) seems to code for a repressor of the complex. The wild-type and mutant segmentation patterns are consistent with an antero-posterior gradient in repressor concentration along the embryo and a proximo-distal gradient along the chromosome in the affinities for repressor of each gene's* cis-*regulatory element.*

THE segmentation pattern of the fly provides a model system for studying how genes control development. The phylogeny, although not the ontogeny, of that pattern is reasonably well understood. Flies almost certainly evolved from insects with four wings instead of two and insects are believed to have come from arthropod forms with many legs instead of six. During the evolution of the fly, two major groups of genes must have evolved: 'leg-suppressing' genes which removed legs from abdominal segments of millipede-like ancestors followed by 'haltere-promoting' genes which suppressed the second pair of wings of four-winged ancestors. If evolution indeed proceeded in this way, then mutations in the latter group of genes should produce four-winged flies and mutations in the former group, flies with extra legs. In *Drosophila*, not only have both types of mutation been observed, they have been shown to involve a single cluster of pseudoallelic genes known as the bithorax complex (BX-C)[1-7]. During evolution a tandem array of redundant genes presumably diversified by mutation to produce this complex[1,4]. During development the BX-C genes seem, on the basis of evidence to be summarised in this article, to control much of the diversification of the organism's thoracic and abdominal segments. It is as if during ontogeny the BX-C genes recapitulate their own phylogeny.

Each of the wild-type thoracic and abdominal segments has a unique pattern of differentiated structures (Fig. 1*a*) which constitutes a morphologically defined state or 'level of development' (L). Each BX-C mutant phenotype can be described in terms of the degree to which one or more segments, or portions thereof, are transformed from one such level to another. As shown in Fig. 1*b* a striking feature is that the metathoracic (MT) and first three abdominal segments (AB1, AB2 and AB3) can approach or achieve almost all segmental levels of development from a mesothoracic level (LMS), or 'primitive' level[1], to a third abdominal level (LAB3), depending upon the genotype. The wild-type allele of each BX-C gene (Fig. 2) will be assumed to code for a BX-C substance (S) which controls one or more components of an intersegmental transformation (Table 1). The various BX-C substances are presumed to act indirectly by repressing or activating other sets of genes which then directly determine the specific structures and functions that characterise a given segment. On such a model the level of development which a segment achieves depends upon the particular array of BX-C substances elaborated in that segment. When the wild-type and mutant phenotypes are interpreted in accordance with this model, it can be seen from Fig. 1*b* that the attainment of any level more

Table 1 Summary of the roles of BX-C substances (S) in controlling specific types of body segment transformations and specific structures in one or more segments of the larva

Gene	Substance	Segmental transformation	Larval structures affected	Genotypic comparisons (from Fig. 6)
bx$^+$	S_1*	LAMS → LAMT		
pbx$^+$	S_2	LPMS → LPMT		
Ubx$^+$	S_0*	LMS → LMT	DLT	*a* vs *b*
				f vs *h*
bxd$^+$	S_3	LMS → LAB1	DLT†, VP, KO, VSB	*g* vs *h*
lab-2$^+$	S_4	LMS → LAB2		*b* vs *c*
			DLT, KO, VSB	*c* vs *h*
lab-3$^+$	S_5	LAB2 or LMS → LAB3		*e* vs *f*
lab-5$^+$	S_7	LAB4 or LMS → LAB5		
lab-8$^+$	S_x	LAB7 or LMS → LAB8	DLT, PSP, CP, VP‡, KO‡	*a* vs *d*

* Substance, S_1, was originally postulated to be coded for by either *bx*$^+$ or *Ubx*$^+$ (ref. 4); in this article S_1 is assigned to *bx*$^+$ and S_0 to *Ubx*$^+$.
† Comparison of genotype *e* and *f* indicates that *bxd*$^+$ and/or *lab-2*$^+$ may be responsible for the continuity of dorsal tracheal trunk in AB1.
‡ Suppression of VP and KO may result from the presence of *lab-8*$^+$ and/or one or more *lab* genes located between *lab-3* and *lab-8*.

0028-0836/78/0276—0565$01 00

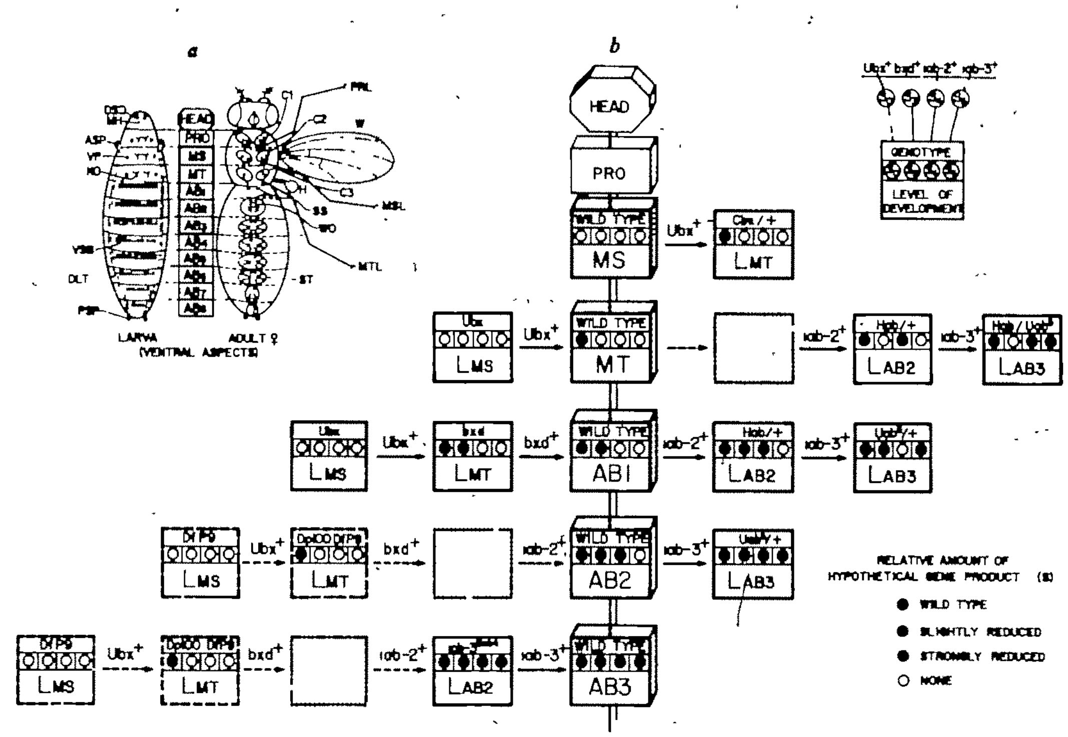

Fig. 1 Genetic control of segmental levels of development in thoracic and abdominal segments. *a*, Anatomy of third instar larva. Head: dorsal sense organs (DSO) and protruding portion of mandibular hooks (MH). Thoracic segments: each bears a pair of Keilin's organs[13] (KO), three sensory hairs in a depression; ventral pits (VP) and ventral setal bands (VSB) with fine tooth-like setae. Abdominal segments: VSB with coarse tooth-like setae; KO and VP lacking. Each dorsal longitudinal trunk (DLT) terminates in an anterior (ASP) and posterior (PSP) spiracle. Anatomy of adult female. Thoracic segments: coxae (C1, C2 and C3) of prothoracic (PRL), mesothoracic (MSL) and metathoracic (MTL) legs; wing (W) and haltere (H), being dorsal, are shown in dotted outline. Abdominal segments: AB1 to AB7 bear sternital sensillae (SS); AB2 to AB7 bear bristled sternites (ST); AB2 has a raised lump, or Wheeler's organ[10] (WO) *b*. Levels of development (L), achieved in wild-type segments (vertical array of connected boxes) and approached in mutant segments, are depicted in panels containing genotype, phenotype and status with respect to relative amounts of hypothetical BX-C substances, S_0, S_3, S_4 and S_5, products of the wild-type alleles of Ultrabithorax (*Ubx*), bithoraxoid (*bxd*), infra-abdominal-2 (*iab-2*) and infra-abdominal-3 (*iab-3*). Panels to the left of wild type depict hemizygous genotypes for hypomorphic or amorphic mutants, the designated chromosome being opposite *Df-P9* (see Fig. 2) in all cases. For simplicity, a slight transformation of the posterior region of AB1 towards LMS in the *bxd* hemizygote is ignored. Panels to the right of wild type involve heterozygotes for hypermorphic (dominant-constitutive) mutants, Contrabithorax (*Cbx*), Hyper-abdominal (*Hab*) and Ultra-abdominal-5 (*Uab*^{5}). Panels in dotted outline represent theoretically possible LAB1 transformations for which definitive mutant genotypes are not available. Panels in dashed outline are genotypes dying in the first instar. All other genotypes shown survive to the adult stage except *Ubx* hemizygotes which die in either third instar or early pupal stages.

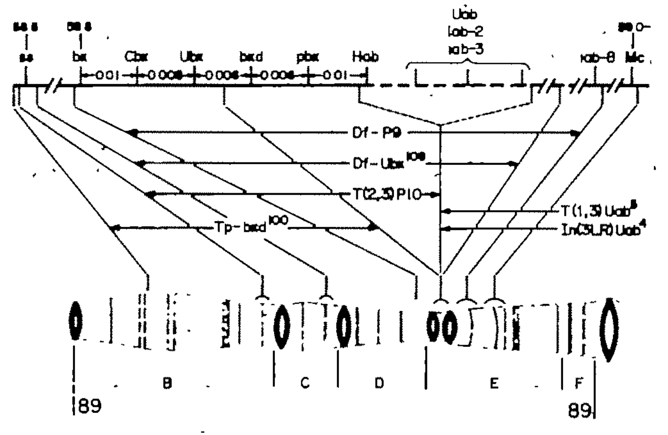

Fig. 2 Correlation of the linkage and salivary gland chromosome maps of BX-C and immediately surrounding regions in the right arm of the third chromosome. The solid line portion of the linkage map is based on half-tetrad[6], as well as on conventional, linkage analysis. The dashed line portion is based on unpublished cytogenetic studies of the designated rearrangements, the relative order of *Hab*, *Uab*, *iab-2* and *iab-3* with respect to each other being uncertain. The complex spans approximately 0.05 to 0.1 centimorgan and lies within the region of two heavy doublet structures and possibly an adjoining faint band of section 89E. Not shown is a spontaneous dominant mutant, Miscadestral pigmentation (*Mcp*), recently found by M. Crosby, which maps between *Hab* and Microcephalus (*Mc*)[15]. *DF-P9* in its interactions with BX-C mutants and rearrangements acts as if it is deleted for all of the BX-C genes. *Df-P9*/+ has reduced male pigmentation in AB5 and AB6, is sterile, and has deformed genitalia in both sexes, which on the basis of other interactions and of larval studies (Fig. 6*d*) behaves as a deficiency extending from *bx* to *iab-3*, associated with a weakened dominance of genes to the right of *iab-3*. *Mc* is apparently a very small tandem duplication which partially restores fertility when *trans* to *Df-P9* but does not otherwise modify the *Df-P9*/+ phenotype. *T(2; 3)P10* is an insertional translocation of the designated region of 89 to section 29C of chromosome 2; the breakage point in 89E is likely on genetic grounds to lie between *pbx* and *iab-2* and to be accompanied by polar position effects that weaken the dominance of *iab-2*$^+$ and *iab-3*$^+$. *Tp(3)bxd*^{100} is a transposition of the designated 89 region to 66C of chromosome 3L; the breakage point lies between *Ubx* and *bxd* and is accompanied by a weakened dominance of *bdx*$^+$ and *pbx*$^+$ (ref. 1) but not, as far as can be detected, of genes to the right of *pbx*. *T(1; 3)Uab*^{5} is a reciprocal translocation with a breakage point in section 1E of the X chromosome; a synthetic deletion analysis indicates that the *Uab*^{5} phenotype is associated with the distal portion of the translocation; that is, the breakage point in 89E lies to the left of *Uab*^{5} and falls either to the left or right of *lab-2*$^+$. *In(3LR)Uab*^{4} is a complex inversion with additional breaks in 80C and in or near 85A or 3R. Analysis of X-ray induced revertants ot *Uab*^{4} indicates that the breakage point in 89E probably lies just to the left or right of *iab-2* and is associated with a weakened dominance of *iab-3*$^+$ (designated in Fig. 1 *iab-3*^{Uab4}) and possibly of *iab-2*$^+$, as well. *Hab* was originally designated as the F locus of the complex[7]; and has also appeared in the literature as Contrabithoraxoid (*Cbxd*). The first two *Uab* mutants found, *Uab* and *Uab*^{2}, although cytologically apparently normal, are associated with a reduction in crossing over within the complex and are accompanied by position effects or point mutations at other loci within BX-C. Their dominant phenotypes resemble that of *Uab*^{4} much more closely than that of *Uab*^{5}. Cellular determination of *Uab* has been extensively studied by Kiger and Davis[20,21].

advanced than LMS is a stepwise process in which each step requires the presence of a specific BX-C substance. In keeping with the model, all of the genotypes involving recessive loss of function lie to the left or LMS side of the wild-type segments while those involving dominant gain of function lie to the right or LAB3 side of those segments.

Segment MT transforms towards LMS even in larval stages of homozygotes[1] and hemizygotes for Ultrabithorax (*Ubx*). The most prominent feature is the occurrence of an extra set of spiracles on MT (and also AB1) (Fig. 3*a*) compared to the usual single set on MS. Although such animals die in late larval or early pupal stages, adult *Ubx*/*Ubx* cuticular tissue in MT has been shown by somatic mosaic analysis to transform autonomously towards LMS[4,8]. A substance, S_0, effecting LMS → LMT, will be assumed to be the *Ubx*$^+$ product. The inability of MT to achieve LMT in *Ubx* hemizygotes or homozygotes is then consistent with the expected reduction in amount of S_0 in that segment. The adult MT cuticle, but not the larval tracheal system, strongly transforms toward LMS in a double mutant combination involving bithorax-3 (*bx*^{3}) and postbithorax (*pbx*), notably producing a four-winged fly[5,8]. Substances S_1 and S_2 are assumed to be the products of *bx*$^+$ and *pbx*$^+$, respectively (Table 1), and to be involved in effecting LMS → LMT; however, for the sake of simplicity, they are omitted from Fig. 1*b*. The wild-type phenotype, on these assumptions, corresponds to that expected if *bx*$^+$, *Ubx*$^+$ and *pbx*$^+$ are repressed in MS and derepressed in MT.

Segment MS takes on MT characteristics in flies heterozygous or homozygous for Contrabithorax (*Cbx*), the most conspicuous effect being a partial conversion of wings into halteres[5,9]. *Cbx* is known to regulate *Ubx*$^+$ in a *cis*-dominant fashion; that is, MS transforms towards LMT in *Cbx* +/+ *Ubx* but is virtually wild type in *Cbx Ubx*/+ +[2,5]. *Cbx* presumably damages a regulatory element adjacent to *Ubx*$^+$ causing S_0 to be made constitutively in MS but in a relatively reduced amount compared with that made in MT when *Ubx*$^+$ is in the wild-type configuration.

Segment AB1 transforms primarily towards LMT in hemizygotes for bithoraxoid (*bxd*), producing flies with one or two MT-like legs on AB1, and on rare occasions a tiny haltere-wing as well[5]. This phenotype has been accounted for by postulating that *bxd*$^+$ codes for a substance, S_3, effecting LMS → LAB1[4]. Evidence to be represented later suggests that *Ubx*$^+$ is derepressed not only in MT but also in AB1 and segments beyond. Hence, in the *bxd* hemizogote, there is presumably enough S_0 in AB1 to transform that segment towards LMT. That AB1 remains at LMS in the *Ubx* hemizygote (Fig. 3*a*) is expected since *Ubx* is known to exert a strong polar effect on *bxd*$^+$ (ref. 1); that is, neither S_0 nor S_3 is expected to be made in sufficient amounts to transform AB1 appreciably towards LMT or LAB1. In wild type, S_0 as well as S_3 is presumably being produced in AB1; although S_3 function may override that of S_0, a more attractive possibility is that LAB1 actually corresponds to a mosaic of structures and functions controlled jointly by S_0 and S_3.

Segments MT and AB1 approach LAB2 in heterozygotes for a second type of dominant regulatory mutant, Hyperabdominal (*Hab*), producing flies with missing halteres and/or MT legs and with an AB2-type of sternite pattern[10,11] on MT and AB1 (Fig. 4*b*). These effects are variably expressed within a fly even though the penetrance of *Hab*/+ exceeds 99% in certain backgrounds.

Cis-trans studies involving all possible double mutant combinations between *Hab* and *bx*^{3}, *Ubx*, *bxd* and *pbx* indicate that *Hab* does not derepress the wild-type alleles of any of these genes. *Hab* will be assumed to cause partial derepression of a wild-type infra-abdominal-2 (*iab-2*$^+$) gene, whose coding product, S_4, effects LMS → LAB2. On this assumption, the wild-type phenotype is that expected if *iab-2*$^+$ is repressed in MT and AB1 and derepressed in AB2. Similarly, the *Hab*/+ phenotype is that expected if *iab-2*$^+$ is partially derepressed in MT and AB1 and fully derepressed in AB2.

The failure of MS to be modified in *Hab*/+ requires explanation. The *Hab* mutation presumably damages a regulatory element adjacent to *iab-2*$^+$ in such a way as to reduce its affinity for a repressor. If there is an entero-posterior concentration gradient in that repressor, then conceivably the threshold concentration for keeping *iab-2*$^+$ repressed in the *Hab* chromosome is exceeded in MS but not in MT and segments beyond MT.

Segments AB1 and AB2 partially transform toward LAB3 in adults heterozygous for Ultra-abdominal-5, *Uab*^{5}, a third type of dominant constitutive mutant, inseparable from an X-3 translocation (Fig. 2). The transformation is most easily seen in the ventral regions of AB1 and AB2 which develop sternite patterns approaching those found in AB3 (Fig. 4*c*). The effect on AB2 can be accounted for if *Uab*^{5} derepresses a gene, *iab-3*$^+$, which codes for a substance, S_5, effecting LAB2 → LAB3. The wild-type pattern then corresponds to that expected if *iab-3*$^+$ is repressed in AB1 and AB2, but derepressed in AB3. The penetrance of *Uab*^{5}/+ is complete but the transformation of AB1 towards LAB3 is variable with that segment often progressing only towards LAB2. If, as certain larval findings discussed below suggest, *iab-2*$^+$ is normally weakly derepressed in AB1, then the presence of S_4 in AB1 even in subthreshold amounts may facilitate the transformation to LAB3 in *Uab*^{5}/+. Another possibility is that the *Uab*^{5} rearrangement in some way partially derepresses *iab-2*$^+$ as well as *iab-3*$^+$; however, although MT transforms to LAB2 in *Hab*/+, MT is not modified in *Uab*^{5}/+.

Segment MT is able to approach LAB3, along with AB1 and AB2, in *Hab*/*Uab*^{5} animals (Fig. 4*d*). Transformation to LAB3 in MT thus seems to require two sequential steps: LMS → LAB2 → LAB3, the former controlled by S4 and the latter by S_5. The observed transformation of all three segments towards LAB3 is readily accounted for, since both S_4 and S_5 are expected to be produced in MT, AB1 and AB2 of *Hab*/*Uab*^{5}.

Additional evidence for an *iab-3*$^+$ gene comes from an analysis of another rearrangement-associated *Uab* mutant, *Uab*^{4}. When heterozygous, *Uab*^{4} shows a dominant gain of function in which AB1 partially transforms towards LAB2. When hemizygous, or opposite *T(2; 3)P10* (Fig. 2), *Uab*^{4} exhibits a new type of recessive loss of function; namely, the sternites of not only AB1 but AB3 to AB6, inclusive, transform towards LAB2 (Fig. 3*c*). These latter effects are attributed to a reduction in the amount of S_5 which would be expected if the *Uab*^{4} and *T(2; 3)P10* rearrangements are accompanied by position effects on *iab-3*$^+$.

Gonads, normally located in AB5, are absent in *Uab*^{4} hemizygotes, suggesting that BX-C genes control mesodermal as well as ectodermal tissues. Gonadal examination of *Uab*^{4} genotypes was prompted by the report of gonadal defects in homozygotes for certain *Uab*-like mutants of the homologous 'E-locus' complex of Bombyx (see review by Tazima[12]).

Segment AB4 transforms strongly towards LAB5, both in pigmentation and bristle patterns in heterozygotes and homozygotes for Miscadestral pigmentation (*Mcp*), a dominant mutant recently discovered by M. Crosby (unpublished). Analysis of X-ray induced revertants indicates that *Mcp* probably derepresses a gene, *iab-5*$^-$, which codes for a substance, S_7, effecting either LAB4 → LAB5 or LMS → LAB5.

A new dimension has been added to the analysis of BX-C with the discovery that a homozygous deficiency for the entire complex, *Df-P9* (Fig. 2) survives to the late embryonic or early first instar stage and exhibits a transformation of MT and all eight AB segments towards LMS. Pairs of Keilin's organs[13] (KO), ventral pits (VP) and thoracic-type ventral setal bands (VSB) appear on those segments (Fig. 5*a* and 5*b*) and in place of a continuous dorsal longitudinal tracheal trunk (DLT) each segment bears a section of DLT terminating presumably in an incipient anterior spiracle (ASP)[14] (Fig. 5*c*, vs. *d*); finally, the ventral nerve cord tends to retain its primitive embryonic pattern in that it extends to segment AB6 or AB7 instead of foreshortening to segment AB3 or AB4 as in wild type. Tiny

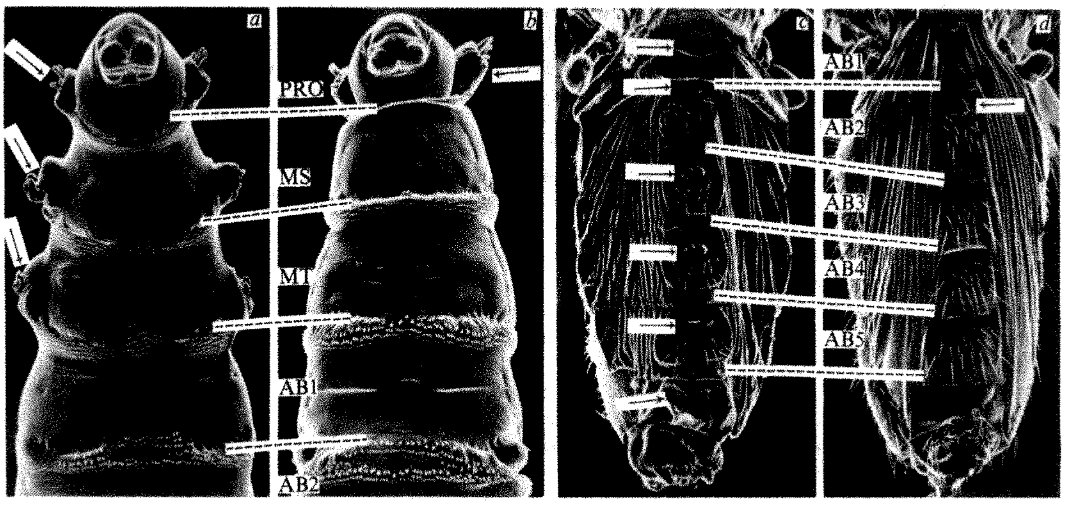

Fig. 3 Mutant phenotypes resulting from recessive loss of function compared with wild type. See Fig. 1(*a*) for legend. *a*, Late third instar larva hemizygous for *Ubx* (*Ubx/Df-P9*). Note extra pairs of anterior spiracles (ASP) (arrows) on MT and AB1, protruding into MS and MT, and thoracic type of ventral setal bands (VSB) on AB1 compared with abdominal type on AB2. *b*, Corresponding stage of homozygous wild-type (Canton-S) larva. Note single pair of ASP (arrow) which arises in MS but protrudes into the region of the prothorax (PRO). Note setae of VSB are coarse in AB1 and AB2, fine in MS, and intermediate in MT. (Specimens *a* and *b* were fixed in hot water and photographed with SEM, X40. *c*, Ventral aspect of male abdomen of genotype *In(3LR)Uab*^{4}*/T(2; 3)P10* (see Fig. 2). Note presence of WO (arrows) and sternital bristle pattern of AB2 type on segments AB1 through AB5. Gonads are rudimentary in specimens of this genotype or lacking entirely in *Uab*^{4}*/Df-P9*. *d*, Corresponding region of adult wild-type (Canton-S) male. Note that AB1 lacks a sternite and that only AB2 (arrow) has WO. (Specimens *c* and *d* were unfixed and photographed with SEM, ×50.)

chitinised plates (CP), resembling rudiments of mandibular hooks (MH), occur in AB8 and imply a head-like rather than LMS transformation of one or more of the embryonic segments that normally fuse to form AB8.

In order to delineate regional differences in morphological functions within BX-C, hemizygotes for deficiencies of portions of BX-C have been constructed. Figure 6 displays stylised phenotypes associated with genotypes hemizygous for five such deficiencies (*b–f*), for *Df-P9* (*a*), for *bxd* (*g*) and for wild type (*h*).

A direct demonstration that *Ubx*$^+$ effects LMS → LMT can be seen by comparing genotypes *a* and *b*, which lack all BX-C genes except that *b* retains one dose of *Ubx*$^+$ (and *bx*$^+$). All nine segments from MT to AB8 remain at LMS in *a* and attain LMT in *b*; that is, in *b* they acquire a pattern of attributes unique to the larval MT (namely, a continuous DLT, VP, KO and thoracic-type VSB). Furthermore *Ubx*$^+$ behaves as if derepressed not only in MT and AB1, but in the remaining abdominal segments as well. That many other BX-C genes share with *Ubx*$^+$ the ability to establish continuity of DLT is evidenced by the presence over several segments of continuous DLT in larval genotypes, *d*, *e* and *f*, which lack *Ubx*$^+$ but have one or more other BX-C genes still present.

All abdominal segments approach, but do not quite achieve, LAB1 in animals of genotype *c*, which is a hemizygote for *bxd*$^+$ (and *pbx*$^+$) as well as *Ubx*$^+$. Such animals are seen to have most of the characteristics of wild-type AB1 (absence of ASP and VP and presence of DLT and VSB, but incomplete suppression of KO). Failure of *bxd*$^+$ to effect a perfect transformation to LAB1 is not understood. One possibility is that *iab-2*$^+$ and *bxd*$^+$ are

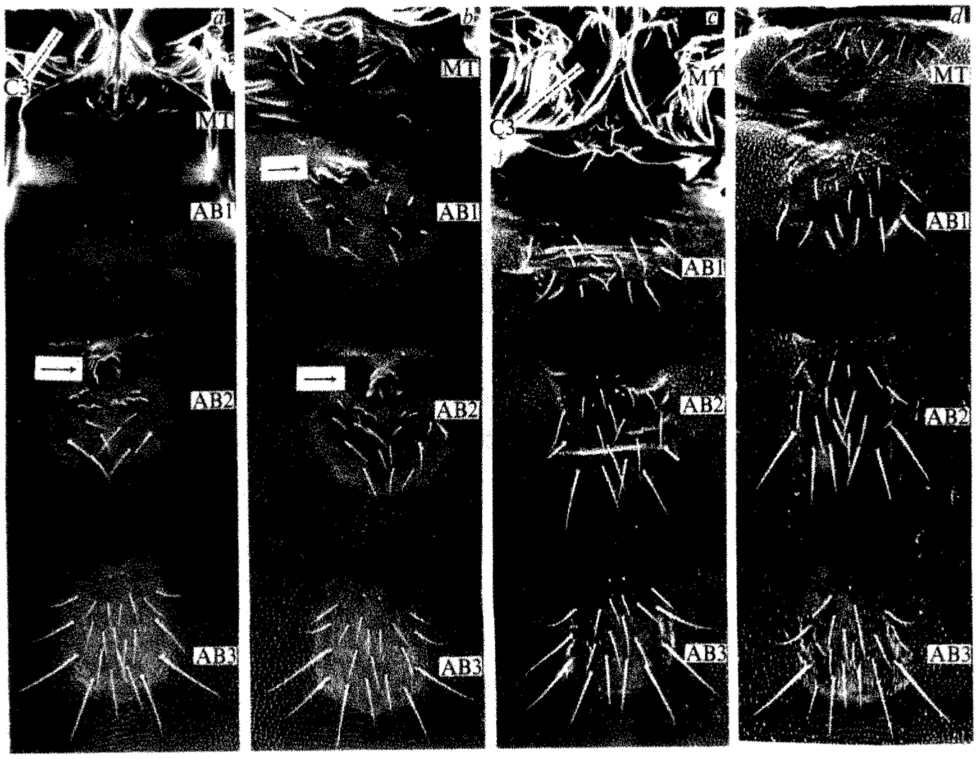

Fig. 4 Mutant phenotypes resulting from dominant gain of function compared with wild type. Mid-ventral cuticular regions of adults female with MT, AB1, AB2 and AB3 approximately parallel to one another. (All specimens unfixed and photographed with SEM.) *a*, Wild type. A portion of coxa-3 (C3) is visible on MT; AB1 lacks a sternite; AB2 has WO (arrow) and a reduced (compared to AB3) sternital bristle pattern, ×80. *b*, *Hab/+*. The specimen had four legs and no halteres. WO (arrows) and bristle pattern on MT and AB1 approach those of Ab2, ×80. *c*, *Uab*^{5}*/+*. C3 resembles that of wild type. AB1 and AB2 sternites lack WO and approach in bristle pattern that of AB3, ×90. *d*, *Hab/Uab*^{5}. The specimen had four legs and no halteres. Sternites on MT, AB1 and AB2 have little or no trace of WO and approach in their bristle patterns that of AB3, ×80.

both involved in the suppression of KO and that *iab-2*$^+$ is weakly derepressed in AB1 (depicted in Fig. 6*h* by indicating a strongly reduced amount of S_4 in that segment of wild type). Complete suppression of KO can occur in genotypes which lack full *bxd*$^+$ function; namely, *f* and *g*. In such cases, it seems likely that *iab-2*$^+$ and possibly *iab-3*$^+$ are able to bring about suppression of KO when fully derepressed.

Suppression of VP seems to be exclusively controlled by *bxd*$^+$, these organs being absent from abdominal segments only when *bxd*$^+$ is present, as in genotypes *c* and *h*. It is therefore directly evident from *h* that *bxd*$^+$ is normally derepressed not only in AB1, but in all segments posterior to AB1.

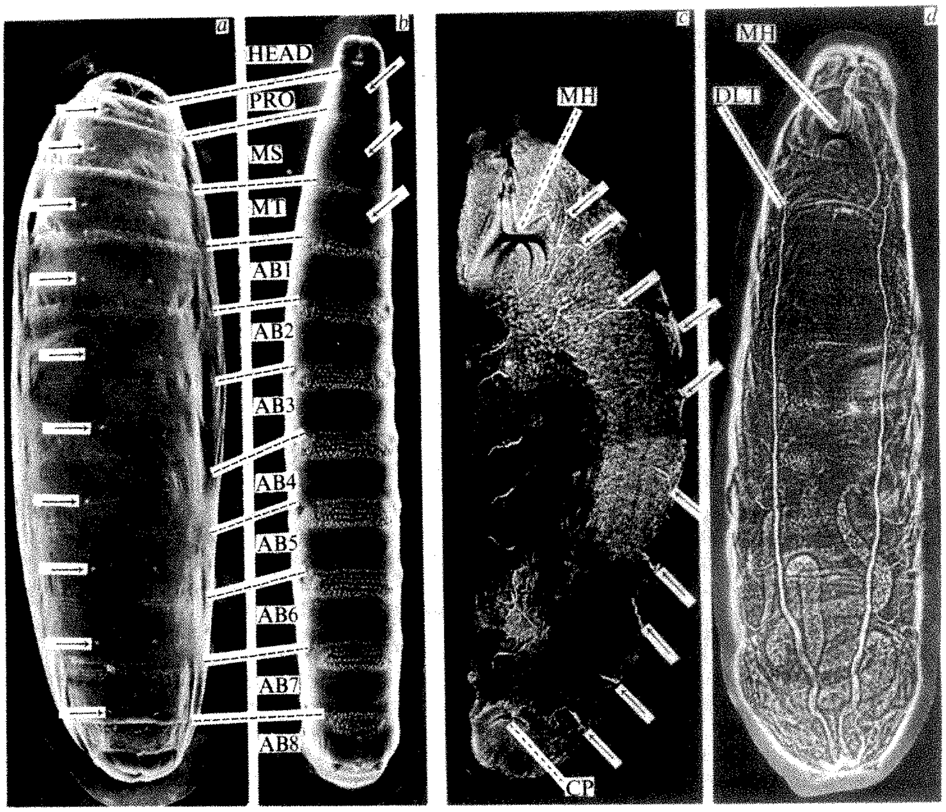

Fig. 5 Comparison of cuticular and tracheal patterns in homozygotes for a deletion of BX-C (*a* and *c*) compared with those of wild type (*b* and *d*). See Fig. 1 for legend. *a*, *Df-P9* homozygote. Animals die within the egg or after partly emerging from egg membranes. Note thoracic-like VSB, KO (arrows) on segments AB1 through AB7, as well as on thoracic segments; AB8 has a reduced VSB. KO not visible in AB8 of specimen shown but are visible in whole mounts examined under phase contrast, ×160. *b*, Wild-type first instar larva. Note more prominent VSB on abdominal vs. thoracic segments, with VSB on MT somewhat intermediate between those on MS and AB1. KO (arrows) are restricted to thoracic segments as are also VPs, which are not resolved at the magnification shown, ×60. (Specimens *a* and *b* were fixed in hot water and photographed with SEM.) *c*, Whole mount of mature embryo of *Df-P9* homozygote. Note separate tracheal sections (arrows) of DLT occur in each segment from MS through AB8, and tiny chitinized plates (CP) in AB8. *d*, Whole mount of wild-type first instar larva. Note continuous DLT. (Specimens *c* and *d* mounted in Zeiss W15 medium and photographed under phase contrast, ×120.)

The larval effects of *iab-2*$^+$ can be indirectly inferred by comparing tracheal and cuticular patterns in AB2 of genotypes *d*, *e* and *f* (Fig. 6), which involve loss, weakened dominance and dominance, respectively, of *iab-2*$^+$. Continuity of DLT is seen in both *e* and *f*, suppression of KO occurs only in *f*, and VSB become progressively more abdomen-like in proceeding from *d* to *e* to *f*. These effects are not necessarily solely due to the *iab-2*$^+$ gene since it is possible that *iab-3*$^+$ is weakly derepressed in AB2 of the larva. Unfortunately, definitive genotypes are not available that would resolve *iab-2*$^+$ and *iab-3*$^+$ larval functions.

A comparison of larvae of genotypes *a* and *d* (Fig. 6) shows that the latter retain the wild-type cuticular pattern in AB8 (except for thoracic-type VSB) and have DLT continuity between AB7 (or AB6) and AB8. These effects are most simply accounted for by assuming that in contrast to *Df-P9*, *Df-Ubx*^{109} still retains an *iab-8*$^+$ gene, whose product, S_x, effects LAB7 → LAB8 or LMS → LAB8. The ability of genotype *d* to restore a tracheal trunk in the region from AB6 to AB8 suggests that *Ubx*^{109} retains additional *iab* loci to the right of *iab-3*, besides *iab-8*.

The above findings point to an antero-posterior gradient within the organism in BX-C gene action. A regulatory gene(s) might therefore be expected to exist which, when activated, would derepress or activate BX-C genes in all segments of the body. The properties of Polycomb (*Pc*), a mutant found by P. H. Lewis[15], and of a more extreme allele, *Pc*^{3}, suggest that *Pc*$^+$ (locus 3-47.1)[16] is such a gene. Thus, hemizygotes and homozygotes for *Pc* or *Pc*^{3} have recently been found to have their thoracic and first seven abdominal segments partially transformed towards LAB8. Such animals, which die as late embryos, also have reduced head structures, including poorly developed and incompletely sclerotised MH. As the doses of BX-C are increased from two to three to four, the transformation towards LAB8 becomes increasingly more extreme with many of the abdominal segments containing rudimentary posterior-type spiracles. The LAB8 transformation is not observed unless at least one dose of BX-C is present; that is, *Pc*^{3} *Df-P9* homozygotes closely resemble *Df-P9* homozygotes (Fig. 5) except that the former have reduced head structures and incompletely sclerotised CP in AB8 (suggesting that the latter structures are indeed rudiments of MH). A dependence of BX-C phenotypic effects on BX-C dosage is seen also in *Pc*^{3} heterozygotes: for example, *Cbx*-like effects occur in *Pc*^{3}/+ animals (with two doses of BX-C) and become increasingly more extreme with three and four doses of BX-C. Gene dosage studies of R. Denell (personal communication) indicate that *Pc* represents the inactivated state of the gene. Therefore, *Pc*$^+$ in all likelihood is coding for a repressor of BX-C.

Regulatory rules

The BX-C genes are assumed to control the organism's thoracic and abdominal segmentation pattern by producing substances which in turn regulate other genes that actually determine segmental structure and function. Regulation of the BX-C genes, themselves, seems to be governed by the following rules: (1) state of repression or derepression of a given gene is controlled (in at least four instances) by a *cis*-regulatory element; (2) the genes tend to be individually, rather than coor-

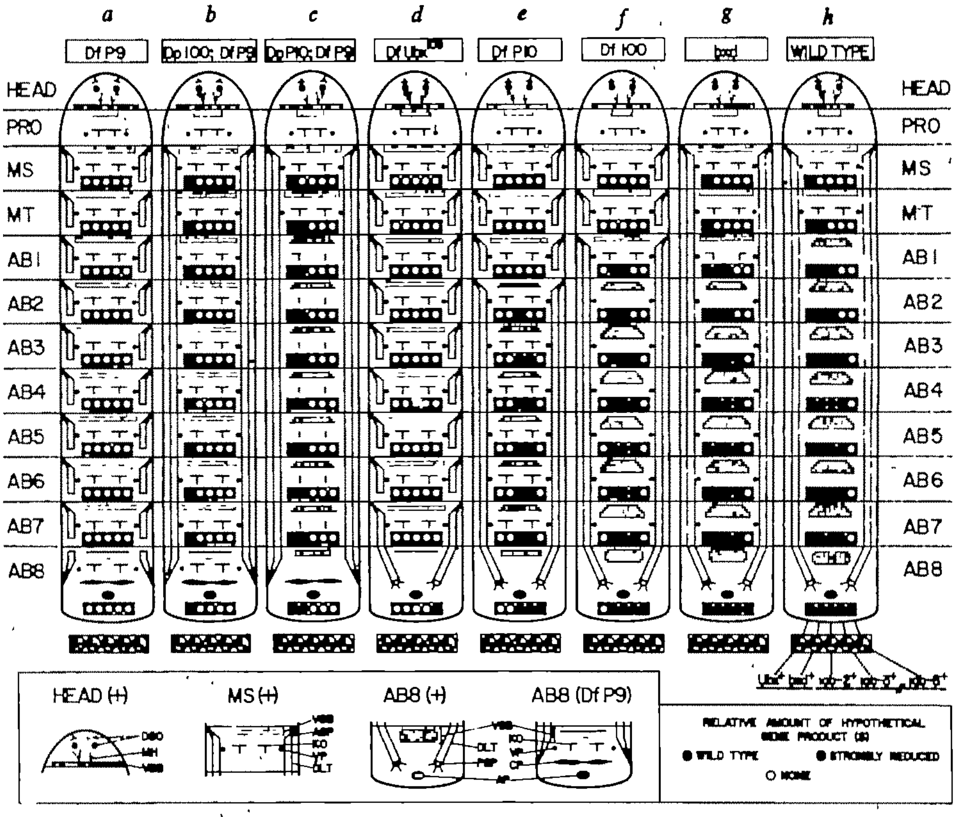

Fig. 6 Stylised phenotypes detectable in first instar larvae or mature embryos. See Fig. 1(*a*) for legend, Fig. 2 for description of rearrangements and Table 1 for roles of postulated BX-C substances (S). All drawings based on whole mounts of animals examined with phase contrast microscopy. Mounting fluid: 9 parts lactic acid to 1 part 95% ethanol for revealing cuticular structures; and Zeiss W15 for tracheal structures. *a*, *Df-P9* homozygote (see also Fig. 5*a* and *c*). *b*, *Df-P9* homozygote containing one dose of *Dp-100*, abbreviated symbol for the duplication derived from *Tp(3)bxd*^{100} (Fig. 2). Note identity to *a* except for presence of DLT *c*, *Df-P9* homozygote containing one dose of *Dp-P10*, abbreviated symbol for the duplication derived from *T(2; 3)P10* (Fig. 2). Note suppression of VP and partial suppression of KO in segments AB1 to AB7. Although VP and KO appear to be absent in AB8, they may be obscured by CP and other structures in that segment. *d*, *Df-Ubx*^{109}/*Df-P9*. Note DLT between segments AB7 and AB8, and presence of PSP in AB8; and absence of CP in AB8; occasionally DLT also forms between AB6 and AB7. *e*, *Df-P10/Df-P9*. *Df-P10* is an abbreviated symbol for the deficiency derived from *T(2; 3)P10* (Fig. 2). DLT restored in AB2 through AB8. The pair of separate sections of that trunk in AB1 frequently lie in AB2, parallel to DLT in that segment. Note partial restoration of abdominal-type VSB, weakly developed in AB2 and moderately developed in AB3 through AB8. *f*, *Df-100/Df-P9*. *Df-100* is an abbreviated symbol for the deficiency derived from *Tp(3)bxd*^{100} and has moderately weakened dominance of *bxd*$^{+}$ as a position effect of the 89E breakage point. Note retention of DLT and failure of suppression of VP in AB1 through AB7 (with VP status in AB8 uncertain) and full restoration of abdominal type of VSB in all segments from AB2 through AB8. *g*, *bxd/Df-P9*. Although not deleted for any known genes of BX-C this genotype is depicted since it has effects on several larval (as well as adult) cuticular structures. Note failure of suppression of VP on AB1 through AB7; thoracic-type VSB on AB1; and only partial suppression of KO on AB1. *h*, Wild-type homozygote or hemizygote (the latter having possibly somewhat narrower VSB on AB segments than the former) (see Fig. 5*b* and *d*). All individuals of genotype *a* through *f* die in the late embryonic or early first instar stage. ASP are lacking in first instar larvae according to Bodenstein[14]. Separate sections of DLT send out a branch to the cuticle but no anterior spiracles as such have been resolved. A number of larval phenotypic expressions are not readily explained unless it is assumed that there is weak derepression of *Ubx*$^{+}$ (to establish continuity of DLT between MS and MT), *bxd*$^{+}$ (to make very slightly larger VSB teeth in MT than MS) and *iab-2*$^{+}$ (to suppress KO in AB1) in the segment anterior to that in which each is fully derepressed. Whether *iab-3*$^{+}$ or *iab-8*$^{+}$ are also similarly weakly derepressed is uncertain.

dinately, derepressed; (3) BX-C is under negative control maintained by a major regulatory gene, *Pc*$^{+}$ (along with perhaps other regulatory genes[7,17]); (4) a gene derepressed in one segment is derepressed in all segments posterior thereto; (5) the more posterior the segment (starting with MT) the greater the number of BX-C genes that are in the derepressed state; and (6) the more proximal the locus of a gene in the complex the more likely it is that that gene is in a derepressed state. Rules (5) and (6) suggest that two types of gradient are involved in BX-C regulation: an antero-posterior gradient within the organism in repressor concentration and a proximo-distal gradient along the chromosome in relative affinity for repressor of *cis*-regulatory elements. Presumably in MT repressor concentration is so high that the only genes derepressed are those whose *cis*-regulatory elements have relatively low repressor affinities, while in AB8 repressor concentration is so low that all of the genes of the complex escape repression.

During ontogeny the above rules presumably result in each segment having a specific array of BX-C substances, at the right time, at the right place. In AB8, for example, the rules predict a minimum of eight such substances, the number of BX-C genes being very likely to exceed the eight identified thus far. Whether such a multiplicity of substances act in a hierarchical or a compartmentalised manner[18,19] to establish the final pattern or level of development of a segment may well be accessible to analysis at the cellular level.

I thank Françoise Bacher, Terri Chamberlain, Madeline Crosby, Nancy Hwang, Nancy Shaw and Gudrun Vener for assistance and Dr Loring Craymer for helpful discussions. This work was supported by USPHS grant HD 06331B.

Radio observations of point sources are presented which may be the stellar remains of supernovae. In particular 1909+048 is described, a source which has also been detected in the optical and X-ray ranges.

THE stellar remnants of the Crab and Vela supernovae are detectable over a wide frequency range (radio through optical to X rays) as pulsars showing the short period (<1 s), presumably caused by fast rotation, in all observations. Although it has commonly been assumed that the stellar remnants of all supernovae form pulsars, there have been indications that stellar remnants may sometimes be detectable as non-pulsing radio sources. In particular: (1) Clark *et al.*[1] questioned whether Cir X-1 (with its associated non-pulsing radio source 1516−569) might be the stellar remnant of the supernova which formed the nearby radio shell SNR (supernova remnant) G321.9−0.3; (2) the point radio source 2048+312 (CL4), in the direction of the Cygnus Loop, may be associated[2] with the SNR; (3) an unusual point source 0125+628 at the centre of the SNR G127.1+0.5 may be[3] the stellar remnant of this supernova. This source has a flat spectrum[4] between 2.7 and 15 GHz, while its angular size is <1 m arc s and may be much less[5].

We have recently investigated the point radio source 1909+048 in W50 and have concluded that it certainly represents a distinct new type of radio source. We discuss here this object and some other possible examples for which we have preliminary measurements.

1909+048—the stellar remnant of the SNR W50?

The extended radio source W50 (G39.7−2.0) was recognised as an SNR by Holden and Caswell[6]. More recent data[7,8] confirm that it has a shell structure and reveal a point source near its centre; a small-diameter X-ray source (W50X) has also been reported near this direction[9,10]. We have used the Cambridge 5-km radio telescope at 2.7 and 15 GHz to study this point

source, and have found that the angular size is extremely small, the mean spectrum is relatively flat, and that the flux density varies dramatically at high frequencies (Fig. 1). Since this paper was completed, Seaquist *et al.*[11] and Feldman *et al.*[12] have also reported observations of the radio variability, and have noted that the optical object is No. 433 in the list of Hα-emission objects by Stephenson and Sanduleak[13]. An accurate position has also been measured (Table 1). The unusual nature of the radio/X-ray source and its position near the centre of the SNR shell strongly suggest that it is the stellar remnant of the supernova. A stellar object is indeed visible on the Palomar Observatory Sky Survey prints which coincides with the radio source to within the limits of error. The optical field is a crowded one, but the star in question is the brightest in the vicinity of the radio source. The estimated magnitudes are $m = 12.4 \pm 0.5$ on the E print and $m = 16.7 \pm 0.5$ on the O print. Clearly, it will be important to obtain an optical spectrum of this star[14], and to investigate the X-ray properties in greater detail.

A comparison of the distances of the point source and the shell SNR is obviously desirable. In the case of the point source, an HI absorption measurement is needed, but for the SNR we have estimated the distance from the Σ-D relation of Caswell and Lerche[15]. In reaching this estimate we first reassessed the radio data and adopted a spectral index $\alpha = 0.45$ (where $S \propto \nu^{-\alpha}$), S(408 MHz) = 65 Jy and elliptical major and minor axes of 81 and 45 arc min respectively. The corresponding surface brightness at 408 MHz, $\Sigma = 2.72 \times 10^{-21}$ W m^{-2} Hz^{-1} sr^{-1}, yields a distance of 3.3 kpc.

There is also a second point source (1910+052) within the shell of W50 which seems to be of the same type. It is included in Tables 1 and 2, and is discussed later.

Properties of the new class of source

Tables 1 and 2 list the candidates already mentioned, together with some further possibilities. Table 1 gives positions, as measured with the 5-km telescope except in the cases of 1347−617 and 1516−569, and also positions of optical objects which may be associated. In the case of 1909+048, the optical position has been newly measured from the Palomar Observatory Sky Survey prints, with respect to stars from the Smithsonian Astrophysical Observatry catalogue. Table 2 lists the flux densities at 1.4 GHz, angular diameters (from the 5-km observations if not otherwise noted), spectral indices, variability (see Fig. 1), estimated distances of the SNRs (derived from the Σ-D relationship of Caswell and Lerche[15], except for G74.9+1.2), and associations with SNRs.

From a consideration of the four candidates, 0125+628, 1516−569, 1909+048 and 2048+312, we suggest the following characteristic properties of this class of source: (1) small diameter; (2) variability at high frequencies; (3) flat spectrum at high frequencies; (4) association with an SNR. In general a position near the centre is expected unless the object has a large space velocity. If the lifetime of these compact radio emitters is greater than that of the shell remnants, however, it is evident that there will be many without associated shells, as in the case of the radio pulsars. (5) Possible X-ray and/or optical counterparts.

In addition to the four sources already considered, Tables 1 and 2 list the properties of five other sources which have been found near SNRs and which we also regard as possible members of the new class. Some additional details of the sources, not previously mentioned, are as follows.

0125+628. From a small number of observations, Salter *et al.*[4] detected no variations at 5 GHz, but it is clear from Fig. 1 that the flux density at 15.4 GHz is varying on a timescale of a month, and perhaps much faster, although the significance of the more rapid variations is not large. Figure 1 suggests that $\alpha_{2.7}^{15} \approx -0.2$ in 1977 May, and the flux values at 2.7, 8.1 and 10.6 GHz quoted by Shaffer *et al.*[5] also confirm the flatness of the spectrum above about 2 GHz. There is a cut-off at lower frequencies.

0503+466. Point source in HB9, with S(2.7 GHz) = 590 mJy (ref. 21). It is absent from the 4C records but has been detected in the 6C survey[22] with S(150 MHz) = 740 ± 250 mJy in 1976 May (Masson, personal communication). Its spectrum is therefore very flat.

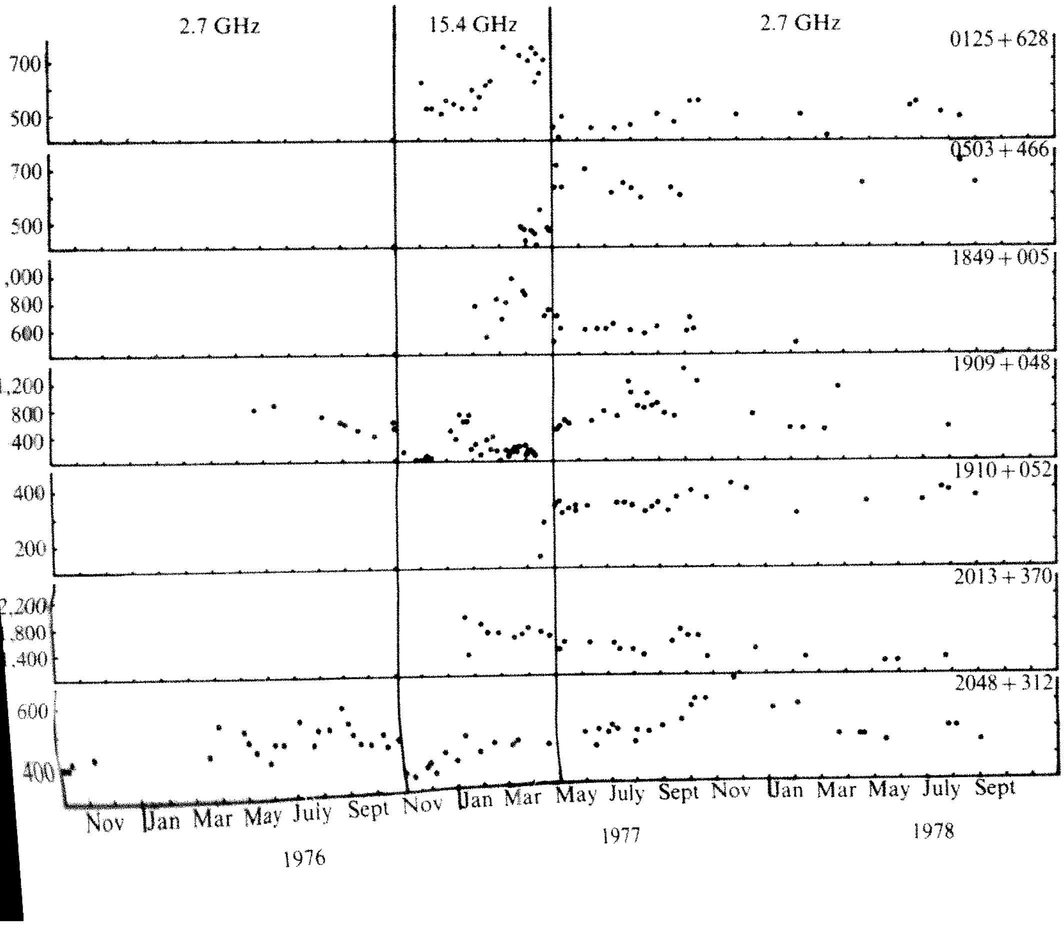

Fig. 1 Flux densities as measured with the 5-km telescope at 2.7 GHz (October 1975–October 1976, and May 1977–September 1978) and 15.4 GHz (November 1976–April 1977). Linearly polarised feeds were used with the E-vector in position angle 90°. The calibration assumed flux densities S(2.7 GHz) = 13.0 Jy for 3C147, and S(2.7 GHz) = 10.3 Jy, S(15.4 GHz) = 3.69 Jy for 3C286. The main contributions to errors are from receiver noise (~3 mJy at 2.7 GHz, and 20 mJy at 15.4 GHz) and tropospheric variations (<3% at 2.7 GHz, and <5% at 15.4 GHz).

Table 2 Candidate flux densities and other data

Source	S(1.4 GHz) mJy	Angular diameter 10^{-3} arc s	Spectral Index	Variable	SNR distance estimate (kpc)	Nearby SNR	Refs
0125+628	380	≈0.5	$\alpha_{2.7}^{15} = -0.2$	Yes	5.4	At centre of G127.1+0.5 (R5)	3, 5, 19, see text
0503+466	≈600	<150±130	$\alpha_{2.7}^{15} \approx 0.2$	Yes	1.8	At edge of G160.5+2.8 (HB9)	See text
1347−617	230	>15 000	$\alpha_{0.4}^{1.4} = 0.71$	?	8.1	Near centre of G309.8+0.0	See text
1516−569 (Cir X-1)	380	—	$\alpha_{0.4}^{5} \approx 0.25$	Yes	8	Near G321.9−0.3	1, 17, 20
1849+005	≈800	<130±130	$\alpha_{1.4}^{15} \approx 0.1$	Yes	9.4	Near G33.6+0.1	See text

2013+370	1150	≈0.5	$\alpha_{2.7}^{15} \approx 0$	Yes	>12	Near G74.9+1.2	See text; 19
2048+312 (CL4)	380	≈1	$\alpha_{1.4}^{15} \approx 0.21$	Yes	1.2	Within G74.0−8.5 (Cyg Loop)	2, 19

1347−617. This source is listed tentatively, on the grounds of its position very near the centre of the SNR G309.8+0.0. It contrasts with the other sources by apparently having a steeper spectrum, but flux variability might be responsible.

1849+005. This source was first noted by Caswell *et al.*[23] while mapping the SNR G33.6+0.1, and attention was also drawn to it as a possibly unusual galactic source by Caswell *et al.*[24]. The spectral index quoted in Table 2 is based on a 5-km value of S(15 GHz) = 700 mJy.

1909+048. Figure 1 shows that this is highly variable, especially at 15 GHz. At epoch 1976.9, for example, S(15 GHz) < 20 mJy but, within two months, S(15 GHz) was 740 mJy.

1910+052. This second point source within the shell of W50 was first detected with S(408 MHz) = 780 mJy in 1974. Like 1909+048, it has a small angular size, a flat spectrum and is almost certainly variable at 2.7 GHz (Fig. 1). There were two measurements at 15.4 GHz; these indicated a stronger variability but this requires confirmation. The flux density was also measured at Parkes, New South Wales as S(5 GHz) = 430 mJy in May 1974 and S(15 GHz) = 230 mJy in 1977 August. The occurrence of this second point source within a single SNR shell may be a chance superposition. It is clear that more statistical data on the spatial density of such point sources are required before we can evaluate this possibility.

2013+370. This region has been studied by Duin *et al.*[25] and Shaffer *et al.*[5] The point source lies about 7 arc min outside the SNR boundary so, if the association is real, a high velocity of ejection (>5,000 km s^{-1}) would be necessary to account for the separation. HI absorption measurements[26] place similar lower limits (of ~12 kpc) on the distance of both objects. Whereas the extended source is almost certainly a galactic SNR, present evidence does not rule out an extragalactic nature for the point source. The spectrum is, nevertheless, unusual by any standards, with a low frequency cut-off at the very high frequency of 7.5 GHz.

Discussion

Most of the sources investigated probably represent an important new class of radio star. The relationship of these sources to the other galactic X-ray sources and to pulsars is not yet clear although, if either 1909+048 or 1516−569 is indeed a member of the new class, then the other galactic X-ray binary systems (with or without detectable radio emission) may, in some cases at least, also be the stellar remnants of supernovae, perhaps having outlived their SNR shells.

It has been proposed[27] that all supernovae are formed in binary systems; this would be consistent with the X-ray binary stars originating in supernovae, and may indicate that the radio pulsars are generally confined to those binary systems which have been disrupted by the supernova explosion (in particular, the two pulsars definitely associated with SNRs are not binary systems). If sources of the type discussed here are associated with binary systems not disrupted by the explosion, one may expect periodicities in the radio variations. Webster & Ryle[2], in fact, suggested that the flux variations of 2048+312 are quasi-periodic with a period of ~60 d; we have carried out a power-spectrum analysis on all the available observations. This did not confirm the suggestion but, because of the irregularity of the observations, we cannot reject it either.

A major problem is that the radio properties of the new class are superficially similar to those of some extragalactic sources, the BL Lac objects, and it is indeed possible that some of our suggested examples of stellar remnants may be misidentified. Nevertheless, there can be no doubt that both types of source exist—some, such as the radio counterpart of Cir X-1, being definitely galactic, and others such as the BL Lac objects showing large redshifts, being definitely extragalactic.

We thank Dr B. Elsmore for providing the 5-km radio positions, C. R. Masson for the 150-MHz flux density of 0503+466, and Dr D. Wills for the optical position of the candidate identification for 0125+628, also Drs J. E. Baldwin, P. A. G. Scheuer and A. S. Webster for valuable comments.

Note added in proof—A spectrum[28] of the possible optical counterpart of 0125+628 reveals a faint galaxy. Thus if the radio–optical association is valid, this radio source is not galactic and its coincidence with the SNR is by chance. A red object[29] of 21 mag coincides with the radio source.

K–Ar age of the late Pleistocene eruption of Toba, north Sumatra

The late Pleistocene eruption of Toba is the largest magnitude explosive eruption documented from the Quaternary. K–Ar dating of the uppermost unit of the Toba Tuff gives an age of ~75,000 yr. A chemically and petrographically equivalent ash layer in deep-sea cores helps calibrate the Stage 4–5 boundary of the standard oxygen isotope stratigraphy. A similar ash in Malaya that overlies finds of Tampan Palaeolithic tools indicates that they are older than 75,000 yr.

A WIDESPREAD volcanic ash layer has been found in piston cores taken in the north-east Indian Ocean and the Bay of Bengal, where it occurs in the upper 12 m of sediment. This ash layer has been correlated from core to core on the basis of mineralogy[1]. A study of the area distribution, thickness, grain size and volume of the deep-sea ash layer has shown that the ash originated in an eruption an order of magnitude larger than any other documented for the Quaternary[2] and indicates a source of the ash in an eruption of Toba, north Sumatra[1,2]. Toba caldera, whose dimensions are 100 × 30 km, is surrounded by rhyolitic tuffs (Fig. 1) which occupy an area of 20,000–30,000 km^2 and have a thickness of several hundred metres (refs 3, 4). We report here on the radiometric dating of the Toba Tuff and the correlation of this eruptive.

Several samples of Toba tuffs have been dated. A sample from the base of the tuff series has been dated by the K–Ar method at 1.9 Myr (ref. 5). Three other samples have been dated by the fission-track method: samples of 'old tuff' and 'upper tuff' from the Prapat area gave 1.2 and 0.1 Myr respectively. A third sample of 'welded tuff' from the area of Si Gura Gura gave an age of 0.1 Myr (ref. 6).

A K–Ar age of $75 \pm 12 \times 10^3$ yr on biotite has been reported[7] from a Toba welded tuff sample Id 680. We report here the data on the K–Ar dating and on the chemical and mineraological composition of sample Id 680 from Si Gura Gura and a sample of pumice tuff (72–0–60) from the Prapat area. We have also analysed chemically and mineralogically an ash layer which occurs in 15 deep-sea cores to the west and north-west of Toba (Fig. 1). We have established the position of the ash layer in one of the cores in the standard oxygen isotope stratigraphy, confirmed by two biostratigraphic data, to the extinctions of the radiolarian *Stylatractus universus* and coccolith *Pseudoemiliania lacunosa*. We have also analysed several samples of ash from the Kota Tampan area in west Malaya.

Toba tuffs

The welded tuff sample Id 680 (from the collection of Dr M. T. Zen) came from Si Gura Gura (Fig. 1), along the Asahan River, and was taken at a depth of 55 m.

The tuff consists of about 47% crystal fragments embedded in a matrix of fine crystalline material and volcanic glass. The composition of heavy minerals is given in Table 1. Only a few phenocrysts of allanite, reported by Westerveld[8], have been identified in the studied sample. Opaque minerals are rare, and are mostly developed as secondary products on grain borders or within xenoliths. Xenoliths are abundant in the form of schist. The light mineral fraction was analysed using the methods described by Hayes and Klugman[9] and the results plotted in Fig. 2. The volcanic glass has a refractive index of 1.496–1.500. Wet chemical analysis has been done on both the whole rock and pure glass shard fraction (Table 2). K–Ar dating was done on biotite and gave an age of $74.9 \pm 12 \times 10^3$ yr (Table 3).

Table 1 Composition of the heavy mineral fraction (%) in the Toba welded tuff and in the ash layer from Tampan and deep-sea cores (size fraction: 0.25–0.062 mm)

1. TOBA (Si Gura Gura, Id 680); whole rock.
2. TOBA (Si Gura Gura, Id 680); glass shard fraction.
3. Deep-sea core RC14-37; ash layer at 100–115 cm, glass shard fraction.
4. Kota Tampan, Malaya; volcanic ash (UM6315); glass shard fraction.

The pumice tuff (72-0-60) sample was collected by J. D. Obradovich at Prapat (Fig. 1), where in 1972 an excavation above the lake exposed some 10 m of pumice tuff. The pumice fragments (5–10 cm) are predominantly glass with phenocrysts (2–4 mm) of quartz, sanidine, black biotite and brown hornblende; zircon was also recovered. No xenoliths are present.

K-Ar dating was done on sanidine and gave an age of $73.5 \pm 3 \times 10^3$ yr (Table 3). Because the radiogenic argon content for the analysis on sanidine is so much greater than that of the biotite analysis this result is considered to be the most reliable.

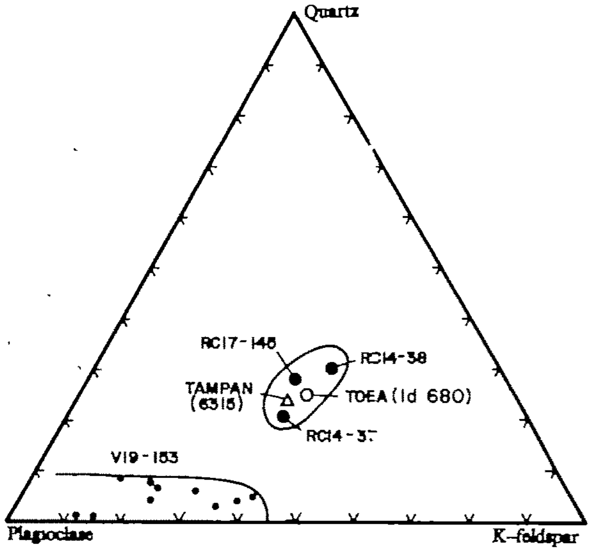
Toba ash layer in deep-sea cores

Fifteen deep-sea cores (Fig. 1) contain a single ash layer. Glass shards from the ash layer in all cores have a refractive index of 1.496–1.500, similar to that of the Toba tuff. Mineralogical composition of the deep-sea ash layer is also similar to the Toba sample (Table 1, Fig. 2). Chemical composition of the glass shard fraction from the ash in core RC14-37 is given in Table 2.

RC14-37 was taken from the top of the 90° E ridge. The ash layer, graded from the bottom upwards, occurs at 100–115 cm (Fig. 3). The core is composed of about 85% $CaCO_3$, and shows very little variation throughout the sediment.

Oxygen isotope measurements were made in *Globigerinoides*

Fig. 2 Correlation of upper Toba tuff with ash layer from Tampan, Malaya and deep-sea cores RC14-37, RC14-38 and RC17-145, based on light mineral composition.



sacculifer with a view to establishing the position of the ash layer in the standard oxygen isotope stratigraphy. The measurements (Fig. 3) indicate that the core extends to Stage 13 at about 0.5 Myr. This is confirmed by the observation that Stage 12 is bracketed by the extinction of *P. lacunosa* below[11], and *S. universus* above[12]. The Toba ash layer is found at about the Stage 5–4 boundary (Fig. 3). The age of the Stage 5–4 boundary is generally agreed to be ~75,000 yr (ref. 13).

The recognition of the Toba ash in core RC14-37 and its K–Ar age of $73.5 \pm 3 \times 10^3$ yr allows an independent assessment of the age of the Stage 4–5 boundary. As the ages of the stage boundaries given by Shackleton and Opdyke[13] are estimated on the basis of a uniform sedimentation rate in core V28-238 calibrated by the presence of the Brunhes–Matuyama magnetic epoch boundary, age 700,000 yr, our results confirm that this assumption is valid.

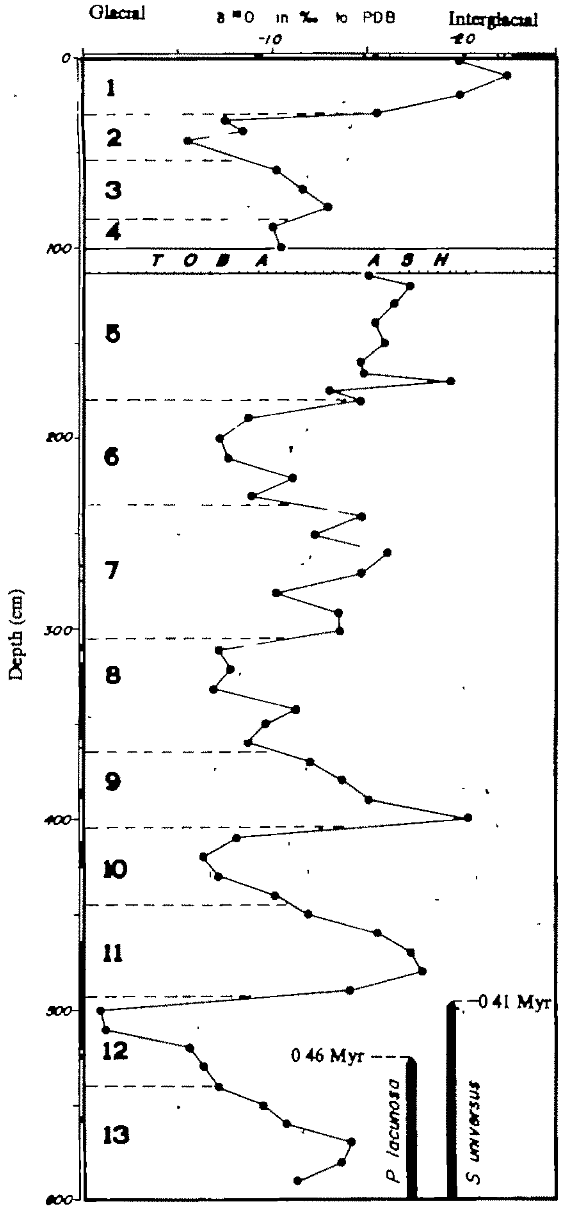


Fig. 3 Core RC14-37. Oxygen isotope curve, and coccolith *P. lacunosa* and radiolarian *S. universus* extinction levels (after refs 11 and 12). Toba ash occurs at about the $\delta^{18}O$ Stage 4–5 boundary.

Volcanic ash from Kota Tampan

Volcanic ash, up to 3 m thick was first reported from the Kota Tampan area in west Malaya by Scrivenor[14] and suggested by van Bemmelen[4] to have originated in the Toba eruption. This ash has received much attention, particularly because it covers gravels from an ancient river terrace in which Palaeolithic tools have been found[15] (Fig. 4). The tools have been studied archaeologically by Collings[15], Sieveking[16], and more recently by Harrison[17], who questions the validity of the Tampan artefacts.

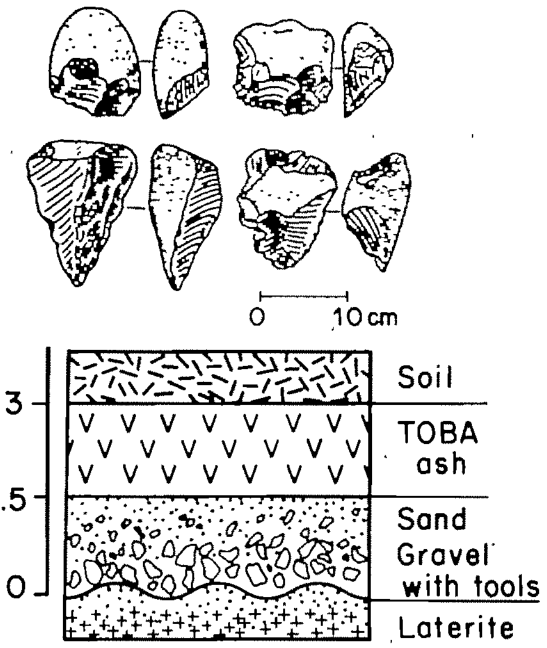

Fig. 4 Tampan Palaeolithic tools and their stratigraphic position (after ref. 15)

An age of about 35,000 yr for the Tampan Palaeolithic tools, attributed by Harrison, is based on ^{14}C dating of wood reported by Stauffer[18]. Three samples of wood found under the ash have been dated and gave the following ages: 33,250 ± 1,800, 36,500 ± 2,500, and greater than 39,000 yr BP. One sample of wood found above the ash layer gave an age of 1,145 ± 90 yr BP (ref. 18). In view of our results, however, it seems likely that the two samples that yielded apparently finite ^{14}C ages were contaminated by recent carbon (see Stuiver et al.[19] for an up to date discussion of contamination of samples by modern carbon).

Several samples of Tampan ash were provided by N. Haile. The following four samples have been analysed: UM6312 and 6313 (100°58′40″ E, 5°3′30″ N), UM6315 (100°57′50″ E, 5°3′25″ N) and UM6317 (100°57′30″ E, 4°49′10″ N). Volcanic glass shards from all samples have a refractive index similar to that of the Toba tuff (Id 680). Chemical composition of the

samples is given in Table 1 and relative proportions of light minerals in Fig. 2.

The relative proportions of light minerals in sample UM6315 is similar to that of the Toba tuff and the deep-sea ash layer. The chemical composition of the pure glass shard fraction of sample UM6315 is given in Table 2. The three other samples have a higher quartz content, and contain a small per cent of tourmaline, suggesting contamination by residual sand.

Electron microprobe analysis for seven elements has been done on volcanic glass shards and sanidine from the Tampan sample UM6313 and Toba sample 72–0–60 and those data are plotted as gross counts in Fig. 5. The match for these seven elements is exceedingly good. The sanidine phenocrysts of both samples are notable in that they have an extremely high value for K_2O of 11.9% based on isotope dilution analysis of sample 72–0–60.

Volcanic ash layers in deep-sea cores near Sunda Strait

Several piston cores containing rhyolitic ash layers have been taken to the south-west of Sunda Strait[20], a few hundred kilometres from the rhyolitic tuff fields of south Sumatra and west Java. Core V19–153 contains 10 ash layers, whose age and chemical composition have been reported by Ninkovich[1].

The compositions of the light mineral fraction from 10 ash layers in core V19–153 are shown in Fig. 2, for comparison with the Toba products. It is obvious from these data that the source of the ash in Malaya and in core RC14–37 is in Toba and not the same as the source of the ash in the more southerly cores.

Conclusion

Sample Id680 from Si Gura Gura taken near the top of the Toba tuffs and the ash layer in deep-sea core RC14–37 have a similar chemical and mineralogical composition. K–Ar dating of the Toba tuff sample Id 680 from Si Gura Gura and sample 72–0–60 from Prapat, and oxygen isotope and biostratigraphic dating of the ash layer in core RC14–37 have provided a similar estimate of about 75,000 yr for the age of the eruption. Examination of core RC14–37 indicates that the 75,000 BP eruption was the only major explosive eruption of Toba in the past 0.5 Myr. Chemical and mineralogical composition of the thick Tampan ash suggests its source was also the 75,000 yr old Toba eruption. The K–Ar age of 73.5 ± 3 × 10³ yr obtained for sanidine from the eruption provides a valuable independent check on the age of the Stage 5–4 boundary in the standard oxygen isotope stratigraphy.

Toba tuff sample Id 680 was provided by Dr M. T. Zen, and ash samples from Malaya by Professor N. Haile. The manuscript was reviewed by F. McCoy and L. H. Burckle. The research was partly funded by NSF grant OCE-76-30690. The core curating facilities at LDGO are supported by the Office of Naval Research (contract N00014-75-C-0210-Scope E) and the NSF (contract OCE-76-18049).

Asymmetric gene conversion at inserted segments on yeast mitochondrial DNA

R. L. Strausberg*, R. D. Vincent†, P. S. Perlman†‡ & R. A. Butow*

Different molecular weight forms of the protein product of the yeast mitochondrial gene var1 *are shown to arise by a process of asymmetric gene conversion. These different forms can be accounted for by two DNA segments, ~36 and 57 base pairs long, present in one allelic form of the* var1 *structural gene, which can be inserted independently and at different frequencies into other* var1 *alleles.*

THE mitochondrial genome of bakers' yeast *Saccharomyces cerevisiae* has been the subject of intensive genetic and biochemical investigation. The genome is apparently highly active in genetic recombination and many phenomenological aspects of the recombination, transmission and segregation of mitochondrial genes have now been well defined (see ref. 1 for a review). However, there is still little information available concerning the molecular mechanisms underlying these proces-

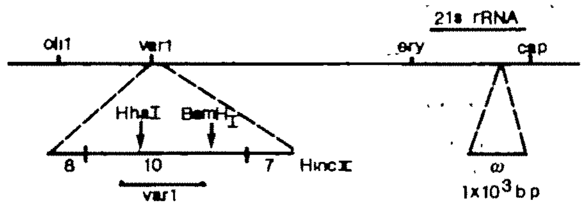

Fig. 1 Diagrammatic representation of the *cap–oli^r1* region of the yeast mitochondrial genome, showing the relative locations of the *var1* gene and the ω insertion, to markers for chloramphenicol resistance (*cap^r*), erythromycin resistance (*ery^r*) and oligomycin resistance (*oli^r1*). *Cap* and *ery* are located in the region encoding the 21S mitochondrial ribosomal RNA; this region is separated from *oli1* by a distance of 11×10^3 base pairs. The determinant ω, an insertion of 1,000 base pairs[10,11], is located within the 21S ribosomal DNA segment. Yeast strains whose mtDNA contains the insertion are termed ω^+; those whose mtDNA lacks it, ω^-.

ses. We know that in most cases, mitochondrial genetic markers are transmitted coordinately to the diploid progeny of crosses. Furthermore, markers tend to segregate rapidly during vegetative growth and for most alleles, reciprocal recombinant genotypes are recovered in equal numbers[2–6]. A well established exception to this last point involves a determinant located in the 21S ribosomal DNA region of the mitochondrial genome designated ω (refs 7, 8) (Fig. 1). Crosses having the configuration $\omega^+ \times \omega^-$ (termed heteropolar) produce grossly unequal numbers of genotypes recombinant for the genetic markers in the vicinity of the ribosomal DNA region[7–9]. Physical mapping studies of mitochondrial DNA (mtDNA) in yeast strains with ω^+ and ω^- alleles show that mtDNA from ω^+ strains has an insertion of 1,000 base pairs near the markers *cap* and *ery* (Fig. 1) that is absent from mtDNA of ω^- strains[10,11]. The major consequence of this difference seems to be a polarity of recombination in the ribosomal DNA region as a result of gene conversion events in the direction ω^- to ω^+. Thus, the 1,000-base pair insertion spreads in heteroplasmic cells among the population of mtDNA molecules. In homopolar crosses, where both parents have the same ω allele, either ω^- or ω^+, no polarity of recombination is observed[8].

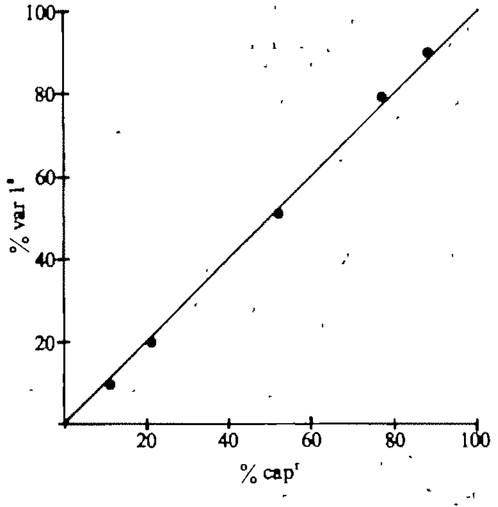

Fig. 2 Calibration curve for an assay of the ratio of *var1* alleles in mixed cell populations. Two diploid segregants of genotype *cap^r var1^S* (Mw 44,000) and *cap^s var1^F* (Mw 40,000) were obtained from the cross 5DSS (*cap^s var1^S*) × 195D (*cap^r var1^F*). These were grown to log phase at 28° C in YEP medium (1% yeast extract, 1% bactopeptone) containing 2% dextrose and were then mixed in various proportions. To determine the exact percentage of each cell type in the mixed cell population, an aliquot was plated on YEP medium containing 2% dextrose and then replica plated on to YEP medium containing 3% glycerol and 3 mg ml^{-1} chloramphenicol. Mitochondrial translation products of each mixed cell population were labelled *in vivo* with $^{35}SO_4^{2-}$ and analysed on SDS–polyacrylamide gels according to the procedure of Douglas and Butow[15]. The autoradiogram of the SDS–polyacrylamide gel was traced with a quick scan densitometer (Helena) and the gaussian curves representing var1 polypeptide were quantitated with a Dupont curve resolver.

Several other strain-specific differences involving various combinations of insertions and deletions in wild-type (ρ^+) mtDNA have been noted[11,12]. These seem to involve DNA segments from <100 to >1,000 base pairs. Fonty *et al.*[13] have reported that when two ρ^+ strains differing in *Hae*III and *Hpa*II restriction endonuclease fragment patterns are mated, a portion of the diploid progeny have one or more restriction fragments that are non-parental. It was suggested that these 'new' bands arise as a result of unequal crossing-over in dAT 'spacer' sequences known to comprise about 50% of the mtDNA in *S. cerevisiae*[14].

We have previously described a product of mitochondrial protein synthesis with novel properties[15]. When mitochondrially synthesised proteins from different ρ^+ yeast strains were analysed on SDS–polyacrylamide gels, most of the major mitochondrial translation products (three subunits of cytochrome oxidase, and the presumed apoprotein of cytochrome *b*) had identical mobilities in all strains. However, a protein termed var1, not previously associated with any mitochondrial function, was found to vary in electrophoretic mobility among the different ρ^+ strains analysed. Thus far, we have identified at least six strain-dependent forms of the var1 polypeptide ranging in molecular weight from 40,000 to 44,000 which are stable during vegetative growth[16]. This polymorphism was used as a genetic marker to show that the structural gene for the polypeptide is located on mtDNA between the markers *ery* and *oli1* (ref. 17) (Fig. 1). By a combination of petite deletion mapping, zygotic gene rescue[18], and restriction endonuclease analysis of ρ^+ and petite mtDNA samples, we have located the structural gene for the var1 polypeptide to a DNA fragment about 2×10^3 base pairs in length, beginning 9.7×10^3 base pairs from a unique *Sal*I site on mtDNA in ω^- strains and 10.7×10^3 base pairs from the same *Sal*I site in ω^+ strains[16] (R.D.V. *et al.*, unpublished data). An important conclusion drawn from our studies was that the variant forms are the result of sequence length differences in the *var1* structural gene itself.

In this report we present a detailed analysis of the origin of different forms of var1 polypeptide. The results provide a satisfying explanation for the apparent widespread polymorphism exhibited by this protein and may be of general significance concerning genetic exchanges in yeast mtDNA. The data demonstrate, at the molecular level, a process of asymmetric intragenic gene conversion which can occur in crosses at a frequency at least equal to that of the observed upper limit of recombination between unlinked mitochondrial markers[4]. The gene conversion events can result in either the conversion of one parental allele to the other, or the formation of new, non-parental forms of the *var1* gene. Although these events at *var1* are assayed differently from those at ω, there is a great similarity between the types of gene conversion exhibited at these two regions of the mitochondrial genome.

Assay for var1 polypeptides in mixed cell populations

In our previous genetic studies, the distribution in crosses of different forms of var1 polypeptide was studied by first isolating homoplasmic diploids and then analysing the individual diploid clones for their drug resistance and *var1* alleles[16,17]. Because the *var1* allele must be determined by analysis of mitochondrial translation products on SDS–polyacrylamide gels, the procedure becomes quite cumbersome for scoring *var1* transmission in a large number of crosses. Consequently, to facilitate the studies described here, we determined whether it was possible to measure quantitatively the relative amounts of different molecular weight forms of *var1* polypeptide in mixed cell populations.

To this end, we carried out a reconstruction experiment in which two isonuclear diploid clones, one of genotype *cap^r var1*

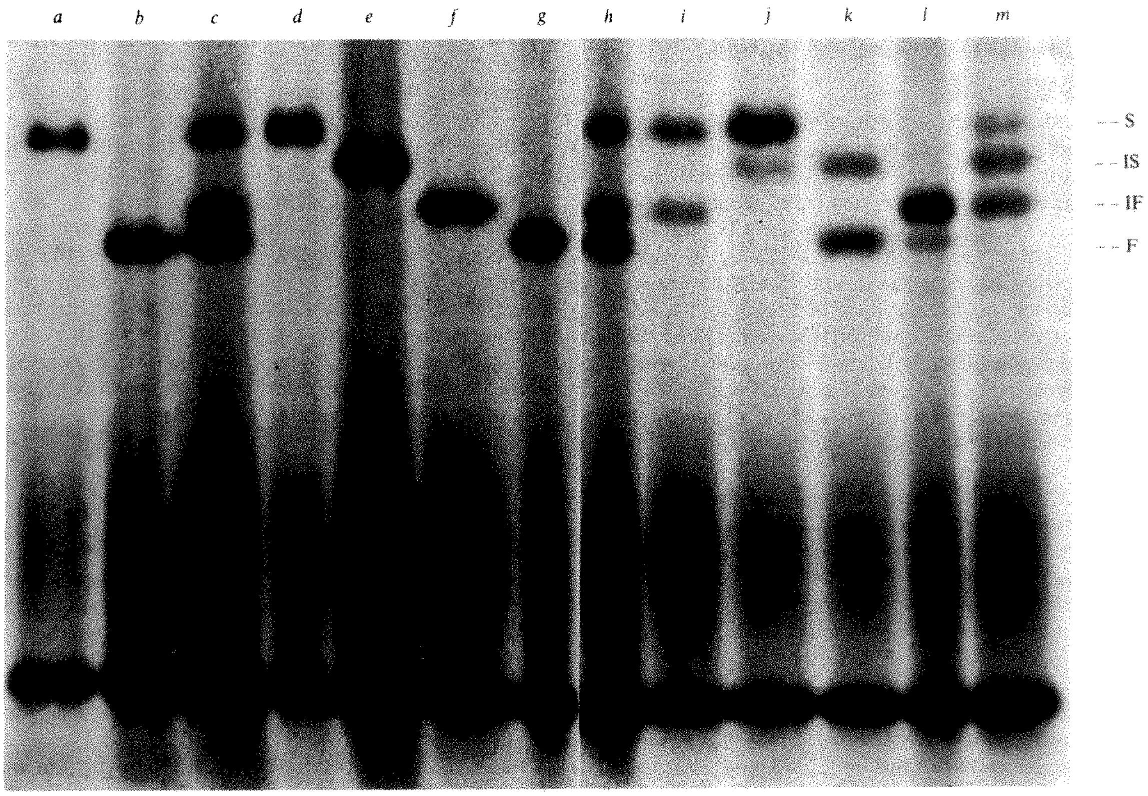

Fig. 3 Analysis of var1 polypeptide in crosses. Wild-type strain 5DSS (a *ura* ω^+ cap^s ery^r oli^s $var1^S$) and 195D (α *ade* '*ys* ω^+ cap^r ery^s oli^r $var1^F$) were mated. Random diploid[7] as well as homoplasmic diploid clones were obtained and their mitochondrial translation products analysed as indicated in Fig. 2. The *var1* alleles for the haploid strains 5DSS and 195D are shown in lanes *a* and *b*, respectively. Random diploid progeny from the cross are shown in lane *c*. Homoplasmic diploid segregants containing the four progeny *var1* types ($var1^S$, $var1^{IS}$, $var1^{IF}$, and $var1^F$) are shown in lanes *d–g*, respectively. These diploid segregants were sporulated and haploid products representing each of the four *var1* forms were obtained with the appropriate nuclear markers so that all possible pairwise crosses could be carried out. In addition, the mitochondrial marker configuration in each case was such that the *ery* and *oli1* alleles could be scored. Lanes *h–l* represent the mitochondrial translation products of a sample of random diploid progeny issued from the following crosses: lane *h*, $var1^F \times var1^S$; lane *i*, $var1^S \times var1^{IF}$; lane *j*, $var1^S \times var1^{IS}$; lane *k*, $var1^{IS} \times var1^F$; lane *l*, $var1^{IF} \times var1^F$; lane *m*, $var1^{IF} \times var1^{IS}$.

(Mw 44,000) and the other cap^s *var1* (Mw 40,000), were mixed in different ratios and each mixed cell population labelled with $^{35}SO_4^{2-}$ in the presence of cycloheximide and products of mitochondrial protein synthesis displayed on SDS–polyacrylamide gels. Densitometer tracings of autoradiograms of the gel were analysed to determine the ratios of the two different molecular weight forms of var1 polypeptide; these were then compared to the input ratios of cell types determined by the proportion of cap^r to cap^s cells. As shown in Fig. 2, there is an excellent linear relationship between the proportion of the two cell types as determined by the *cap* marker and the proportion of var1 polypeptides, thus validating the assay of different forms of the protein in mixed cell populations.

Table 1 The generation of new forms of var1 polypeptide does not depend on outside marker (*ery*, *oli1*) exchange

Genotype	% of total diploids	% of output $var1^S + var1^F$	 $var1^{IF}$
Parental (ery^r oli^s + ery^s oli^r1	71	68	32
Recombinant (ery^s oli^s + ery^r oli^r1)	29	73	27

Homoplasmic diploid segregants were isolated from the cross 5DSS (ω^+ ery^r oli^s $var1^S$) × 195D (ω^+ ery^s oli^r1 $var1^F$) and scored for the *ery* and *oli1* loci. 200 segregants of each parental (ery^r oli^s, ery^s oli^r1) and recombinant (ery^r oli^r1, ery^s oli^s) genotypes were obtained and the percentage of each *var1* type among the progeny was quantitated using a mixed population assay (Fig. 2).

Non-parental forms of var1 polypeptide appear in the progeny of some crosses

Analysis of the transmission of the var1 gene in crosses between strains with different var1 alleles led to the unexpected finding that in some crosses, progeny with non-parental forms of var1 polypeptide are obtained. The most striking example is seen in the random diploid progeny from the cross between strains 5DSS and 195D (Fig. 3) which carry respectively, the largest (44,000) and the smallest (40,000) molecular weight forms of the protein detected thus far. For ease of discussion, we refer to the 44,000 molecular weight species as the S (slow) form and the 40,000 molecular weight species as the F (fast) form.

In the random diploid progeny obtained from this cross, about 30% of the total var1 polypeptide occurs as a non-parental form, with a mobility intermediate between the two parental types, corresponding to an apparent molecular weight of 41,800 (Fig. 3). We subcloned the mixed progeny of the cross and scored *var1* alleles in 60 homoplasmic diploid clones. In addition to the two parental and the 41,800 molecular weight forms, we found two clones with another non-parental form of var1 polypeptide of molecular weight 42,200. Examples of the two parental and two non-parental types of homoplasmic diploid progeny are shown in Fig. 3. These new forms of var1 polypeptide are designated IF (intermediate, fast) for the 41,800 species and IS (intermediate, slow) for the 42,200 species. These are the only non-parental forms of var1 polypeptide that we have observed among 300 individual diploid progeny analysed from this cross.

The generation of new forms of var1 polypeptide does not depend on outside marker exchange

For most mitochondrial genes, separation of pairs of alleles by roughly 10,000 base pairs or more is sufficient to yield a recombination frequency of 20–25%, the upper limit generally being observed. The formation of IF is striking, as it occurs at about that frequency even though the structural gene is contained within a DNA segment no greater than about 2,000 base pairs[16] (R.D.V. *et al.*, unpublished data). If IF and IS arise by recombination, we could account for the data of Fig. 3 by invoking high-frequency reciprocal recombination, for example, at a hot spot within the gene. Alternatively, high-frequency unequal crossing-over or a gene conversion event in which one or both of the parental forms is converted to the new allele at a high rate, could also account for the data.

Because IF and IS are not obtained in equal proportions (about 30% and 2%, respectively) it is unlikely that they are mainly the products of a reciprocal recombination event; this conclusion is supported by the observation that in mixed cell cultures, there is no difference in the growth rates of cells that correlates with *var1* genotype. Unequal crossing-over is also an unlikely mechanism to account for our results as we have never observed new forms of var1 polypeptide in crosses of the type F×F or S×S.

We have examined whether the generation of non-parental forms of var1 polypeptide depends on outside marker exchange. We repeated the cross between strains 5DSS and 195D and selected homoplasmic diploid segregants for each of the four possible genotypes involving the *ery* and *oli1* drug markers which flank the *var1* locus. These are the parental genotypes *ery*^{r} *oli*^{s} and *ery*^{s} *oli*^{r}*1* and the recombinant genotypes *ery*^{r} oli^r*1* and *ery*^{s} *oli*^{s}. To facilitate the analysis, we pooled the individual diploid segregants according to genotype into groups of 20. Ten such groups (of each genotype) were then analysed for the relative distribution of the S, F and IF forms of var1 polypeptide. IS is not generated at a sufficiently high frequency to allow quantitation in this experiment.

The data in Table 1 show that IF comprises about the same fraction of the total *var1* species in either the parental or recombinant classes of progeny. Hence, we can conclude that the generation of IF is independent of any reciprocal crossing-over between its flanking markers. We have also observed that recombination at the *var1* locus is unaffected by interactions of ω^+ and ω^- in heteropolar crosses (data not shown); however, all the crosses reported here are of the homopolar ($\omega^+ + \omega^+$) type.

Non-parental forms of var1 polypeptide arise by gene conversion

Gene conversion can be detected as the loss of one parental allele with a concomitant increase in recovery of the other parental allele or of a recombinant form. To determine if new forms of var1 polypeptide arise by a process of gene conversion, we compared the transmission of the parental alleles with that of the *ery* and *oli1* drug markers. Because, in homopolar crosses, drug markers are recovered coordinately among the progeny, any gene conversion events involving *var1* could be detected as a deviation from coordinate transmission with *ery* and *oli1*. As shown in Table 2 (cross 1) (see Fig. 3), S was transmitted, within experimental error, coordinately with *ery*^{r} and *oli*^{s}. On the other

Fig. 4 *Hinc*II + *Bam*HI restriction endonuclease pattern of mtDNA. mtDNA was prepared from ρ^+ strains 5DSS, 195D and recombinant diploid progeny derived from their mating (see Fig. 3). The mtDNA of each strain was restricted with *Hinc*II + *Bam*HI and electrophoresed on a 2% agarose slab gel for 890 V h, stained for 10 min with 0.5 mg ml^{-1} ethidium bromide and photographed under UV illumination (256 nm). In these electrophoretic conditions, the small *Bam*HI fragment generated from *Hinc*II-10 is not shown because it runs off the gel. Lanes *a* and *h*, ΦX174-RF DNA (combination of digests with *Hpa*II and *Hae*III); lanes *b-g*, mtDNA digested with *Hinc*II + *Bam*HI; lane *b*, strain 5DSS; lane *c*, diploid *var1*^{S}; lane *d*, diploid *var1*^{IS}; lane *e*, diploid *var1*^{IF}; lane *f*, diploid *var1*^{F}; lane *g*, strain 195D. The arrow indicates the large *Hinc*II-10 + *Bam*HI fragment.
